Contents

About This Book ....................................................................................................................... xxiii

CHAPTER 1  DataWindow Operators and Expressions.....................................  1
  Where you use DataWindow expressions........................................ 1
  Operators used in DataWindow expressions ............................ 4
    Arithmetic operators in DataWindow expressions .............. 5
    Relational operators in DataWindow expressions .......... 6
    Logical operators in DataWindow expressions ........... 9
    Concatenation operator in DataWindow expressions .... 10
  Operator precedence in DataWindow expressions ............. 11
  Evaluating DataWindow expressions in scripts.....................  12
  Evaluating DataWindow expressions in the Describe function ...... 13
  Evaluating conditional DataWindow expressions with current data 14

CHAPTER 2  DataWindow Expression Functions ............................................  17
  Using DataWindow expression functions............................... 17
  Four examples : ........................................................................... 19
    Example 1: counting null values in a column .................. 19
    Example 2: counting male and female employees .......... 21
    Example 3: creating a row indicator ................................. 24
    Example 4: displaying all data when a column allows nulls .... 26
  Alphabetical list of DataWindow expression functions ........ 27
    Abs .......................................................... 28
    ACos .......................................................... 28
    Asc .......................................................... 29
    AscA .......................................................... 30
    ASin .......................................................... 30
    ATan .......................................................... 31
    Avg .......................................................... 32
    Bitmap .......................................................... 34
    Case .......................................................... 35
    Ceiling ......................................................... 36
    Char .......................................................... 37
Contents

CharA ................................................................. 38
Cos ..................................................................... 38
Count ................................................................. 39
CrosstabAvg ...................................................... 41
CrosstabAvgDec ................................................ 45
CrosstabCount ................................................... 46
CrosstabMax ...................................................... 47
CrosstabMaxDec ............................................... 49
CrosstabMin ...................................................... 50
CrosstabMinDec ............................................... 52
CrosstabSum ...................................................... 53
CrosstabSumDec ............................................... 54
CumulativePercent .......................................... 55
CumulativeSum ................................................ 57
CurrentRow ..................................................... 59
Date ................................................................. 60
DateTime ........................................................ 61
day ................................................................. 62
DayName ......................................................... 62
DayNumber ...................................................... 63
DaysAfter ....................................................... 64
dec ................................................................. 64
Describe .......................................................... 65
Exp ................................................................. 66
Fact ............................................................... 67
Fill ................................................................. 67
FillA .............................................................. 68
First .............................................................. 69
GetRow ........................................................... 71
GetText ........................................................... 72
Hour .............................................................. 72
If ................................................................. 73
Int ................................................................. 74
Integer ........................................................... 74
IsDate ............................................................ 75
IsExpanded ..................................................... 76
IsNull ........................................................... 76
IsNumber ....................................................... 77
IsRowModified ............................................... 78
IsRowNew ..................................................... 78
IsSelected ..................................................... 79
IsTime ........................................................... 79
Large ........................................................... 80
Last ............................................................... 82
Contents

LastPos ................................................................................... 84
Left ...................................................................................... 85
LeftA .................................................................................... 86
LeftTrim ............................................................................... 86
Len ..................................................................................... 87
LenA .................................................................................... 87
Log ..................................................................................... 88
LogTen ............................................................................... 88
Long .................................................................................... 89
LookUpDisplay ..................................................................... 90
Lower .................................................................................. 90
Match .................................................................................. 91
Max ..................................................................................... 94
Median ............................................................................... 96
Mid ..................................................................................... 98
MidA ................................................................................... 99
Min .................................................................................... 100
Minute ............................................................................... 102
Mod ................................................................................... 102
Mode .................................................................................. 103
Month .................................................................................. 105
Now .................................................................................... 106
Number .............................................................................. 107
Page ................................................................................... 107
PageAbs ............................................................................. 108
PageAcross ......................................................................... 109
PageCount .......................................................................... 109
PageCountAcross ................................................................ 110
Percent ............................................................................... 110
Pi ....................................................................................... 113
Pos .................................................................................... 114
PosA .................................................................................. 115
ProfileInt ........................................................................... 115
ProfileString ....................................................................... 117
Rand ................................................................................... 118
Real .................................................................................... 119
RelativeDate ........................................................................ 120
RelativeTime ....................................................................... 120
Replace ............................................................................... 121
ReplaceA ............................................................................ 122
RGB ................................................................................... 122
Right ................................................................................... 124
RightA ................................................................................. 125
RightTrim ............................................................................. 125
CHAPTER 3 DataWindow Object Properties .............................................. 153

Overview of DataWindow object properties ........................................ 153
Controls in a DataWindow and their properties ................................ 155
Properties for the DataWindow object .................................................. 155
Properties for Button controls in DataWindow objects .................. 159
Properties for Column controls in DataWindow objects .............. 161
Properties for Computed Field controls in DataWindow objects .. 162
Properties for Graph controls in DataWindow objects ............ 163
Properties for GroupBox controls in DataWindow objects ... 165
Properties for the Group keyword ...................................................... 166
Properties for InkPicture controls in DataWindow objects..... 166
Properties for Line controls in DataWindow objects............... 167
Properties for OLE Object controls in DataWindow objects .. 167
Properties for Oval, Rectangle, and RoundRectangle controls in DataWindow objects .................................................. 168
Properties for Picture controls in DataWindow objects ........... 169
Properties for Report controls in DataWindow objects .......... 170
## Contents

- Properties for the Style keyword ........................................... 171
- Properties for TableBlob controls in DataWindow objects .... 171
- Properties for Text controls in DataWindow objects.......... 172
- Title keyword ................................................................. 173
- Alphabetical list of DataWindow object properties .............. 174
  - Accelerator ................................................................. 175
  - AccessibleDescription ................................................ 176
  - AccessibleName .......................................................... 176
  - AccessibleRole ............................................................ 177
  - Action ........................................................................ 178
  - Activation .................................................................. 180
  - Alignment .................................................................... 181
  - Arguments .................................................................. 182
  - Attributes ................................................................... 182
  - Axis ............................................................................ 183
  - Axis.property ................................................................ 184
  - BackColor ..................................................................... 188
  - Background.property .................................................. 188
  - BackImage .................................................................... 192
  - Band ............................................................................. 192
  - Bandname.property ..................................................... 193
  - Bandname.Text ............................................................ 197
  - Bands .......................................................................... 198
  - BinaryIndex ................................................................... 199
  - BitmapName .................................................................. 199
  - Border .......................................................................... 199
  - Brush.property ................................................................ 201
  - Brushmode .................................................................... 202
  - Category ........................................................................ 204
  - CheckBox.property ....................................................... 204
  - ClientName .................................................................... 206
  - Color ............................................................................ 207
  - ColType .......................................................................... 208
  - Column.Count ................................................................ 210
  - ContentsAllowed ........................................................ 210
  - Criteria .......................................................................... 211
  - Criteria.property .......................................................... 212
  - Crosstab.property ........................................................... 213
  - CSSGen.property ............................................................ 215
  - Data ............................................................................... 216
  - Data.HTML ..................................................................... 217
  - Data.HTMLTable ............................................................ 218
  - Data.XHTML .................................................................. 219
  - Data.XML ....................................................................... 220
Contents

LinkUpdateOptions .......................................................... 319
Message.Title ................................................................. 320

Zoom .......................................................................... 415

CHAPTER 4 Accessing Data in Code ....................................................... 417
Accessing data and properties in DataWindow programming
  environments ............................................................... 417
Techniques for accessing data ........................................ 418
  About DataWindow data expressions ............................ 419
Syntaxes for DataWindow data expressions ...................... 426
  Syntax for one or all data items in a named column ......... 427
  Syntax for selected data in a named column .................. 430
  Syntax for a range of data in a named column ............... 431
  Syntax for a single data item in a DataWindow ............... 432
  Syntax for data in a block of rows and columns ............ 433
  Syntax for data in a single row or all rows ................... 436
  Syntax for all data from selected rows ........................ 438

CHAPTER 5 Accessing DataWindow Object Properties in Code ............. 439
About properties of the DataWindow object and its controls .... 439
  What you can do with DataWindow object properties ....... 440
  Specifying property values in the DataWindow painter ....... 442
  Accessing DataWindow object property values in code .... 442
  Using DataWindow expressions as property values ........ 443
  Nested strings and special characters for DataWindow object
    properties ............................................................... 446

</table>

### CHAPTER 7 Properties of the DataWindow Control and DataStore .......... 491
- Properties for PowerBuilder DataWindow .................. 491
- Properties for DataStore objects ......................... 492
- Properties for DataWindow controls ..................... 492
- Properties for the Web DataWindow server component ..... 495
- Properties for the Web ActiveX control .................. 498

### CHAPTER 8 DataWindow Events .............................................. 499
- About return values for DataWindow events .............. 499
- Categories of DataWindow events .......................... 500
- DataWindow event cross-reference ......................... 502
- Alphabetical list of DataWindow events ................... 503
- BackTabOut .......................................................... 503
- ButtonClicked ....................................................... 504
- ButtonClicking ..................................................... 506
- Clicked ................................................................. 507
- Collapsed ............................................................. 510
- Collapsing ............................................................. 511
- Constructor ........................................................... 512
- DBError ................................................................. 512
- Destructor ............................................................. 515
- DoubleClicked ......................................................... 516
- DragDrop ............................................................... 518
- DragEnter ............................................................. 519
- DragLeave ............................................................. 520
- DragWithin ............................................................ 520
- DropDown ............................................................... 521
- EditChanged ........................................................... 522
- Error ..................................................................... 522
- Expanded ............................................................... 525
- Expanding ............................................................ 526
- GetFocus ............................................................... 527
- GraphCreate .......................................................... 527
- HTMLContextApplied ............................................... 528
- ItemChanged .......................................................... 529
- ItemError .............................................................. 530
- ItemFocusChanged .................................................... 532
- KeyDown ................................................................. 534
Contents

DataWindow Reference .......................................................... xxix
## About This Book

**Subject**
This book provides reference information for the DataWindow® object. It lists the DataWindow functions and properties and includes the syntax for accessing properties and data.

**Audience**
This book is for anyone defining DataWindow objects and writing scripts that deal with DataWindow objects. It assumes that:

- You are familiar with the DataWindow painter. If not, see the PowerBuilder® Users Guide.
- You have a basic familiarity with PowerScript®. If not, see the PowerScript Reference.

**Related documents**
For a complete list of PowerBuilder documentation, see the preface of PowerBuilder Getting Started.

**Two volumes**
The printed version of this book is divided into two volumes:
- Volume 1 includes Chapters 1-8.
- Volume 2 includes Chapters 9-11.

**Other sources of information**
Use the Sybase Getting Started CD, the SyBooks CD, and the Sybase Product Manuals Web site to learn more about your product:

- The Getting Started CD contains release bulletins and installation guides in PDF format, and may also contain other documents or updated information not included on the SyBooks CD. It is included with your software. To read or print documents on the Getting Started CD, you need Adobe Acrobat Reader, which you can download at no charge from the Adobe Web site using a link provided on the CD.
- The SyBooks CD contains product manuals and is included with your software. The Eclipse-based SyBooks browser allows you to access the manuals in an easy-to-use, HTML-based format.

Some documentation may be provided in PDF format, which you can access through the PDF directory on the SyBooks CD. To read or print the PDF files, you need Adobe Acrobat Reader.

Refer to the SyBooks Installation Guide on the Getting Started CD, or the README.txt file on the SyBooks CD for instructions on installing and starting SyBooks.
The Sybase Product Manuals Web site is an online version of the SyBooks CD that you can access using a standard Web browser. In addition to product manuals, you will find links to EBFs/Maintenance, Technical Documents, Case Management, Solved Cases, newsgroups, and the Sybase Developer Network.

To access the Sybase Product Manuals Web site, go to Product Manuals at http://www.sybase.com/support/manuals/.

Conventions

The formatting conventions used in this manual are:

<table>
<thead>
<tr>
<th>Formatting example</th>
<th>Indicates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retrieve and Update</td>
<td>When used in descriptive text, this font indicates:</td>
</tr>
<tr>
<td></td>
<td>• Command, function, and method names</td>
</tr>
<tr>
<td></td>
<td>• Keywords such as true and false</td>
</tr>
<tr>
<td>variable or file name</td>
<td>When used in descriptive text and syntax descriptions, oblique font indicates:</td>
</tr>
<tr>
<td></td>
<td>• Variables, such as myCounter</td>
</tr>
<tr>
<td></td>
<td>• Parts of input text that must be substituted, such as pblname.pbd</td>
</tr>
<tr>
<td></td>
<td>• File and path names</td>
</tr>
<tr>
<td>File&gt;Save</td>
<td>Menu names and menu items are displayed in plain text. The greater than symbol (&gt;) shows you how to navigate menu selections. For example, File&gt;Save indicates “select Save from the File menu.”</td>
</tr>
<tr>
<td>dw_1.Update()</td>
<td>Monospace font indicates:</td>
</tr>
<tr>
<td></td>
<td>• Information that you enter in a dialog box or on a command line</td>
</tr>
<tr>
<td></td>
<td>• Sample script fragments</td>
</tr>
<tr>
<td></td>
<td>• Sample output fragments</td>
</tr>
</tbody>
</table>

If you need help

Each Sybase installation that has purchased a support contract has one or more designated people who are authorized to contact Sybase Technical Support. If you cannot resolve a problem using the manuals or online help, please have the designated person contact Sybase Technical Support or the Sybase subsidiary in your area.
CHAPTER 1

DataWindow Operators and Expressions

About this chapter

You use an expression to request that a DataWindow object perform a computational operation. This chapter explains how expressions work and how to write them.

Contents

</tbody>
</table>

Where you use DataWindow expressions

A DataWindow expression is a combination of data, operators, and functions that, when evaluated, results in a value. An expression can include column names, operators, DataWindow expression functions, and constants such as numbers and text strings.

In painters

DataWindow expressions are associated with DataWindow objects and reports. You specify them in the DataWindow painter. You can also specify expressions in the Database painter, although these expressions have a slightly different format and are used only in validation rules.

For information about DataWindow expression functions that you can use in expressions, see “Using DataWindow expression functions” on page 17, or look up the function you want in online Help.
In painters, you use expressions in these ways:

**Table 1-1: Using DataWindow expressions in painters**

<table>
<thead>
<tr>
<th>In this painter</th>
<th>Expressions are used in</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataWindow painter</td>
<td>Computed fields</td>
</tr>
<tr>
<td></td>
<td>Conditional expressions for property values</td>
</tr>
<tr>
<td></td>
<td>Validation rules</td>
</tr>
<tr>
<td></td>
<td>Filters</td>
</tr>
<tr>
<td></td>
<td>Sorting</td>
</tr>
<tr>
<td></td>
<td>Series and values in graphs</td>
</tr>
<tr>
<td></td>
<td>Columns, rows, and values in crosstabs</td>
</tr>
<tr>
<td>Database painter</td>
<td>Validation rules</td>
</tr>
</tbody>
</table>

**Other types of expressions you use**

You also use expressions in Quick Select, SQL Select, and the Query painter to specify selection criteria, and in SQL Select and the Query painter to create computed columns. In these painters you are using SQL operators and DBMS-specific functions, not DataWindow expression operators and functions, to create expressions.

You can access and change the value of DataWindow data and properties in code. The format for expressions you specify in code is different from the same expression specified in the painter. These differences are described in Chapter 4, “Accessing Data in Code” and Chapter 5, “Accessing DataWindow Object Properties in Code.”

Some of the specific places where you use expressions are described here.

**In computed fields**

Expressions for computed fields can evaluate to any value. The datatype of the expression becomes the datatype of the computed field:
CHAPTER 1 DataWindow Operators and Expressions

Table 1-2: Using expressions in computed fields

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Today ()</td>
<td>Displays the date using the Today function</td>
</tr>
<tr>
<td>Salary/12</td>
<td>Computes the monthly salary</td>
</tr>
<tr>
<td>Sum (Salary for group 1)</td>
<td>Computes the salary for the first group using the Sum aggregate function</td>
</tr>
<tr>
<td>Price*Quantity</td>
<td>Computes the total cost</td>
</tr>
</tbody>
</table>

Expressions for graphs and crosstabs
You can use similar expressions for series and values in graphs and for columns, rows, and values in crosstabs.

In filters
Filter expressions are boolean expressions that must evaluate to true or false:

Table 1-3: Using expressions with filters

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Academics = &quot;*****&quot; AND Cost = &quot;$$&quot;</td>
<td>Displays data only for colleges with both a 5-star academic rating and a $$$ cost rating</td>
</tr>
<tr>
<td>Emp_sal &lt; 50000</td>
<td>Displays data for employees with salaries less than $50,000</td>
</tr>
<tr>
<td>Salary &gt; 50000 AND Dept_id BETWEEN 400 AND 700</td>
<td>Displays data for employees in departments 400, 500, 600, and 700 with salaries greater than $50,000</td>
</tr>
<tr>
<td>Month(Bdate) = 9 OR Month(Bdate) = 2</td>
<td>Displays data for people with birth dates in September or February</td>
</tr>
<tr>
<td>Match ( Lname, &quot;[^ABC]&quot; )</td>
<td>Displays data for people whose last name begins with A, B, or C</td>
</tr>
</tbody>
</table>

In validation rules for table columns
Validation rules are boolean expressions that compare column data with values and that use relational and logical operators. When the validation rule evaluates to false, the data in the column is rejected.

In the DataWindow painter
When you specify a validation rule in the DataWindow painter, you should validate the newly entered value. To refer to the newly entered value, use the GetText function. Because GetText returns a string, you also need a data conversion function (such as Integer or Real) if you compare the value to other types of data.

If you include the column name in the expression, you get the value that already exists for the column instead of the newly entered value that needs validating.
In the Database painter When you specify the validation rule in the Database painter, you are defining a general rule that can be applied to any column. Use @placeholder to stand for the newly entered value. The name you use for @placeholder is irrelevant. You can assign the rule to any column that has a datatype appropriate for the comparison. When you define a DataWindow object, a validation rule assigned to a column is brought into the DataWindow object and converted to DataWindow object syntax. @placeholder is converted to GetText and the appropriate datatype conversion function.

Other columns in the rule You can refer to values in other columns for the current row by specifying their names in the validation rule:

### Table 1-4: Using expressions with values from other columns

<table>
<thead>
<tr>
<th>Expression in Database painter</th>
<th>Expression in DataWindow painter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@column &gt;= 10000</td>
<td>Integer(GetText())&gt;=10000</td>
<td>If a user enters a salary below $10,000, an error message displays.</td>
</tr>
<tr>
<td>@column IN (100, 200, 300)</td>
<td>Integer(GetText()) IN (100, 200, 300)</td>
<td>If a user does not enter a department ID of 100, 200, or 300, an error message displays.</td>
</tr>
<tr>
<td>@salary &gt; 0</td>
<td>Long(GetText()) &gt; 0</td>
<td>If a user does not enter a positive number, an error message displays.</td>
</tr>
<tr>
<td>Match(@disc_price, &quot;^[0-9]+$&quot;) and @disc_price &lt; Full_Price</td>
<td>Match(GetText(), &quot;^[0-9]+$&quot;) and Real(GetText()) &lt; Full_Price</td>
<td>If a user enters any characters other than digits, or the resulting number is greater than or equal to the value in the Full_Price column, an error message displays.</td>
</tr>
</tbody>
</table>

---

**Operators used in DataWindow expressions**

An operator is a symbol or word in an expression that performs an arithmetic calculation or logical operation; compares numbers, text, or values; or manipulates text strings.

Four types of operators are available:

- **Arithmetic** for numeric datatypes. See “Arithmetic operators in DataWindow expressions” on page 5.
CHAPTER 1  DataWindow Operators and Expressions

- **Relational** for all datatypes. See “Relational operators in DataWindow expressions” on page 6.
- **Logical** for all datatypes. See “Logical operators in DataWindow expressions” on page 9.
- **Concatenation** for string datatypes. See “Concatenation operator in DataWindow expressions” on page 10.

### Arithmetic operators in DataWindow expressions

When you write an expression, you can use the following arithmetic operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Addition</td>
<td>SubTotal + Tax</td>
</tr>
<tr>
<td>-</td>
<td>Subtraction</td>
<td>Price - Discount</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication</td>
<td>Quantity * Price</td>
</tr>
<tr>
<td>/</td>
<td>Division</td>
<td>Discount / Price</td>
</tr>
<tr>
<td>^</td>
<td>Exponentiation</td>
<td>Rating ^ 2.5</td>
</tr>
</tbody>
</table>

**Table 1-5: Using expressions with arithmetic operators**

**Multiplication and division**

Multiplication and division are carried out to full precision (16–18 digits). Values are rounded:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.0/3</td>
<td>6.666666666666667</td>
</tr>
<tr>
<td>3*(20.0/3)</td>
<td>20</td>
</tr>
<tr>
<td>Truncate(20.0/3,4)</td>
<td>6.6666</td>
</tr>
</tbody>
</table>

**Calculations with null**

When you form an arithmetic expression that contains a null value, the expression becomes null. Thinking of null as *undefined* makes this easier to understand. For example, when a null column is multiplied by 5, the entire expression also evaluates to null. Use the IsNull function to explicitly check for the null value.

Boolean expressions that contain a null value evaluate to *false* rather than to null. For more information, see “Relational operators in DataWindow expressions” next.
Relational operators in DataWindow expressions

You use relational operators to compare a value with other values. The result is a boolean expression whose value is always true or false.

Since the result of a boolean expression is always true or false, a relational operator that compares a value to null evaluates to false. For example, the expression “column > 5” evaluates to false (and “NOT column > 5” evaluates to true) when the column value is null.

When you write an expression, you can use the following relational operators (more information about LIKE, IN, and BETWEEN follows the table):

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Is equal to</td>
<td>Price = 100</td>
</tr>
<tr>
<td>&gt;</td>
<td>Is greater than</td>
<td>Price &gt; 100</td>
</tr>
<tr>
<td>&lt;</td>
<td>Is less than</td>
<td>Price &lt; 100</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Is not equal to</td>
<td>Price &lt;&gt; 100</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
<td>Price &gt;= 100</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal to</td>
<td>Price &lt;= 100</td>
</tr>
<tr>
<td>NOT =</td>
<td>Is not equal to</td>
<td>Price NOT= 100</td>
</tr>
<tr>
<td>LIKE</td>
<td>Matches this specified pattern.</td>
<td>Emp_lname LIKE 'C%' OR Emp_lname LIKE 'G%'</td>
</tr>
<tr>
<td>IN</td>
<td>Is in this set of values.</td>
<td>Dept_id IN (100, 200, 500)</td>
</tr>
<tr>
<td>BETWEEN</td>
<td>Is within this range of values.</td>
<td>Price BETWEEN 1000 AND 3000</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Does not match this specified pattern.</td>
<td>Emp_lname NOT LIKE 'C%', AND Emp_lname NOT LIKE 'G%'</td>
</tr>
<tr>
<td>NOT IN</td>
<td>Is not in this set of values.</td>
<td>Dept_id NOT IN (100, 200, 500)</td>
</tr>
<tr>
<td>NOT BETWEEN</td>
<td>Is outside this range of values.</td>
<td>Price NOT BETWEEN 1000 AND 2000</td>
</tr>
</tbody>
</table>
You can use the following special characters with relational operators that take string values:

**Table 1-8: Special characters for use in expressions with relational operators**

<table>
<thead>
<tr>
<th>Special character</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>% (percent)</td>
<td>Matches any group of characters.</td>
<td>Good% matches all names that begin with Good.</td>
</tr>
<tr>
<td>_ (underscore)</td>
<td>Matches any single character.</td>
<td>Good _ _ _ matches all 7-letter names that begin with Good.</td>
</tr>
</tbody>
</table>

**LIKE and NOT LIKE operators**

Use LIKE to search for strings that match a predetermined pattern. Use NOT LIKE to search for strings that do not match a predetermined pattern. When you use LIKE or NOT LIKE, you can use the % or _ characters to match unknown characters in a pattern.

For example, the following expression for the Background.Color property of the Salary column displays salaries in red for employees with last names beginning with F and displays all other salaries in white:

```
If(emp_lname LIKE 'F%', RGB(255,0,0), RGB(255,255,255))
```

**Escape keyword**

If you need to use the % or _ characters as part of the string, you can use the escape keyword to indicate that the character is part of the string. For example, the _ character in the following filter string is part of the string to be searched for, but is treated as a wildcard:

```
comment LIKE ~'%o_a15progress%~'
```

The escape keyword designates any character as an escape character (do not use a character that is part of the string you want to match). In the following example, the asterisk (*) character is inserted before the _ character and designated as an escape character, so that the _ character is treated as part of the string to be matched:

```
comment like ~'%o*_a15progress%~' escape ~'*~'
```

**BETWEEN and NOT BETWEEN operators**

Use BETWEEN to check if a value is within a range of values. Use NOT BETWEEN to check if a value is not in a range of values. The range of values includes the boundary values that specify the range.

For example, the following expression for the Background.Color property of the Salary column displays salaries in red when an employee’s salary is between $50,000 and $100,000 and displays all other salaries in white:

```
If(salary BETWEEN 50000 AND 100000, RGB(255,0,0), RGB(255,255,255))
```
Operators used in DataWindow expressions

You can use the BETWEEN and NOT BETWEEN operators with string values. For example, if the following expression is used for the Visual property of a column, column values display only for departments listed alphabetically between Finance and Sales:

```plaintext
If(dept_name BETWEEN 'Finance' AND 'Sales',1,0)
```

The % or _ characters can be used when you are using string values with the BETWEEN and NOT BETWEEN operators. This example might include more department listings than the previous example:

```plaintext
If(dept_name BETWEEN 'F%' AND 'S%',1,0)
```

You can also use the BETWEEN and NOT BETWEEN operators with methods. For example:

```plaintext
getRow( ) BETWEEN 5 AND 8
```

IN and NOT IN operators

Use IN to check if a value is in a set of values. Use NOT IN to check if a value is not in a set of values.

For example, the following expression for the Background.Color property of the Salary column displays salaries in red for employees in department 300 or 400 having a salary between $50,000 and $100,000, and displays all other salaries in white:

```plaintext
If(dept_id IN (300,400) and salary BETWEEN 50000 AND 100000, RGB(255,0,0), RGB(255,255,255))
```

Comparing strings in DataWindow expressions

When you compare strings, the comparison is case sensitive. Leading blanks are significant, but trailing blanks are not.

Case-sensitivity examples

Assume City1 is “Austin” and City2 is “AUSTIN”. Then:

```plaintext
City1=City2
```
returns false.

To compare strings regardless of case, use the Upper or Lower function. For example:

```plaintext
Upper(City1)=Upper(City2)
```
returns true.

For information about these functions, see “Using DataWindow expression functions” on page 17.
Blanks examples

Assume City1 is "Austin" and City2 is " Austin ". Then the expression:

\[
\text{City1} = \text{City2}
\]

returns false. PowerBuilder removes the trailing blank before making the comparison, but it does not remove the leading blank.

To prevent leading blanks from affecting a comparison, remove them with one of the trim functions: Trim or LeftTrim.

For example:

\[
\text{Trim(City1)} = \text{Trim(City2)}
\]

returns true.

To compare strings when trailing blanks are significant, use an expression such as the following to ensure that any trailing blanks are included in the comparison:

\[
\text{City1} + "\>" = \text{City2} + "\>"
\]

For information about these functions, see “Using DataWindow expression functions” on page 17.

Logical operators in DataWindow expressions

You use logical operators to combine boolean expressions into a larger boolean expression. The result is always true or false:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT</td>
<td>Logical negation. If A is true, NOT A is false. If A is false, NOT A is true.</td>
<td>NOT Price = 100</td>
</tr>
<tr>
<td>AND</td>
<td>Logical and. A AND B is true if both are true. A AND B is false if either is false.</td>
<td>Tax &gt; 3 AND Ship &lt; 5</td>
</tr>
<tr>
<td>OR</td>
<td>Logical or. A OR B is true if either is true or both are true. A OR B is false only if both are false.</td>
<td>Tax &gt; 3 OR Ship &lt; 5</td>
</tr>
</tbody>
</table>

When you combine two or more boolean expressions to form a new expression, the new expression is either true or false. The following truth table shows how true and false expressions are evaluated to form an expression that is either true or false.
Operators used in DataWindow expressions

For example, if “My dog has fleas” is true and “My hair is brown” is false, then “My dog has fleas OR my hair is brown” is true, and “My dog has fleas AND my hair is brown” is false:

Table 1-10: Combining expressions with logical operators

<table>
<thead>
<tr>
<th>If one expression has this value</th>
<th>And the logical operator is</th>
<th>And if another expression has this value</th>
<th>The resulting expression has this value</th>
</tr>
</thead>

</tr>
<tr>
<td>NOT FALSE</td>
<td>OR</td>
<td>FALSE</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

If you use a logical operator with a boolean function that returns null, the term with the null return value is evaluated as false. If you use the NOT logical operator with a boolean function that returns null, the complete term evaluates to true. For example, NOT gf_boolean () evaluates to true when gf_boolean returns null.

Concatenation operator in DataWindow expressions

The concatenation operator joins the contents of two variables of the same type to form a longer value. You can concatenate strings and blobs.

To concatenate values, you use the plus sign (+) operator.
Using quotes

You can use either single or double quotes in string expressions. For example, the expression "over" + "stock" is equivalent to the expression 'over' + 'stock'.

<table>
<thead>
<tr>
<th>String expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;over&quot; + &quot;stock&quot;</td>
<td>overstock</td>
</tr>
<tr>
<td>Lname + ', ' + Fname</td>
<td>If Lname is Hill and Fname is Craig, then &quot;Hill, Craig&quot;</td>
</tr>
</tbody>
</table>

Operator precedence in DataWindow expressions

To ensure predictable results, operators in DataWindow expressions are evaluated in a specific order of precedence. When operators have the same precedence, they are evaluated from left to right.

The following table lists the operators in descending order of precedence:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>( )</td>
<td>Grouping</td>
</tr>
<tr>
<td>^</td>
<td>Exponentiation</td>
</tr>
<tr>
<td>*, /</td>
<td>Multiplication and division</td>
</tr>
<tr>
<td>+, -</td>
<td>Addition and subtraction; string concatenation</td>
</tr>
<tr>
<td>IN, LIKE, BETWEEN</td>
<td>SQL SELECT statement conditions</td>
</tr>
<tr>
<td>=, &gt;, &lt;, &lt;=, &gt;=, &lt;&gt;</td>
<td>Relational operators</td>
</tr>
<tr>
<td>AND, OR</td>
<td>Logical and and logical or</td>
</tr>
<tr>
<td>NOT</td>
<td>Logical negation</td>
</tr>
</tbody>
</table>

Since expressions in parentheses are evaluated first, to override the precedence order, enclose expressions in parentheses. You can also use parentheses to clarify the order of evaluation. Within each set of parentheses, precedence order applies.

In the expression \( x + y * a + b \), \( y \) is first multiplied by \( a \) (because multiplication has a higher precedence than addition). The result of the multiplication is then added to \( x \) and this result is then added to \( b \) (because the + operators are evaluated left to right).
To force evaluation in a different order, group expressions with parentheses. For example, in the expression $x + (y * (a + b))$, $a + b$ is evaluated first. The sum $a + b$ is then multiplied by $y$, and this product is added to $x$.

**Evaluating DataWindow expressions in scripts**

In a script, you use methods, properties, and data expressions for the DataWindow control to get information about the state of the DataWindow: the current row, the highlighted row, values of particular items. You can get other information by accessing properties of the DataWindow object, either with the Describe function or with property expressions.

For example, if you need to find the current row in a DataWindow, use the DataWindow control function, GetRow:

```powerbuilder
ll_rownum = dw1.GetRow()
```

If you need to find the first row on the current page in a DataWindow, there is no DataWindow control function to return this information, but you can find it in the appropriate DataWindow object property:

```powerbuilder
ls_first = dw1.Object.DataWindow.FirstRowOnPage
ls_last = dw1.Object.DataWindow.LastRowOnPage
dw1.Title = "Rows " + ls_first + " to " + ls_last
```

In some cases, however, information you need might not be available either by using DataWindow control functions or by accessing DataWindow object properties.

DataWindow expression functions sometimes provide information that is available in no other way. These functions, which are available within a DataWindow expression, are documented in “Using DataWindow expression functions” on page 17.
Evaluating DataWindow expressions in the Describe function

The Describe function provides a way to evaluate DataWindow expressions outside their usual context. The Evaluate function, which is used only within Describe, allows you to evaluate DataWindow expressions within a script using data in the DataWindow.

Evaluate has the following syntax:

```
dwcontrol.Describe ("Evaluate ( 'expression' , rownumber ) ")
```

Expression is the expression you want to evaluate and rownumber is the number of the row for which you want to evaluate the expression. The expression can include DataWindow expression functions that cannot be called in a script.

This example displays in the title of the DataWindow control the current page for the current row in the DataWindow:

```plaintext
string ls_modstring, ls_rownum
ls_rownum = String(dw1.GetRow())
ls_modstring = "Evaluate('Page()',' + ls_rownum +')"
// The resulting string, for row 99, would be: // Evaluate('Page()', 99)
Parent.Title = & "Current page: " + dw1.Describe(ls_modstring)
```

This example returns the display value for the dept_id column for row 5:

```
dw1.Describe("Evaluate('LookUpDisplay(dept_id)' , 5)")
```

Expressions that apply to all rows

To evaluate an expression that applies to all rows, specify 0 for the rownumber argument. This example calculates the sum of the salary column in the current DataWindow. It will return the expression’s result or "!" if the expression is not valid:

```
dw1.Describe("Evaluate('Sum(Salary)' , 0)")
```

Evaluating user-specified expressions

In some types of applications, you might use Evaluate to get the result of an expression the user specifies. For example, users might specify the type of aggregation they want to see. This example evaluates an expression specified in a SingleLineEdit. It applies to all rows:

```
dw1.Describe("Evaluate(' + sle_expr.Text + ')' , 0)")
```
Evaluating conditional DataWindow expressions with current data

Querying a property for a column

Values for column properties normally apply to all the rows in the column. For example, if you set the Protect property to “1” for the Emp_Id column, the user will be unable to modify Emp_Id for any of the rows. If you query the property value for this column at runtime, it will return “1”.

When the column has a conditional expression

Instead of a constant, you can assign a conditional expression to some column properties. Such properties are set on a row-by-row basis at runtime.

For example, you might wish to allow users to enter an employee id for new rows but protect this value for existing rows. The conditional expression for this column’s Protect property would be:

\[
\text{If}(\text{IsRowNew}(), 0, 1)
\]

When you query the Protect property at runtime, the result in this case would be the actual expression (preceded by a default value and a tab character and enclosed in quotes) instead of the property value. The value for the Protect property would be:

\[
"0 \text{<tab>} \text{If}(\text{IsRowNew}(), 0, 1)"
\]

Getting a property value for a particular row

To obtain the actual value of the Protect property for a particular row, you need to strip off the default value and the tab and evaluate the returned expression for the desired row. After stripping off the extra information, you can construct an expression for Describe that uses the Evaluate function.

This example checks whether the value of the Protect property for emp_id is a constant or a conditional expression. If it is a conditional expression, the script builds a string for the Describe function that uses Evaluate to get the value for of Protect for the current row:

```powerbuilder
string ls_protect, ls_eval
long ll_row

ll_row = dw1.GetRow()
ls_protect = dw1.Object.id.Protect

IF NOT IsNumber(ls_protect) THEN
    "0 \text{<tab>} \text{If}(\text{IsRowNew}(), 0, 1)"

    // Get the expression following the tab (-t)
    ls_eval = Right(ls_protect, \\
                Len(ls_protect) - Pos(ls_protect, "-t"))
```

PowerBuilder
// Build string for Describe. Include a leading
// quote to match the trailing quote that remains
ls_eval = "Evaluate(" + ls_protect + ", " &
+ String(ll_row) + ")"

ls_protect = dw1.Describe(ls_eval)

END IF

// Display result
st_result.Text = ls_protect
Evaluating conditional DataWindow expressions with current data
CHAPTER 2

DataWindow Expression Functions

About this chapter

This chapter provides syntax, descriptions, and examples of the functions you can use in expressions in the DataWindow painter.

Using DataWindow expression functions

In the DataWindow painter, you can use DataWindow expression functions in expressions for computed fields, filters, validation rules, and graphed data, with some exceptions.

The dialog boxes in which you define expressions include a list box that lists the available functions and their arguments. The dialog boxes make it easy to insert a function into the expression.

For information about expressions, see Chapter 1, “DataWindow Operators and Expressions.”

Return values for functions and expressions

DataWindow expression functions can return the following datatypes:

- Double
- Decimal
- String
- DateTime
- Time

Within an expression, a function can return other datatypes (such as boolean, date, or integer), but the final value of an expression is converted to one of these datatypes.
### Using DataWindow expression functions

#### Restrictions for aggregate functions

An aggregate function is a function (such as `Avg`, `Max`, `StDev`, and `Sum`) that operates on a range of values in a column. When you use an aggregate function, some restrictions apply. You cannot use an aggregate function:

- In a filter
- In a validation rule
- As an argument for another aggregate function

When you use aggregate functions, they cancel the effect of setting Retrieve Rows As Needed. To do the aggregation, the DataWindow object always retrieves all rows.

#### User-defined functions in PowerBuilder

You can include user-defined functions in DataWindow expressions. The datatype of the function’s return value can be any of the following: double, decimal, string, boolean, date, DateTime, or time. The function must be defined as a global function so that it is available to the DataWindow object. However, a global function argument of datatype boolean cannot be provided by a DataWindow expression because it does not map to any of the datatypes listed in “Return values for functions and expressions” on page 17.

Built-in DataWindow expression functions cannot be overridden. For example, if you create a global function called `Today`, it is used instead of the PowerScript system function `Today`, but it is not used instead of the DataWindow expression function `Today`.

#### Formatting for the locally correct display of numbers

No matter what country you are creating objects and developing an application in, you must use U.S. number notation in numbers or number masks in display formats, edit masks, and DataWindow expressions. This means that when you specify a number or number mask, use a comma as the thousands delimiter and period for the decimal place.

Numbers display appropriately in whatever countries you deploy applications in. At runtime, the locally correct symbols for numbers display (because the international Control Panel settings are used) when numbers are interpreted. For example, in countries where comma represents the decimal place and period represents thousands, users see numbers in those formats at runtime.

For information about the locally correct display of dates and day names, see `String` on page 137 and `DayName` on page 62.
Four examples

Example 1: counting null values in a column

A null value is a marker used to fill a place in a column where data is missing for any reason. The value might not be applicable, or it might be missing or unknown. When a database table is created, each column in the table either allows null values or does not allow them. The column or set of columns that define the primary key cannot allow null values. Sometimes it is useful to know how many null values there are in a particular column.

What you want to do

Suppose you are working with the Fin_code table in the Enterprise Application Sample Database. The Fin_code table has three columns:

<table>
<thead>
<tr>
<th>Column</th>
<th>What the column is</th>
<th>Allows null values?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>Unique financial identifier (primary key)</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Code type: expense or revenue</td>
<td>No</td>
</tr>
<tr>
<td>Description</td>
<td>Code description: the department incurring the expense or getting the revenue</td>
<td>Yes</td>
</tr>
</tbody>
</table>

You create a DataWindow object using the Code and Description columns. You want to know the number of null values in the Description column.

How to do it

In the DataWindow object, you create a computed field that uses functions to display the number of null values in the Description column.

For the sake of demonstrating the use of functions, the following computed fields are created in the Summary band of the DataWindow object (with text objects that tell you what information each computed field is providing):

- `Count(description for all)`
  - counts the number of descriptions (that are not null);
- `Sum(If(IsNull(description), 1, 0))`
  - returns a 1 if the description column is null, a 0 if the description column is not null, and then adds the total;
- `Count(id for all)`
  - counts the number of IDs (which is also the number of rows);
Four examples

\[ \text{Sum(If(IsNull(description), 1, 1))} \]

adds the number of nulls and not nulls in the description column (which is the total number of rows) and should match the result of the \( \text{Count( id for all )} \) function; and

\[ \text{IsNull(description)} \]

evaluates whether the last row in the table has a description that is null. The return value of the \text{IsNull} function is \text{true} or \text{false}.

What you get

Here is the design for the DataWindow object.

<table>
<thead>
<tr>
<th>Id</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Number of descriptions</th>
<th>Number of NULLs</th>
<th>Number of rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{count( description for all)} )</td>
<td>( \text{Sum(If(IsNull(description), 1, 0))} )</td>
<td>( \text{count( id for all)} )</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Last value NULL?</th>
<th>( \text{IsNull(description)} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{true}</td>
<td>( \text{Sum(If(IsNull(description), 1, 1))} )</td>
</tr>
</tbody>
</table>

Here is the DataWindow object showing eight descriptions, three of which are null and five of which are not null. The last description for Id=8 is null.

<table>
<thead>
<tr>
<th>Id</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Number of descriptions</th>
<th>Number of NULLs</th>
<th>Number of rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>3</td>
<td>8</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Last value NULL?</th>
<th>\text{true}</th>
</tr>
</thead>
</table>
Example 2: counting male and female employees

Example 1 demonstrates the use of the Sum and Count functions. Sum and Count are two examples of a class of functions called aggregate functions.

An aggregate function is a function that operates on a range of values in a column. The aggregate functions are:

<table>
<thead>
<tr>
<th>Function</th>
<th>Large</th>
<th>Mode</th>
<th>Sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avg</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Count</td>
<td>Last</td>
<td>Percent</td>
<td>Var</td>
</tr>
<tr>
<td>CumulativePercent</td>
<td>Max</td>
<td>Small</td>
<td></td>
</tr>
<tr>
<td>CumulativeSum</td>
<td>Median</td>
<td>StDev</td>
<td></td>
</tr>
<tr>
<td>First</td>
<td>Min</td>
<td>StDevP</td>
<td></td>
</tr>
</tbody>
</table>

About crosstab functions

Although the crosstab functions (CrosstabAvg, CrosstabAvgDec, CrosstabCount, CrosstabMax, CrosstabMaxDec, CrosstabMin, CrosstabMinDec, CrosstabSum, and CrosstabSumDec) behave like aggregate functions, they are not included on the list because they are for crosstabs only and are designed to work in the crosstab matrix.

A few restrictions apply to the use of aggregate functions. You cannot use an aggregate function:

- In a filter
- In a validation rule
- As an argument for another aggregate function

This example demonstrates the use of the Sum aggregate function.

What you want to do

Using the employee table in the EAS Demo DB as the data source, you create a DataWindow object using at least the Emp_id and the Sex columns. You want the DataWindow object to display the number of male employees and female employees in the company.

How to do it

In the summary band in the workspace, add two computed fields to the DataWindow object that use the Sum and If functions:

\[
\text{Sum(If(sex = "M", 1, 0))}
\]

counts the number of males in your company;

\[
\text{Sum(If(sex = "F", 1, 0))}
\]

counts the number of females in your company.
By clicking the Page computed field button, you can also add a Page computed field in the footer band to display the page number and total pages at the bottom of each page of the DataWindow object.

What you get

Here is what the design of the DataWindow object looks like.

<table>
<thead>
<tr>
<th>Employee ID</th>
<th>Sex</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Male</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Number of males</th>
<th>Number of females</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{Sum}([\text{sex} = \text{&quot;M&quot;}], 1, 0]) )</td>
<td>( \text{Sum}([\text{sex} = \text{&quot;F&quot;}], 1, 0]) )</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>( \text{Summary} )</td>
<td>( \text{Footer} )</td>
</tr>
<tr>
<td>( \text{Page} + \text{page}() + \text{&quot; of &quot;} + \text{pageCount}() )</td>
<td></td>
</tr>
</tbody>
</table>

Here is the last page of the DataWindow object, with the total number of males and females in the company displayed.

<table>
<thead>
<tr>
<th>#</th>
<th>Male</th>
<th>Female</th>
</tr>
</thead>
<tbody>
<tr>
<td>1684</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1740</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1751</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Number of males</th>
<th>Number of females</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>34</td>
</tr>
</tbody>
</table>

Page 3 of 3

What if you decide that you also want to know the number of males and females in each department in the company?

❖ To display the males and females in each department:

1. Select Design> Data Source from the menu bar so that you can edit the data source.
2. Select Design> Select tables from the menu bar and open the Department table in the Select painter workspace, which currently displays the Employee table with the Emp_id and Sex columns selected.
3. Select the department_dept_name column to add it to your data source.
4. Select Rows> Create Group from the menu bar to create a group and group by department name.
5 In the trailer group band, add two additional computed fields:
   \[ \text{Sum(If(sex = "M", 1, 0) for group 1)} \]
   counts the number of males in each department;
   \[ \text{Sum(If(sex = "F", 1, 0) for group 1)} \]
   counts the number of females in each department.

Here is what the design of the grouped DataWindow object looks like.

<table>
<thead>
<tr>
<th>Employee ID</th>
<th>Sex</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>department_dept_name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Number of males</th>
<th>Number of females</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sum(If(sex = &quot;M&quot;, 1, 0) for group 1)</td>
<td>Sum(If(sex = &quot;F&quot;, 1, 0) for group 1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Total number of males</th>
<th>Total number of females</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sum(If(sex = &quot;M&quot;, 1, 0))</td>
<td>Sum(If(sex = &quot;F&quot;, 1, 0))</td>
</tr>
</tbody>
</table>

Summary: Page * page() + 'd' + pageCount()

Here is the last page of the DataWindow object with the number of males and females in the shipping department displayed, followed by the total number of males and females in the company.

<table>
<thead>
<tr>
<th>Number of males</th>
<th>Number of females</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>4</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Total number of males</th>
<th>Total number of females</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>34</td>
</tr>
</tbody>
</table>
Example 3: creating a row indicator

This example demonstrates the use of several functions: Bitmap, Case, CurrentRow, GetRow, and RGB.

What you want to do
Using the Employee table in the Enterprise Application Sample Database, you create a DataWindow object using the Emp_id, Emp_fname, Emp_lname, and Salary columns.

In the painter, you want to display a number of items such as the number of the current row, an arrow that is an indicator of the current row, and the salary for an employee with a background color that depends on what the salary is.

How to do it
In the workspace, add the following:

- A computed field CurrentRow(), which displays the number of the current row.
- A picture object, which is a right-arrow, for which you define an expression for the arrow’s visible property:
  
  \[
  \text{If} (\text{CurrentRow()} = \text{GetRow}(), 1, 0) 
  \]
  
  The expression causes an arrow to display in the current row and no arrow to display in other rows.
- A computed field using the If, CurrentRow, and GetRow functions:
  
  \[
  \text{If} (\text{CurrentRow}() = \text{GetRow}(), "\text{Current}", "\text{Not current}") 
  \]
  
  displays the word “Current” when the row is the current row and “Not current” for all other rows.
- A computed field (typed on one line) using the Bitmap, CurrentRow, and GetRow functions:
  
  \[
  \text{Bitmap} (\text{If} (\text{CurrentRow}() = \text{GetRow}(), \\
  "c:sampl\ex\code\indicatr.bmp", "")) 
  \]
  
  displays an arrow bitmap for the current row and no bitmap for all other rows.
- An expression for the Background.Color property of the salary column:
  
  \[
  \text{Case} (\text{salary} \text{ WHEN IS >60000 THEN RGB(192,192,192)} \\
  \text{ WHEN IS >40000 THEN RGB(0,255,0) ELSE RGB(255,255,255))} 
  \]
  
  The expression causes a salary above $40,000 to display in green, a salary above $60,000 to display in gray, and all other salaries to display in white.
CHAPTER 2  DataWindow Expression Functions

What you get

Here is what the design of the DataWindow object looks like:

<table>
<thead>
<tr>
<th>Current Row</th>
<th>Employee ID</th>
<th>First Name</th>
<th>Last Name</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Here is what the data looks like with the second row current.

<table>
<thead>
<tr>
<th>Current Row</th>
<th>Employee ID</th>
<th>First Name</th>
<th>Last Name</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>103</td>
<td>Fran</td>
<td>Whitney</td>
<td>$45,703.00</td>
</tr>
</tbody>
</table>

Not current

<table>
<thead>
<tr>
<th>Current</th>
<th>Employee ID</th>
<th>First Name</th>
<th>Last Name</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>108</td>
<td>Matthew</td>
<td>Cobb</td>
<td>$162,500.00</td>
</tr>
</tbody>
</table>

Not current

<table>
<thead>
<tr>
<th>Current</th>
<th>Employee ID</th>
<th>First Name</th>
<th>Last Name</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>128</td>
<td>Philip</td>
<td>Chin</td>
<td>$38,903.00</td>
</tr>
</tbody>
</table>

Notice that the number of the current row is 2; the first row and the third row are “Not current” (and therefore display no bitmap); and the second row, which is the current row, displays the arrow row indicator.

On your screen, the salary in the first row has a green background because it is more than $40,000; the salary in the second row has a gray background because it is more than $60,000; and the salary in the third row has a white background, which matches the background of the DataWindow object.
Example 4: displaying all data when a column allows nulls

When you create an arithmetic expression that has a null value, the value of the expression is null. This makes sense, since null means essentially undefined and the expression is undefined, but sometimes this fact can interfere with what you want to display.

What you want to do

A table in your database has four columns: Id, Corporation, Address1, and Address2. The Corporation, Address1, and Address2 columns allow null values. Using this table as the data source, you create a DataWindow object using the four columns. You now want the DataWindow object to display both parts of the address, separated by a comma.

You create a computed field to concatenate Address1 and Address2 with a comma separator. Here is the expression that defines the computed field:

```
address1 + ", " + address2
```

When you preview the DataWindow object, if either Address1 or Address2 is null, no part of the address displays because the value of the expression is null. To display a part of the address, you need to create a computed field that forces evaluation even if Address2 is null. Note that Address2 is assumed to have data only if Address1 has data for a particular row.

How to do it

In the detail band, create a computed field that uses the If and IsNull functions:

```
If(IsNull(address1 + address2), address1, address1 + ", " + address2)
```

The computed field says this: if the concatenation of the addresses is null (because address2 is null), then display address1, and if it is not null, display both parts of the address separated by a comma.

What you get

Here is what the design of the DataWindow object looks like. It includes both the computed field that does not work and the one that does.

<table>
<thead>
<tr>
<th>Id</th>
<th>Corporation</th>
<th>Address1</th>
<th>Address2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

`\text{\textbf{Note:}}`
When you preview the DataWindow object, notice that the first computed field displays null for ABC Corporation and XYZ Corporation. The second computed field displays the first part of the address, which is not null.

<table>
<thead>
<tr>
<th>Id</th>
<th>Corporation</th>
<th>Address1</th>
<th>Address2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Sybase, Inc.</td>
<td>561 Virginia Rd.</td>
<td>Concord, MA 01742</td>
</tr>
<tr>
<td></td>
<td></td>
<td>561 Virginia Rd.</td>
<td>Concord, MA 01742</td>
</tr>
<tr>
<td>2</td>
<td>ABC Corporation</td>
<td>234 Elaine Rd.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>XYZ Corporation</td>
<td>567 Barbara Rd.</td>
<td></td>
</tr>
</tbody>
</table>

Alphabetical list of DataWindow expression functions

The list of DataWindow expression functions follows in alphabetical order.
Abs

Description
Calculates the absolute value of a number.

Syntax
Abs ( n )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number for which you want the absolute value</td>
</tr>
</tbody>
</table>

Return value
The datatype of n. Returns the absolute value of n.

Examples
This expression counts all the product numbers where the absolute value of the product number is distinct:

\[
\text{Count (product_number for All DISTINCT Abs (product_number))}
\]

Only data with an absolute value greater than 5 passes this validation rule:

\[
\text{Abs (value_set) > 5}
\]

See also
Count
Abs in the PowerScript Reference

ACos

Description
Calculates the arc cosine of an angle.

Syntax
ACos ( n )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The ratio of the lengths of two sides of a triangle for which you want a corresponding angle (in radians). The ratio must be a value between -1 and 1.</td>
</tr>
</tbody>
</table>

Return value
Double. Returns the arc cosine of n if it succeeds.

Examples
This expression returns 0:

\[
\text{ACos (1)}
\]

This expression returns 3.141593 (rounded to six places):

\[
\text{ACos (-1)}
\]

This expression returns 1.000000 (rounded to six places):

\[
\text{ACos (.540302)}
\]
See also

Cos
ASin
ATan
ACos in the *PowerScript Reference*

**Asc**

**Description**
Converts the first character of a string to its Unicode code point. A Unicode code point is the numerical integer value given to a Unicode character.

**Syntax**

```
Asc ( string )
```

**Argument** | **Description**
--- | ---
string | The string for which you want the code point value of the first character

**Return value**
Unsigned integer. Returns the code point value of the first character in *string*.

**Usage**
Use *Asc* to test the case of a character or manipulate text and letters.

To find out the case of a character, you can check whether its code point value is within the appropriate range.

**Examples**
This expression for a computed field returns the string in *code_id* if the code point value of the first character in *code_id* is A (65):

```
If (Asc(code_id) = 65, code_id, "Not a valid code")
```

This expression for a computed field checks the case of the first character of *lname* and if it is lowercase, makes it uppercase:

```
IF (Asc(lname) > 64 AND Asc(lname) < 91, lname, WordCap(lname))
```

**See also**
Char
WordCap
Asc in the *PowerScript Reference*
**AscA**

**Description**
Converts the first character of a string to its ASCII integer value.

**Syntax**
```
AscA ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string for which you want the ASCII value of the first character</td>
</tr>
</tbody>
</table>

**Return value**
Integer. Returns the ASCII value of the first character in `string`.

**Usage**
Use `AscA` to test the case of a character or manipulate text and letters.

To find out the case of a character, you can check whether its ASCII value is within the appropriate range.

**Examples**
This expression for a computed field returns the string in `code_id` if the ASCII value of the first character in `code_id` is A (65):
```
If (AscA(code_id) = 65, code_id, "Not a valid code")
```

This expression for a computed field checks the case of the first character of `lname` and if it is lowercase, makes it uppercase:
```
IF (AscA(lname) > 64 AND AscA(lname) < 91, lname, WordCap(lname))
```

**See also**
CharA

WordCap

`AscA` in the *PowerScript Reference*

---

**ASin**

**Description**
Calculates the arc sine of an angle.

**Syntax**
```
ASin ( n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The ratio of the lengths of two sides of a triangle for which you want a corresponding angle (in radians). The ratio must be a value between -1 and 1.</td>
</tr>
</tbody>
</table>

**Return value**
Double. Returns the arc sine of `n` if it succeeds.
Examples

This expression returns 0.999998 (rounded to six places):
\[
\text{ASin}(0.84147)
\]
This expression returns 0.520311 (rounded to six places):
\[
\text{ASin}(\text{LogTen}(\text{Pi}(1)))
\]
This expression returns 0:
\[
\text{ASin}(0)
\]

ASin in the PowerScript Reference

ATan

Description
Calculates the arc tangent of an angle.

Syntax
\[
\text{ATan}(n)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(n)</td>
<td>The ratio of the lengths of two sides of a triangle for which you want a corresponding angle (in radians)</td>
</tr>
</tbody>
</table>

Return value
Double. Returns the arc tangent of \(n\) if it succeeds.

Examples
This expression returns 0:
\[
\text{ATan}(0)
\]
This expression returns 1.000 (rounded to three places):
\[
\text{ATan}(1.55741)
\]
This expression returns 1.267267 (rounded to six places):
\[
\text{ATan}(\text{Pi}(1))
\]

Tan
ASin
ACos
ATan in the PowerScript Reference
Avg

Description
Calculates the average of the values of the column.

Syntax
```
Avg ( column { FOR range { DISTINCT { expres1 , expres2 { , ... } } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want the average of the data values. <code>Column</code> can be the column name or the column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
<tr>
<td><code>FOR range</code></td>
<td>The data that will be included in the average. For most presentation styles, values for <code>range</code> are:</td>
</tr>
<tr>
<td></td>
<td>• ALL – (Default) The average of all values in <code>column</code>.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The average of values in <code>column</code> in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The average of the values in <code>column</code> on a page. For Crosstabs, specify CROSSTAB for <code>range</code>:</td>
</tr>
<tr>
<td></td>
<td>• CROSSTAB – (Crosstabs only) The average of all values in <code>column</code> in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph and OLE objects, specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>• GRAPH – (Graphs only) The average of values in <code>column</code> in the range specified for the Rows option.</td>
</tr>
<tr>
<td></td>
<td>• OBJECT – (OLE objects only) The average of values in <code>column</code> in the range specified for the Rows option.</td>
</tr>
<tr>
<td><code>DISTINCT</code></td>
<td>Causes <code>Avg</code> to consider only the distinct values in <code>column</code> when calculating the average. For a value of <code>column</code>, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td><code>expresn</code></td>
<td>One or more expressions that you want to evaluate to determine distinct rows. <code>Expresn</code> can be the name of a column, a function, or an expression.</td>
</tr>
</tbody>
</table>

Return value
The numeric datatype of the column. Returns the average of the values of the rows in `range`.

Usage
If you specify `range`, `Avg` returns the average value of `column` in `range`. If you specify `DISTINCT`, `Avg` returns the average value of the distinct values in `column`, or if you specify `expresn`, the average of `column` for each distinct value of `expresn`. 
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

In calculating the average, null values are ignored.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**

This expression returns the average of the values in the column named salary:

\[
\text{Avg}(\text{salary})
\]

This expression returns the average of the values in group 1 in the column named salary:

\[
\text{Avg}(\text{salary for group 1})
\]

This expression returns the average of the values in column 5 on the current page:

\[
\text{Avg}(\#5 \text{ for page})
\]

This computed field returns Above Average if the average salary for the page is greater than the average salary:

\[
\text{If}(\text{Avg}(\text{salary for page}) > \text{Avg}(\text{salary}), \text{"Above Average"}, \text{""})
\]

This expression for a graph value sets the data to the average value of the sale_price column:

\[
\text{Avg}(\text{sale_price})
\]

This expression for a graph value sets the data value to the average value of the sale_price column for the entire graph:

\[
\text{Avg}(\text{sale_price for graph})
\]
Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the average of the order amount for the distinct order numbers:

\[ \text{Avg(order amt for all DISTINCT order_nbr)} \]

### Bitmap

**Description**
Displays the specified bitmap.

**For computed fields only**
You can use the `Bitmap` function only in a computed field.

**Syntax**

```
Bitmap ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>string</code></td>
<td>A column containing bitmap files, a string containing the name of an image file (a BMP, GIF, JPEG, RLE, or WMF file), or an expression that evaluates to a string containing the name of an image file</td>
</tr>
</tbody>
</table>

**Return value**
The special datatype bitmap, which cannot be used in any other function.

**Usage**
Use `Bitmap` to dynamically display a bitmap in a computed field. When `string` is a column containing bitmap files, a different bitmap can display for each row.

**Examples**
These examples are all expressions for a computed field.

This expression dynamically displays the bitmap file contained in the column named `employees`:

```
Bitmap (employees)
```

If the `employees` column is column 3, this next expression gives the same result as the expression above:

```
Bitmap (#3)
```

This expression displays the bitmap `tools.bmp`:

```
Bitmap ("TOOLS.BMP")
```
This expression tests the value in the column named password and then uses the value to determine which bitmap to display:

```
Bitmap(If(password = "y", "yes.bmp", "no.bmp")
```

See also “Example 3: creating a row indicator” on page 24

## Case

**Description**
Tests the values of a column or expression and returns values based on the results of the test.

**Syntax**

```
Case ( column WHEN value1 THEN result1 ( WHEN value2 THEN result2 { WHEN ... } } { ELSE resultelse } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>column</strong></td>
<td>The column or expression whose values you want to test. <em>Column</em> can be the column name or the column number preceded by a pound sign (#). <em>Column</em> can also be an expression that includes a reference to the column. <em>Column</em> is compared to each <em>valuen</em>.</td>
</tr>
<tr>
<td><strong>WHEN</strong> (optional)</td>
<td>Introduces a value-result pair. At least one WHEN is required.</td>
</tr>
</tbody>
</table>
| **valuen** | One or more values that you want to compare to values of *column*. A value can be:
  * A single value
  * A list of values separated by commas (for example, 2, 4, 6, 8)
  * A TO clause (for example, 1 TO 20)
  * IS followed by a relational operator and comparison value (for example, IS>5)
  * Any combination of the above with an implied OR between expressions (for example, 1,3,5,7,9,27 TO 33, IS>42) |
| **THEN** | Introduces the result to be returned when *column* matches the corresponding *valuen*. |
| **resultn** | An expression whose value is returned by Case for the corresponding *valuen*. All *resultn* values must have the same datatype. |
| **ELSE** (optional) | Specifies that for any values of *column* that do not match the values of *valuen* already specified, Case returns *resultelse*. |
| **resultelse** | An expression whose value is returned by Case when the value of *column* does not match any WHEN *valuen* expression. |
Ceiling

Description
Retrieves the smallest whole number that is greater than or equal to a specified limit.

Syntax
Ceiling( n )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number for which you want the smallest whole number that is greater than or equal to it</td>
</tr>
</tbody>
</table>

Return value
The datatype of n. Returns the smallest whole number that is greater than or equal to n.

Examples
These expressions both return -4:

Ceiling(-4.2)

Ceiling(-4.8)

See also
“Example 3: creating a row indicator” on page 24

Usage
If more than one WHEN clause matches column, Case returns the result of the first matching one.

Examples
This expression for the Background.Color property of a Salary column returns values that represent red when an employee’s salary is greater than $70,000, green when an employee’s salary is greater than $50,000, and blue otherwise:

Case( salary WHEN IS >70000 THEN RGB(255,0,0) WHEN IS >50000 THEN RGB(0,255,0) ELSE RGB(0,0,255) )

This expression for the Background.Color property of an employee Id column returns red for Id 101, gray for Id 102, and black for all other Id numbers:

Case( emp_id WHEN 101 THEN 255 WHEN 102 THEN RGB(100,100,100) ELSE 0 )

This expression for the Format property of the Marital_status column returns Single, Married, and Unknown based on the data value of the Marital_status column for an employee:

Case( marital_status WHEN 'S' THEN 'Single' WHEN 'M' THEN 'Married' ELSE 'Unknown' )

Return value
The datatype of resultn. Returns the result you specify in resultn.

Usage
If more than one WHEN clause matches column, Case returns the result of the first matching one.

Examples
This expression for the Background.Color property of a Salary column returns values that represent red when an employee’s salary is greater than $70,000, green when an employee’s salary is greater than $50,000, and blue otherwise:

Case( salary WHEN IS >70000 THEN RGB(255,0,0) WHEN IS >50000 THEN RGB(0,255,0) ELSE RGB(0,0,255) )

This expression for the Background.Color property of an employee Id column returns red for Id 101, gray for Id 102, and black for all other Id numbers:

Case( emp_id WHEN 101 THEN 255 WHEN 102 THEN RGB(100,100,100) ELSE 0 )

This expression for the Format property of the Marital_status column returns Single, Married, and Unknown based on the data value of the Marital_status column for an employee:

Case( marital_status WHEN 'S' THEN 'Single' WHEN 'M' THEN 'Married' ELSE 'Unknown' )

See also
“Example 3: creating a row indicator” on page 24

If
This expression for a computed field returns ERROR if the value in discount_amt is greater than the smallest whole number that is greater than or equal to discount_factor times price. Otherwise, it returns discount_amt:

\[
\text{If}(\text{discount\_amt} \leq \text{Ceiling}(\text{discount\_factor} \times \text{price}), \text{String}(\text{discount\_amt}), \text{"ERROR"})
\]

To pass this validation rule, the value in discount_amt must be less than or equal to the smallest whole number that is greater than or equal to discount_factor times price:

\[
\text{discount\_amt} \leq \text{Ceiling}(\text{discount\_factor} \times \text{price})
\]

Int
Round
Truncate
Ceiling in the *PowerScript Reference*

---

### Char

**Description**

Converts an integer to a Unicode character.

**Syntax**

\[
\text{Char}(n)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The integer you want to convert to a character</td>
</tr>
</tbody>
</table>

**Return value**

String. Returns the character whose code point value is \( n \).

**Examples**

This expression returns the escape character:

\[
\text{Char}(27)
\]

See also

Asc
Char in the *PowerScript Reference*
CharA

Description
Converts an integer to an ASCII character.

Syntax
CharA ( n )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The integer you want to convert to a character</td>
</tr>
</tbody>
</table>

Return value
String. Returns the character whose ASCII value is \( n \).

Examples
This expression returns the escape character:
CharA (27)

See also
AscA
CharA in the PowerScript Reference

Cos

Description
Calculates the cosine of an angle.

Syntax
Cos ( n )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The angle (in radians) for which you want the cosine</td>
</tr>
</tbody>
</table>

Return value
Double. Returns the cosine of \( n \).

Examples
This expression returns 1:

\[
\text{Cos} (0)
\]

This expression returns .540302:

\[
\text{Cos} (1)
\]

This expression returns -1:

\[
\text{Cos} (\pi (1))
\]

See also
Pi
Sin
Tan
Cos in the PowerScript Reference
Count

Calculates the total number of rows in the specified column.

**Syntax**

\[
\text{Count} \left( \text{column} \left\{ \text{FOR} \text{range} \left\{ \text{DISTINCT} \left\{ \text{expres}1, \text{expres}2, \ldots \right\} \right\} \right\} \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want the number of rows. Column can be the column name or the column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column.</td>
</tr>
</tbody>
</table>
| `range` (optional) | The data that will be included in the count. For most presentation styles, values for `range` are:  
  - ALL – (Default) The count of all rows in `column`.  
  - GROUP `n` – The count of rows in `column` in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.  
  - PAGE – The count of the rows in `column` on a page.  
  For Crosstabs, specify CROSSTAB for `range`:  
  - CROSSTAB – (Crosstabs only) The count of all rows in `column` in the crosstab.  
  For Graph and OLE objects, specify one of the following:  
  - GRAPH – (Graphs only) The count of values in `column` in the range specified for the Rows option.  
  - OBJECT – (OLE objects only) The count of values in `column` in the range specified for the Rows option. |
| `DISTINCT` (optional) | Causes Count to consider only the distinct values in `column` when counting the rows. For a value of `column`, the first row found with the value is used and other rows that have the same value are ignored. |
| `expres` (optional) | One or more expressions that you want to evaluate to determine distinct rows. `Expres` can be the name of a column, a function, or an expression. |

**Usage**

If you specify `range`, Count determines the number of rows in `column` in `range`. If you specify `DISTINCT`, Count returns the number of the distinct rows displayed in `column`, or if you specify `expres`, the number of rows displayed in `column` where the value of `expres` is distinct.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range.
Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Null values in the column are ignored and are not included in the count.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**

This expression returns the number of rows in the column named emp_id that are not null:

```
Count(emp_id)
```

This expression returns the number of rows in the column named emp_id of group 1 that are not null:

```
Count(emp_id for group 1)
```

This expression returns the number of dept_ids that are distinct:

```
Count(dept_id for all DISTINCT)
```

This expression returns the number of regions with distinct products:

```
Count(region_id for all DISTINCT Lower(product_id))
```

This expression returns the number of rows in column 3 on the page that are not null:

```
Count(#3 for page)
```

**See also**

“Example 1: counting null values in a column” on page 19
CrosstabAvg

Calculates the average of the values returned by an expression in the values list of the crosstab. When the crosstab definition has more than one column, CrosstabAvg can also calculate averages of the expression’s values for groups of column values.

For crosstabs only
You can use this function only in a crosstab DataWindow object.

Syntax

CrosstabAvg ( n {, column, groupvalue } )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number of the crosstab-values expression for which you want the average of the returned values. The crosstab expression must be numeric.</td>
</tr>
<tr>
<td>column (optional)</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>groupvalue (optional)</td>
<td>A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value
Double. Returns the average of the crosstab values returned by expression n for all the column values or, optionally, for a subset of column values. To return a decimal datatype, use CrosstabAvgDec.

Usage
This function is meaningful only for the average of the values of the expression in a row in the crosstab. This means you can use it only in the detail band, not in a header, trailer, or summary band.

Null values are ignored and are not included in the average.

How functions in a crosstab are used
When a crosstab is generated from your definition, the appropriate computed fields are automatically created using the Crosstab functions. To understand the functions, consider a crosstab with two columns (year and quarter), a row (product), and the values expression Avg(amount for crosstab).
The Crosstab Definition dialog box looks like this.

When you define the crosstab described above, the painter automatically creates the appropriate computed fields. A computed field named `avg_amount` returns the average of the quarterly figures for each year. Its expression is:

```
CrosstabAvg(1, 2, "@year")
```

A second computed field named `grand_avg_amount` computes the average of all the amounts in the row. Its expression is:

```
CrosstabAvg(1)
```

Other computed fields in the summary band use the `Avg` function to display the average of the values in the amount column, the yearly averages, and the final average.

The crosstab in the Design view looks like this.
Each row in the crosstab (after adjusting the column widths) has cells for the amounts in the quarters, a repeating cell for the yearly average, and a grand average. The crosstab also displays averages of the amounts for all the financial codes in the quarters in the summary band at the bottom.

What the function arguments mean When the crosstab definition has more than one column, you can specify column qualifiers for any of the Crosstab functions, so that the crosstab displays calculations for groups of column values. As illustrated previously, when year and quarter are the columns in the crosstab, the expression for the computed field is:

\[ \text{CrosstabAvg}(1, 2, "@year") \]

The value 2 refers to the quarter column (the second column in the Crosstab Definition dialog) and "@year" specifies grouping values from the year column (meaning the function will average values for the quarters within each year). The value 1 refers to the crosstab-values expression that will be averaged. In the resulting crosstab, the computed field repeats in each row after the cells for the quarters within each year.

Tips for defining crosstabs When you define a crosstab with more than one column, the order of the columns in the Columns box of the Crosstab Definition dialog box governs the way the columns are grouped. To end up with the most effective expressions, make the column that contains the grouping values (for example, year or department) the first column in the Columns box and the column that contains the values to be grouped (for example, quarter or employee) second.
To display calculations for groups of rows, define groups as you would for other DataWindow presentation styles and define computed fields in the group header or footer using noncrosstab aggregation functions, such as \texttt{Avg}, \texttt{Sum}, or \texttt{Max}.

**Reviewing the expressions**

To review the expressions defined for the crosstab values, open the Crosstab Definition dialog box (select Design>Crosstab from the menubar).

**Examples**

The first two examples use the crosstab expressions shown below:

\[
\text{Count(emp\_id for crosstab), Sum(salary for crosstab)}
\]

This expression for a computed field in the crosstab returns the average of the employee counts (the first expression):

\texttt{CrosstabAvg(1)}

This expression for a computed field in the crosstab returns the average of the salary totals (the second expression):

\texttt{CrosstabAvg(2)}

Consider a crosstab that has two columns (region and city) and the values expression \texttt{Avg(sales for crosstab)}. This expression for a computed field in the detail band computes the average sales over all the cities in a region:

\texttt{CrosstabAvg(1, 2, "@region")}

This expression for another computed field in the same crosstab computes the grand average over all the cities:

\texttt{CrosstabAvg(1)}

**See also**

\texttt{CrosstabAvgDec}
\texttt{CrosstabCount}
\texttt{CrosstabMax}
\texttt{CrosstabMin}
\texttt{CrosstabSum}
### CrosstabAvgDec

**Description**
Calculates the average of the values returned by an expression in the values list of the crosstab and returns a result with the decimal datatype. When the crosstab definition has more than one column, CrosstabAvgDec can also calculate averages of the expression’s values for groups of column values.

**For crosstabs only**
You can use this function *only* in a crosstab DataWindow object.

**Syntax**
```crosstabavgdec ( n {, column, groupvalue } )```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number of the crosstab-values expression for which you want the average of the returned values. The crosstab expression must be numeric.</td>
</tr>
<tr>
<td>column</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>groupvalue</td>
<td>A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

**Return value**
Decimal. Returns the average of the crosstab values returned by expression \( n \) for all the column values or, optionally, for a subset of column values.

**Usage**
Use this function instead of CrosstabAvg when you want to return a decimal datatype instead of a double datatype. For more information, see CrosstabAvg.

**See also**
- CrosstabMaxDec
- CrosstabMinDec
- CrosstabSumDec
CrosstabCount

Description
Counts the number of values returned by an expression in the values list of the crosstab. When the crosstab definition has more than one column, CrosstabCount can also count the number of the expression’s values for groups of column values.

For crosstabs only
You can use this function only in a crosstab DataWindow object.

Syntax
CrosstabCount ( n {, column, groupvalue } )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number of the crosstab-values expression for which you want the total number of returned values.</td>
</tr>
<tr>
<td>column</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog for which you want intermediate calculations.</td>
</tr>
<tr>
<td>groupvalue</td>
<td>A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value
Long. Returns the number of values returned by expression n for all the column values or, optionally, for a subset of column values.

Usage
This function is meaningful only for the count of the values of the expression in a row in the crosstab. This means you can use it only in the detail band, not in a header, trailer, or summary band.

Null values are ignored and are not included in the count.

For more information about restricting the calculation to groups of values when the crosstab definition has more than one column, see Usage for CrosstabAvg.

Reviewing the expressions
To review the expressions defined for the crosstab values, open the Crosstab Definition dialog box (select Design>Crosstab from the menubar).

Examples
These examples all use the crosstab-values expressions shown below:

  Count(emp_id for crosstab), Sum(salary for crosstab)
This expression for a computed field in the crosstab returns the count of the employee counts (the first expression):

\texttt{CrosstabCount(1)}

This expression for a computed field in the crosstab returns the count of the salary totals (the second expression):

\texttt{CrosstabCount(2)}

The next two examples use a crosstab with two columns (year and quarter), a row (product), and the values expression \texttt{Avg(sales for crosstab)}.

This expression for a computed field returns the count of the sales for each year:

\texttt{CrosstabCount(1, 2, "@year")}

This expression for a computed field returns the count of all the sales in the row:

\texttt{CrosstabCount(1)}

For an example illustrating how the painter automatically defines a crosstab by creating computed fields using the Crosstab functions, see \texttt{CrosstabAvg}.

\textbf{See also}

\texttt{CrosstabAvg}  
\texttt{CrosstabMax}  
\texttt{CrosstabMin}  
\texttt{CrosstabSum}

\section*{CrosstabMax}

\textbf{Description}

Calculates the maximum value returned by an expression in the values list of the crosstab. When the crosstab definition has more than one column, \texttt{CrosstabMax} can also calculate the maximum of the expression’s values for groups of column values.

\textbf{For crosstabs only}

You can use this function \textit{only} in a crosstab DataWindow object.
**CrosstabMax**

Syntax

```
CrosstabMax( n {, column, groupvalue } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n</code></td>
<td>The number of the crosstab-values expression for which you want the maximum returned value. The expression’s datatype must be numeric.</td>
</tr>
<tr>
<td><code>column</code> (optional)</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td><code>groupvalue</code> (optional)</td>
<td>A string whose value controls the grouping for the calculation. <code>Groupvalue</code> is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value

Double. Returns the maximum value returned by expression `n` for all the column values or, optionally, for a subset of column values. To return a decimal datatype, use `CrosstabMaxDec`.

Usage

This function is meaningful *only* for the maximum of the values of the expression in a row in the crosstab. This means you can use it only in the detail band, not in a header, trailer, or summary band.

Null values are ignored and are not included in the comparison.

For more information about restricting the calculation to groups of values when the crosstab definition has more than one column, see Usage for `CrosstabAvg`.

Reviewing the expressions

To review the expressions defined for the crosstab values, open the Crosstab Definition dialog box (select Design>Crosstab from the menubar).

Examples

These examples all use the crosstab-values expressions shown below:

```
Count(emp_id for crosstab),Sum(salary for crosstab)
```

This expression for a computed field in the crosstab returns the maximum of the employee counts (the first expression):

```
CrosstabMax(1)
```

This expression for a computed field in the crosstab returns the maximum of the salary totals (the second expression):

```
CrosstabMax(2)
```

The next two examples use a crosstab with two columns (year and quarter), a row (product), and a values expression `Avg(sales for crosstab)`. 
CHAPTER 2  DataWindow Expression Functions

This expression for a computed field returns the largest of the quarterly average sales for each year:

\[
\text{CrosstabMax}(1, 2, "@year")
\]

This expression for a computed field returns the maximum of all the average sales in the row:

\[
\text{CrosstabMax}(1)
\]

For an example illustrating how the painter automatically defines a crosstab by creating computed fields using the Crosstab functions, see CrosstabAvg.

CrosstabMaxDec

Description
Calculates the maximum value returned by an expression in the values list of the crosstab and returns a result with the decimal datatype. When the crosstab definition has more than one column, CrosstabMaxDec can also calculate the maximum of the expression’s values for groups of column values.

Syntax
\[
\text{CrosstabMaxDec}(n \{, column, groupvalue \})
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The number of the crosstab-values expression for which you want the maximum returned value. The expression’s datatype must be numeric.</td>
</tr>
<tr>
<td>( column )</td>
<td>(optional) The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>( groupvalue )</td>
<td>(optional) A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>
CrosstabMin

Return value

Decimal. Returns the maximum value returned by expression \( n \) for all the column values or, optionally, for a subset of column values.

Usage

Use this function instead of CrosstabMax when you want to return a decimal datatype instead of a double datatype. For more information, see CrosstabMax.

See also

CrosstabAvgDec
CrosstabMinDec
CrosstabSumDec

CrosstabMin

Description

Calculates the minimum value returned by an expression in the values list of the crosstab. When the crosstab definition has more than one column, CrosstabMin can also calculate the minimum of the expression’s values for groups of column values.

For crosstabs only

You can use this function only in a crosstab DataWindow object.

Syntax

\[
\text{CrosstabMin} \left( n \{, \, \text{column}, \, \text{groupvalue} \} \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The number of the crosstab-values expression for which you want the minimum return value. The expression’s datatype must be numeric.</td>
</tr>
<tr>
<td>( \text{column} ) (optional)</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>( \text{groupvalue} ) (optional)</td>
<td>A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value

Double. Returns the minimum value returned by expression \( n \) for all the column values or, optionally, for a subset of column values. To return a decimal datatype, use CrosstabMinDec.

Usage

This function is meaningful only for the minimum of the values of the expression in a row in the crosstab. This means you can use it only in the detail band, not in a header, trailer, or summary band.
Null values are ignored and are not included in the comparison.
For more information about restricting the calculation to groups of values when the crosstab definition has more than one column, see Usage for CrosstabAvg.

**Examples**
These examples all use the crosstab-values expressions shown below:

\[ \text{Count(emp_id for crosstab)}, \text{Sum(salary for crosstab)} \]

This expression for a computed field in the crosstab returns the minimum of the employee counts (the first expression):

\[ \text{CrosstabMin}(1) \]

This expression for a computed field in the crosstab returns the minimum of the salary totals (the second expression):

\[ \text{CrosstabMin}(2) \]

The next two examples use a crosstab with two columns (year and quarter), a row (product), and the values expression \( \text{Avg(sales for crosstab)} \).

This expression for a computed field returns the smallest of the quarterly average sales for each year:

\[ \text{CrosstabMin}(1, 2, "@year") \]

This expression for a computed field returns the minimum of all the average sales in the row:

\[ \text{CrosstabMin}(1) \]

For an example illustrating how the painter automatically defines a crosstab by creating computed fields using the crosstab functions, see CrosstabAvg.

CrosstabMinDec

Description
Calculates the minimum value returned by an expression in the values list of the crosstab and returns a result with the decimal datatype. When the crosstab definition has more than one column, CrosstabMinDec can also calculate the minimum of the expression’s values for groups of column values.

For crosstabs only
You can use this function only in a crosstab DataWindow object.

Syntax
CrosstabMinDec ( n {, column, groupvalue } )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number of the crosstab-values expression for which you want the minimum return value. The expression’s datatype must be numeric.</td>
</tr>
<tr>
<td>column (optional)</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>groupvalue (optional)</td>
<td>A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value
Decimal. Returns the minimum value returned by expression n for all the column values or, optionally, for a subset of column values.

Usage
Use this function instead of CrosstabMin when you want to return a decimal datatype instead of a double datatype. For more information, see CrosstabMin.

See also
CrosstabAvgDec
CrosstabMaxDec
CrosstabSumDec
CrosstabSum

Description
Calculates the sum of the values returned by an expression in the values list of the crosstab. When the crosstab definition has more than one column, CrosstabSum can also calculate the sum of the expression’s values for groups of column values.

For crosstabs only
You can use this function only in a crosstab DataWindow object.

Syntax
CrosstabSum ( n, column, groupvalue )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number of the crosstab-values expression for which you want the sum of the returned values. The expression’s datatype must be numeric.</td>
</tr>
<tr>
<td>column</td>
<td>(optional) The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>groupvalue</td>
<td>(optional) A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value
Double. Returns the total of the values returned by expression n for all the column values or, optionally, for a subset of column values. To return a decimal datatype, use CrosstabSumDec.

Usage
This function is meaningful only for the sum of the values of the expression in a row in the crosstab. This means you can use it only in the detail band, not in a header, trailer, or summary band.

Null values are ignored and are not included in the sum.

For more information about restricting the calculation to groups of values when the crosstab definition has more than one column, see Usage for CrosstabAvg.

Reviewing the expressions
To review the expressions defined for the crosstab values, open the Crosstab Definition dialog box (select Design>Crosstab from the menubar).
These examples all use the crosstab-values expressions shown below:

```
Count(emp_id for crosstab), Sum(salary for crosstab)
```

This expression for a computed field in the crosstab returns the sum of the employee counts (the first expression):

```
CrosstabSum(1)
```

This expression for a computed field in the crosstab returns the sum of the salary totals (the second expression):

```
CrosstabSum(2)
```

The next two examples use a crosstab with two columns (year and quarter), a row (product), and the values expression Avg(sales for crosstab).

This expression for a computed field returns the sum of the quarterly average sales for each year:

```
CrosstabSum(1, 2, "@year")
```

This expression for a computed field returns the sum of all the average sales in the row:

```
CrosstabSum(1)
```

For an example illustrating how the painter automatically defines a crosstab by creating computed fields using the Crosstab functions, see CrosstabAvg.

CrosstabMin  
CrosstabSumDec

---

**CrosstabSumDec**  

**Description**  
Calculates the sum of the values returned by an expression in the values list of the crosstab and returns a result with the decimal datatype. When the crosstab definition has more than one column, CrosstabSumDec can also calculate the sum of the expression’s values for groups of column values.

**For crosstabs only**  
You can use this function *only* in a crosstab DataWindow object.
CHAPTER 2  DataWindow Expression Functions

Syntax

\[
\text{CrosstabSumDec} \left( n, \{column, groupvalue\} \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(n)</td>
<td>The number of the crosstab-values expression for which you want the sum of the returned values. The expression’s datatype must be numeric.</td>
</tr>
<tr>
<td>(column)</td>
<td>The number of the crosstab column as it is listed in the Columns box of the Crosstab Definition dialog box for which you want intermediate calculations.</td>
</tr>
<tr>
<td>(groupvalue)</td>
<td>A string whose value controls the grouping for the calculation. Groupvalue is usually a value from another column in the crosstab. To specify the current column value in a dynamic crosstab, rather than a specific value, specify @ plus the column name as a quoted string.</td>
</tr>
</tbody>
</table>

Return value

Decimal. Returns the total of the values returned by expression \(n\) for all the column values or, optionally, for a subset of column values.

Usage

Use this function instead of CrosstabSum when you want to return a decimal datatype instead of a double datatype. For more information, see CrosstabSum.

See also

CrosstabAvgDec
CrosstabMaxDec
CrosstabMinDec

CumulativePercent

Description

Calculates the total value of the rows up to and including the current row in the specified column as a percentage of the total value of the column (a running percentage).

Syntax

\[
\text{CumulativePercent} \left( column \{FOR range\} \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(column)</td>
<td>The column for which you want the cumulative value of the rows up to and including the current row as a percentage of the total value of the column for range. Column can be the column name or the column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. The datatype of column must be numeric.</td>
</tr>
</tbody>
</table>
**CumulativePercent**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR range (optional)</td>
<td>The data that will be included in the cumulative percentage. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td></td>
<td>• ALL – (Default) The cumulative percentage of all rows in <em>column</em>.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The cumulative percentage of rows in <em>column</em> in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The cumulative percentage of the rows in <em>column</em> on a page.</td>
</tr>
<tr>
<td></td>
<td>For Crosstabs, specify CROSSTAB for range:</td>
</tr>
<tr>
<td></td>
<td>• CROSSTAB – (Crosstabs only) The cumulative percentage of all rows in <em>column</em> in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph and OLE objects, specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>• GRAPH – (Graphs only) The cumulative percentage of values in <em>column</em> in the range specified for the Rows option.</td>
</tr>
<tr>
<td></td>
<td>• OBJECT – (OLE objects only) The cumulative percentage of values in <em>column</em> in the range specified for the Rows option.</td>
</tr>
</tbody>
</table>

**Return value**

Long. Returns the cumulative percentage value.

**Usage**

If you specify *range*, CumulativePercent restarts the accumulation at the start of the range.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range.

Settings for Rows include the following:

• For the Graph or OLE presentation style, Rows is always All.
• For Graph controls, Rows can be All, Page, or Group.
• For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

In calculating the percentage, null values are ignored.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.
Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**

This expression returns the running percentage for the values that are not null in the column named salary:

```plaintext
CumulativePercent(salary)
```

This expression returns the running percentage for the column named salary for the values in group 1 that are not null:

```plaintext
CumulativePercent(salary for group 1)
```

This expression entered in the Value box on the Data property page for a graph returns the running percentage for the salary column for the values in the graph that are not null:

```plaintext
CumulativePercent(salary for graph)
```

This expression in a crosstab computed field returns the running percentage for the salary column for the values in the crosstab that are not null:

```plaintext
CumulativePercent(salary for crosstab)
```

**See also**

Percent
CumulativeSum

---

**CumulativeSum**

**Description**
Calculates the total value of the rows up to and including the current row in the specified column (a running total).

**Syntax**

```plaintext
CumulativeSum ( column { FOR range } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| `column`   | The column for which you want the cumulative total value of the rows up to and including the current row for group. `Column` can be
|             | the column name or the column number preceded by a pound sign (#). `Column` can also be an expression that includes a reference to
|             | the column. The datatype of `column` must be numeric. |
## CumulativeSum

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| FOR range (optional) | The data that will be included in the cumulative sum. For most presentation styles, values for range are:  
  - ALL – (Default) The cumulative sum of all values in column.  
  - GROUP n – The cumulative sum of values in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.  
  - PAGE – The cumulative sum of the values in column on a page. For Crosstabs, specify CROSSTAB for range:  
    - CROSSTAB – (Crosstabs only) The cumulative sum of all values in column in the crosstab.  
  - For Graph and OLE objects, specify one of the following:  
    - GRAPH – (Graphs only) The cumulative sum of values in column in the range specified for the Rows option.  
    - OBJECT – (OLE objects only) The cumulative sum of values in column in the range specified for the Rows option. |

### Return value
The appropriate numeric datatype. Returns the cumulative total value of the rows.

### Usage
If you specify range, CumulativeSum restarts the accumulation at the start of the range.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

In calculating the sum, null values are ignored.

### Examples
This expression returns the running total for the values that are not null in the column named salary:

```powershell
CumulativeSum(salary)
```

This expression returns the running total for the values that are not null in the column named salary in group 1:

```powershell
CumulativeSum(salary for group 1)
```
This expression entered in the Value box on the Data property page for a graph returns the running total for the salary column for the values in the graph that are not null:

\[ \text{CumulativeSum(salary for graph)} \]

This expression in a crosstab computed field returns the running total for the salary column for the values in the crosstab that are not null:

\[ \text{CumulativeSum(salary for crosstab)} \]

**CurrentRow**

**Description**

Reports the number of the current row (the row with focus).

**Syntax**

`CurrentRow()`

**Return value**

Long. Returns the number of the row if it succeeds and 0 if no row is current.

**What row is current**

The current row is not always a row displayed on the screen. For example, if the cursor is on row 7 column 2 and the user uses the scroll bar to scroll to row 50, the current row remains row 7 unless the user clicks row 50.

**Examples**

This expression in a computed field returns the number of the current row:

`CurrentRow()`

This expression for a computed control displays an arrow bitmap as an indicator for the row with focus and displays no bitmap for rows not having focus. As the user moves from row to row, an arrow marks where the user is:

`Bitmap(If(CurrentRow() = GetRow(),"arrow.bmp",""))`

Alternatively, this expression for the Visible property of an arrow picture control makes the arrow bitmap visible for the row with focus and invisible for rows not having focus. As the user moves from row to row, an arrow marks where the user is:

`If(CurrentRow() = GetRow(), 1, 0)`

**See also**

“Example 3: creating a row indicator” on page 24

GetRow
Date

Description
Converts a string whose value is a valid date to a value of datatype date.

Syntax
Date ( string )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>A string containing a valid date (such as Jan 1, 2004, or 12-31-99) that you want returned as a date</td>
</tr>
</tbody>
</table>

Return value
Date. Returns the date in string as a date. If string does not contain a valid date, Date returns null.

Regional Settings
To make sure you get correct return values for the year, you must verify that yyyy is the Short Date Style for year in the Regional Settings of the user’s Control Panel. Your program can check this with the RegistryGet function.

If the setting is not correct, you can ask the user to change it manually or to have the application change it (by calling the RegistrySet function). The user might need to reboot after the setting is changed.

Usage
The value of the string must be a valid date.

Valid dates
Valid dates can include any combination of day (1–31), month (1–12 or the name or abbreviation of a month), and year (two or four digits). Leading zeros are optional for month and day. If the month is a name or an abbreviation, it can come before or after the day; if it is a number, it must be in the month location specified in the Windows control panel. A 4-digit number is assumed to be a year.

If the year is two digits, the assumption of century follows this rule: for years between 00 and 49, the first two digits are assumed to be 20; for years between 50 and 99, the first two digits are assumed to be 19. If your data includes dates before 1950, such as birth dates, always specify a four-digit year to ensure the correct interpretation.

The function handles years from 1000 to 3000 inclusive.

An expression has a more limited set of datatypes than the functions that can be part of the expression. Although the Date function returns a date value, the whole expression is promoted to a DateTime value. Therefore, if your expression consists of a single Date function, it will appear that Date returns the wrong datatype. To display the date without the time, choose an appropriate display format. (See “Using DataWindow expression functions” on page 17.)
Examples

These expressions all return the date datatype for July 4, 2004 when the default location of the month in Regional Settings is center:

```plaintext
Date("2004/07/04")
Date("2004 July 4")
Date("July 4, 2004")
```

See also

IsDate
Date in the *PowerScript Reference*

---

**DateTime**

**Description**

 Combines a date and a time value into a DateTime value.

**Syntax**

```plaintext
DateTime ( date {, time } )
```

**Argument** | **Description**
--- | ---
`date` | A valid date (such as Jan 1, 2005, or 12-31-99) or a blob variable whose first value is a date that you want included in the value returned by `DateTime`.

`time` (optional) | A valid time (such as 8am or 10:25:23:456799) or a blob variable whose first value is a time that you want included in the value returned by `DateTime`. If you include a time, only the hour portion is required. If you omit the minutes, seconds, or microseconds, they are assumed to be zeros. If you omit am or pm, the hour is determined according to the 24-hour clock.

**Return value**

DateTime. Returns a DateTime value based on the values in `date` and optionally `time`. If time is omitted, `DateTime` uses 00:00:00.000000 (midnight).

**Usage**

To display microseconds in a time, the display format for the field must include microseconds.

For information on valid dates, see Date.

**Examples**

This expression returns the values in the order_date and order_time columns as a DateTime value that can be used to update the database:

```plaintext
DateTime(Order_Date, Order_Time)
```

Using this expression for a computed field displays 11/11/01 11:11:00:

```plaintext
DateTime(11/11/01, 11:11)
```

See also

Date
Time
DateTime in the *PowerScript Reference*
Day

Description
Obtains the day of the month in a date value.

Syntax

Day (date)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date for which you want the day</td>
</tr>
</tbody>
</table>

Return value
Integer. Returns an integer (1–31) representing the day of the month in date.

Examples
This expression returns 31:

```powerbuilder
Day (2005-01-31)
```

This expression returns the day of the month in the start_date column:

```powerbuilder
Day (start_date)
```

See also
Date
IsDate
Month
Year
Day in the PowerScript Reference

DayName

Description
Gets the day of the week in a date value and returns the weekday’s name.

Syntax

DayName (date)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date for which you want the name of the day</td>
</tr>
</tbody>
</table>

Return value
String. Returns a string whose value is the name of the weekday (Sunday, Monday, and so on) for date.

Usage
DayName returns a name in the language of the deployment files available on the machine where the application is run. If you have installed localized deployment files in the development environment or on a user’s machine, then on that machine the name returned by DayName will be in the language of the localized files.

For information about localized deployment files, see the chapter on internationalizing an application in Application Techniques.
**Examples**

This expression for a computed field returns Okay if the day in `date_signed` is not Sunday:

```plaintext
If(DayName(date_signed) <> "Sunday", "Okay", "Invalid Date")
```

To pass this validation rule, the day in `date_signed` must not be Sunday:

```plaintext
DayName(date_signed) <> "Sunday"
```

**See also**

- Date
- Day
- DayNumber
- IsDate
- DayName in the *PowerScript Reference*

### DayNumber

**Description**

Gets the day of the week of a date value and returns the number of the weekday.

**Syntax**

```plaintext
DayNumber ( date )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date from which you want the number of the day of the week</td>
</tr>
</tbody>
</table>

**Return value**

Integer. Returns an integer (1–7) representing the day of the week of `date`. Sunday is day 1, Monday is day 2, and so on.

**Examples**

This expression for a computed field returns Wrong Day if the date in `start_date` is not a Sunday or a Monday:

```plaintext
If(DayNumber(start_date) > 2, "Okay", "Wrong Day")
```

This expression for a computed field returns Wrong Day if the date in `end_date` is not a Saturday or a Sunday:

```plaintext
If(DayNumber(end_date) > 1 and DayNumber(end_date) < 7, "Okay", "Wrong Day")
```

This validation rule for the column `end_date` ensures that the day is not a Saturday or Sunday:

```plaintext
DayNumber(end_date) >1 and DayNumber(end_date) < 7
```

**See also**

- Date
- Day
- DayName
- IsDate
- DayNumber in the *PowerScript Reference*
DaysAfter

Description
Gets the number of days one date occurs after another.

Syntax

\[
\text{DaysAfter ( date1, date2 )}
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date1</td>
<td>A date value that is the start date of the interval being measured</td>
</tr>
<tr>
<td>date2</td>
<td>A date value that is the end date of the interval</td>
</tr>
</tbody>
</table>

Return value
Long. Returns a long containing the number of days date2 occurs after date1. If date2 occurs before date1, DaysAfter returns a negative number.

Examples
This expression returns 4:

\[
\text{DaysAfter (2005-12-20, 2005-12-24)}
\]

This expression returns –4:

\[
\text{DaysAfter (2005-12-24, 2005-12-20)}
\]

This expression returns 0:

\[
\text{DaysAfter (2005-12-24, 2005-12-24)}
\]

This expression returns 5:

\[
\text{DaysAfter (2004-12-29, 2005-01-03)}
\]

See also
Date
SecondsAfter
DaysAfter in the *PowerScript Reference*

Dec

Description
Converts the value of a string to a decimal.

Syntax

\[
\text{Dec ( string )}
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want returned as a decimal</td>
</tr>
</tbody>
</table>

Return value
Decimal. Returns the contents of string as a decimal if it succeeds and 0 if string is not a number.
Usage
The decimal datatype supports up to 28 digits.
You can also append the letter D in upper or lowercase to identify a number as a decimal constant in DataWindow expressions. For example, 2.0d and 123.456789012345678901D are treated as decimals.

Examples
This expression returns the string 24.3 as a decimal datatype:

\[ \text{Dec}("24.3") \]

This expression for a computed field returns “Not a valid score” if the string in the score column does not contain a number. The expression checks whether the Dec function returns 0, which means it failed to convert the value:

\[ \text{If ( Dec(score) <> 0, score, "Not a valid score")} \]

This expression returns 0:

\[ \text{Dec}("3ABC") \quad // \text{3ABC is not a number} \]

This validation rule checks that the value in the column the user entered is greater than 1999.99:

\[ \text{Dec(GetText())} > 1999.99 \]

This validation rule for the column named score insures that score contains a string:

\[ \text{Dec(score)} <> 0 \]

See also
Dec in the PowerScript Reference

Describe
Description
Reports the values of properties of a DataWindow object and controls within the object. Each column and graphic control in the DataWindow object has a set of properties, which are listed in “Controls in a DataWindow and their properties” on page 155. You specify one or more properties as a string and Describe returns the values of the properties.

Syntax
\[ \text{Describe ( propertylist )} \]
Exp

Description
 Raises e to the specified power.

Syntax
 \texttt{Exp (n)}

Argument | Description
--- | ---
 \texttt{n} | The power to which you want to raise e (2.71828)

Return value
 Double. Returns e raised to the power \textit{n}.

Examples
 This expression returns 7.38905609893065:
 \[ \text{Exp (2)} \]

See also
 Log
 LogTen
 Exp in the \textit{PowerScript Reference}

---

\begin{tabular}{|l|l|}
\hline
\textbf{Argument} & \textbf{Description} \\
\hline
\texttt{propertylist} & A string whose value is a blank-separated list of properties or Evaluate functions. For a list of valid properties, see “Controls in a DataWindow and their properties” on page 155. \\
\hline
\textbf{Return value} & String. Returns a string that includes a value for each property or Evaluate function. A new line character (~n) separates the value of each item in propertylist. \\
 & If propertylist contains an invalid item, Describe returns an exclamation point (!) for that item and ignores the rest of propertylist. Describe returns a question mark (?) if there is no value for a property. \\
\hline
\textbf{Usage} & Specifying the values for propertylist can be complex. For information and examples, see the Describe method for the DataWindow control. \\
\hline
\textbf{Examples} & This expression for a computed field in the header band of a DataWindow object displays the DataWindow object's SELECT statement: \\
 & \texttt{Describe("DataWindow.Table.Select")} \\
\hline
\textbf{See also} & Describe on page 596 \\
\hline
\end{tabular}
**Fact**

Description  
Gets the factorial of a number.

Syntax  
\[ \text{Fact} \left( n \right) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The number for which you want the factorial</td>
</tr>
</tbody>
</table>

Return value  
Double. Returns the factorial of \( n \).

Examples  
This expression returns 24:
\[ \text{Fact} \left( 4 \right) \]

Both these expressions return 1:
\[ \text{Fact} \left( 1 \right) \]
\[ \text{Fact} \left( 0 \right) \]

See also  
Fact in the *PowerScript Reference*

---

**Fill**

Description  
Builds a string of the specified length by repeating the specified characters until the result string is long enough.

Syntax  
\[ \text{Fill} \left( \text{chars}, \ n \right) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{chars}</td>
<td>A string whose value will be repeated to fill the return string</td>
</tr>
<tr>
<td>( n )</td>
<td>A long whose value is the number of characters in the string you want returned</td>
</tr>
</tbody>
</table>

Return value  
String. Returns a string \( n \) characters long filled with repetitions of the characters in the argument \text{chars}. If the argument \text{chars} has more than \( n \) characters, the first \( n \) characters of \text{chars} are used to fill the return string. If the argument \text{chars} has fewer than \( n \) characters, the characters in \text{chars} are repeated until the return string has \( n \) characters.

Usage  
Fill is used to create a line or other special effect. For example, asterisks repeated in a printed report can fill an amount line, or hyphens can simulate a total line in a screen display.

Examples  
This expression returns a string containing 35 asterisks:
\[ \text{Fill} \left( \text{"*"}, \ 35 \right) \]
This expression returns the string "++--":

```
Fill("++--", 7)
```

This expression returns 10 tildes (~):

```
Fill("~", 10)
```

See also

FillA
Space
Fill in the PowerScript Reference

---

**FillA**

**Description**

Builds a string of the specified length in bytes by repeating the specified characters until the result string is long enough.

**Syntax**

```
FillA ( chars, n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chars</td>
<td>A string whose value will be repeated to fill the return string</td>
</tr>
<tr>
<td>n</td>
<td>A long whose value is the number of bytes in the string you want returned</td>
</tr>
</tbody>
</table>

**Return value**

String. Returns a string \( n \) bytes long filled with repetitions of the characters in the argument `chars`. If the argument `chars` has more than \( n \) bytes, the first \( n \) bytes of `chars` are used to fill the return string. If the argument `chars` has fewer than \( n \) bytes, the characters in `chars` are repeated until the return string has \( n \) bytes.

**Usage**

FillA replaces the functionality that Fill had in DBCS environments in PowerBuilder 9. In SBCS environments, Fill and FillA return the same results.

**See also**

Fill
FillA in the PowerScript Reference
**First**

Reports the value in the first row in the specified column.

**Syntax**

\[
\text{First ( column \{ FOR range \{ DISTINCT \{ expresn \{, expres2 \{, \ldots \}\}\}\}\) } \]

**Argument | Description**

| column    | The column for which you want the value of the first row. Column can be a column name or a column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. |
| FOR range (optional) | The data that will be included when the value in the first row is found. Values for range depend on the presentation style. See the Usage section for more information. |
| DISTINCT (optional) | Causes First to consider only the distinct values in column when determining the first value. For a value of column, the first row found with the value is used and other rows that have the same value are ignored. |
| expresn (optional) | One or more expressions that you want to evaluate to determine distinct rows. Expresn can be the name of a column, a function, or an expression. |

**Return value**

The datatype of the column. Returns the value in the first row of column. If you specify range, First returns the value of the first row in column in range.

**Usage**

If you specify range, First determines the value of the first row in column in range. If you specify DISTINCT, First returns the first distinct value in column, or if you specify expresn, the first distinct value in column where the value of expresn is distinct.

For most presentation styles, values for range are:

- **ALL** – (Default) The value in the first of all rows in column.
- **GROUP n** – The value in the first of rows in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.
- **PAGE** – The value in the first of the rows in column on a page.

For Crosstabs, specify CROSSTAB for range to indicate the first of all rows in column in the crosstab.

For Graphs specify GRAPH and for OLE objects specify OBJECT for range, to indicate the value in the first row in column in the range specified for the Rows option.
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

**Not in validation rules or filter expressions**
You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**
This expression returns the first value in column 3 on the page:

```
First(#3 for page)
```

This expression returns the first distinct value in the column named dept_id in group 2:

```
First(dept_id for group 2 DISTINCT)
```

This expression returns the first value in the column named dept_id in group 2:

```
First(dept_id for group 2)
```

**See also**
Last
GetRow

Description
Reports the number of a row associated with a band in a DataWindow object.

Syntax
GetRow ( )

Return value
Long. Returns the number of a row if it succeeds, 0 if no data has been retrieved or added, and -1 if an error occurs. Where you call GetRow determines what row it returns, as follows:

<table>
<thead>
<tr>
<th>If the control in the DataWindow object is in this band</th>
<th>GetRow returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header</td>
<td>First row on the page</td>
</tr>
<tr>
<td>Group header</td>
<td>First row in the group</td>
</tr>
<tr>
<td>Detail</td>
<td>The row in which the expression occurs</td>
</tr>
<tr>
<td>Group trailer</td>
<td>Last row in the group</td>
</tr>
<tr>
<td>Summary</td>
<td>Last row in the DataWindow object</td>
</tr>
<tr>
<td>Footer</td>
<td>Last row on the page</td>
</tr>
</tbody>
</table>

Examples
This expression for a computed field in the detail band displays the number of each row:

GetRow ()

This expression for a computed field in the header band checks to see if there is data. It returns the number of the first row on the page if there is data, and otherwise returns No Data:

If (GetRow () = 0, "No Data", String (GetRow ()))

See also
“Example 3: creating a row indicator” on page 24
CurrentRow
GetRow on page 689
GetText

Description
Obtains the text that a user has entered in a column.

Syntax
GetText()

Return value
String. Returns the text the user has entered in the current column.

Usage
Use GetText in validation rules to compare what the user has entered to application-defined criteria before it is accepted into the data buffer.

Examples
This validation rule checks that the value the user entered in the column is less than 100:

\[
\text{Integer}(\text{GetText}()) < 100
\]

See also
GetText on page 697

Hour

Description
Obtains the hour in a time value. The hour is based on a 24-hour clock.

Syntax
Hour(time)

Argument | Description
--- | ---
time | The time value from which you want the hour

Return value
Integer. Returns an integer (00–23) containing the hour portion of time.

Examples
This expression returns the current hour:

\[
\text{Hour}(\text{Now}())
\]

This expression returns 19:

\[
\text{Hour}(19:01:31)
\]

See also
Minute
Now
Second
Hour in the PowerScript Reference
If

Description
Evaluates a condition and returns a value based on that condition.

Syntax
\[
\text{If ( boolean, truevalue, falsevalue )}
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>A boolean expression that evaluates to true or false.</td>
</tr>
<tr>
<td>truevalue</td>
<td>The value you want returned if the boolean expression is true. The value can be a string or numeric value.</td>
</tr>
<tr>
<td>falsevalue</td>
<td>The value you want returned if the boolean expression is false. The value can be a string or numeric value.</td>
</tr>
</tbody>
</table>

Return value
The datatype of truevalue or falsevalue. Returns truevalue if boolean is true and falsevalue if it is false. Returns null if an error occurs.

Examples
This expression returns Boss if salary is over $100,000 and Employee if salary is less than or equal to $100,000:

\[
\text{If(salary > 100000, "Boss", "Employee")}
\]

This expression returns Boss if salary is over $100,000, Supervisor if salary is between $12,000 and $100,000, and Clerk if salary is less than or equal to $12,000:

\[
\text{If(salary > 100000, "Boss", \text{If(salary > 12000, "Supervisor", "Clerk")})}
\]

In this example of a validation rule, the value the user should enter in the commission column depends on the price. If price is greater than or equal to 1000, then the commission is between .10 and .20. If price is less than 1000, then the commission must be between .04 and .09. The validation rule is:

\[
\text{Number(GetText())} \geq \text{If(price} \geq \text{1000, .10, .04}) \text{ AND}
\text{Number(GetText())} \leq \text{If(price} \geq \text{1000, .20, .09})
\]

The accompanying error message expression might be:

\[
"\text{Price is " + If(price} \geq \text{1000, "greater than or equal to", "less than"}) + " 1000. Commission must be between " + If(price} \geq \text{1000, ".10", ".04") + " and " + If(price} \geq \text{1000, ".20.", ".09."
\]

See also
“Example 1: counting null values in a column” on page 19
“Example 2: counting male and female employees” on page 21
“Example 3: creating a row indicator” on page 24
“Example 4: displaying all data when a column allows nulls” on page 26
**Int**

Description

Gets the largest whole number less than or equal to a number.

Syntax

```
Int ( n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>The number for which you want the largest whole number that is less than or equal to it</td>
</tr>
</tbody>
</table>

Return value

The datatype of `n`. Returns the largest whole number less than or equal to `n`.

Examples

These expressions return 3.0:

```
Int (3.2)
```

```
Int (3.8)
```

These expressions return -4.0:

```
Int (-3.2)
```

```
Int (-3.8)
```

See also

Ceiling

Integer

Round

Truncate

Int in the *PowerScript Reference*

**Integer**

Description

Converts the value of a string to an integer.

Syntax

```
Integer ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want returned as an integer</td>
</tr>
</tbody>
</table>

Return value

Integer. Returns the contents of `string` as an integer if it succeeds and 0 if `string` is not a number.

Examples

This expression converts the string 24 to an integer:

```
Integer ("24")
```
This expression for a computed field returns “Not a valid age” if age does not contain a number. The expression checks whether the Integer function returns 0, which means it failed to convert the value:

\[
\text{If (Integer(age) <> 0, age, "Not a valid age")}
\]

This expression returns 0:

\[
\text{Integer("3ABC") \quad // 3ABC is not a number}
\]

This validation rule checks that the value in the column the user entered is less than 100:

\[
\text{Integer(GetText()) < 100}
\]

This validation rule for the column named age insures that age contains a string:

\[
\text{Integer(age) <> 0}
\]

See also

IsNumber

Integer in the PowerScript Reference

**IsDate**

**Description**

Tests whether a string value is a valid date.

**Syntax**

\[
\text{IsDate (datevalue)}
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>datevalue</code></td>
<td>A string whose value you want to test to determine whether it is a valid date</td>
</tr>
</tbody>
</table>

**Return value**

Boolean. Returns true if `datevalue` is a valid date and false if it is not.

**Examples**

This expression returns true:

\[
\text{IsDate("Jan 1, 99")}
\]

This expression returns false:

\[
\text{IsDate("Jan 32, 2005")}
\]

This expression for a computed field returns a day number or 0. If the date_received column contains a valid date, the expression returns the number of the day in date_received in the computed field, and otherwise returns 0:

\[
\text{If(IsDate(String(date_received)), DayNumber(date_received), 0)}
\]

See also

IsDate in the PowerScript Reference
**IsExpanded**

**Description**
Tests whether a node in a TreeView DataWindow with the specified TreeView level and that includes the specified row is expanded.

**Syntax**
```
IsExpanded(long row, long level)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>The number of the row that belongs to the node</td>
</tr>
<tr>
<td>level</td>
<td>The TreeView level of the node</td>
</tr>
</tbody>
</table>

**Return value**
Returns true if the group is expanded and false otherwise.

**Usage**
A TreeView DataWindow has several TreeView level bands that can be expanded and collapsed. You can use the IsExpanded function to test whether or not a node in a TreeView DataWindow is expanded.

**Examples**
This expression returns true if the node that contains row 3 at TreeView level 2 is expanded:
```
IsExpanded(3, 2)
```

---

**IsNull**

**Description**
Reports whether the value of a column or expression is null.

**Syntax**
```
IsNull(any)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>A column or expression that you want to test to determine whether its value is null</td>
</tr>
</tbody>
</table>

**Return value**
Boolean. Returns true if any is null and false if it is not.

**Usage**
Use IsNull to test whether a user-entered value or a value retrieved from the database is null.

**Examples**
This expression returns true if either a or b is null:
```
IsNull(a + b)
```
This expression returns true if the value in the salary column is null:
```
IsNull(salary)
```
This expression returns true if the value the user has entered is null:
```
IsNull(GetText())
```
IsNumber

Description
Reports whether the value of a string is a number.

Syntax
IsNumber ( string )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>A string whose value you want to test to determine whether it is a valid number</td>
</tr>
</tbody>
</table>

Return value
Boolean. Returns true if string is a valid number and false if it is not.

Examples
This expression returns true:

IsNumber("32.65")

This expression returns false:

IsNumber("A16")

This expression for a computed field returns "Not a valid age" if age does not contain a number:

If(IsNumber(age), age, "Not a valid age")

To pass this validation rule, Age_nbr must be a number:

IsNumber(Age_nbr) = true

See also
Integer
IsNumber in the PowerScript Reference
IsRowModified

Description Reports whether the row has been modified.
Syntax IsRowModified ()
Return value Boolean. Returns true if the row has been modified and false if it has not.
Usage In a DataWindow object, when you use IsRowModified in bands other than the detail band, it reports on a row in the detail band. See GetRow for a table specifying which row is associated with each band for reporting purposes.
Examples This expression in a computed field in the detail area displays true or false to indicate whether each row has been modified:

    IsRowModified()

This expression defined in the Properties view for the Color property of the computed field displays the text (true) in red if the user has modified any value in the row:

    If(IsRowModified(), 255, 0)

See also GetRow

IsRowNew

Description Reports whether the row has been newly inserted.
Syntax IsRowNew ()
Return value Boolean. Returns true if the row is new and false if it was retrieved from the database.
Usage In a DataWindow object, when you call IsRowNew in bands other than the detail band, it reports on a row in the detail band. See GetRow for a table specifying which row is associated with each band for reporting purposes.
Examples This expression defined in the Properties view for the Protect property of a column prevents the user from modifying the column unless the row has been newly inserted:

    If(IsRowNew(), 0, 1)

See also GetRow
GetItemStatus on page 668
**IsSelected**

**Description**
Determines whether the row is selected. A selected row is highlighted using reverse video.

**Syntax**
\[
\text{IsSelected()}
\]

**Return value**
Boolean. Returns true if the row is selected and false if it is not selected.

**Usage**
When you use IsSelected in bands other than the detail band, it reports on a row in the detail band. See GetRow for a table specifying which row is associated with each band for reporting purposes.

**Examples**
This expression for a computed field in the detail area displays a bitmap if the row is selected:
\[
\text{Bitmap(If(IsSelected(), "beach.bmp", ""))}
\]

This example allows the DataWindow object to display a salary total for all the selected rows. The expression for a computed field in the detail band returns the salary only when the row is selected so that another computed field in the summary band can add up all the selected salaries.

The expression for cf_selected_salary (the computed field in the detail band) is:
\[
\text{If(IsSelected(), salary, 0)}
\]

The expression for the computed field in the summary band is:
\[
\text{Sum(cf_selected_salary for all)}
\]

**See also**
GetRow
IsSelected on page 724

---

**IsTime**

**Description**
Reports whether the value of a string is a valid time value.

**Syntax**
\[
\text{IsTime(timevalue)}
\]

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timevalue</td>
<td>A string whose value you want to test to determine whether it is a valid time</td>
</tr>
</tbody>
</table>

**Return value**
Boolean. Returns true if timevalue is a valid time and false if it is not.
### Large

**Description**
Finds a large value at a specified ranking in a column (for example, third-largest, fifth-largest) and returns the value of another column or expression based on the result.

**Syntax**
```
Large ( returnexp, column, ntop { FOR range { DISTINCT { expres1 {, expres2 {, ... } } } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>returnexp</code></td>
<td>The value you want returned when the large value is found. <code>returnexp</code> includes a reference to a column, but not necessarily the column that is being evaluated for the largest value, so that a value is returned from the same row that contains the large value.</td>
</tr>
<tr>
<td><code>column</code></td>
<td>The column that contains the large value you are searching for. <code>Column</code> can be a column name or a column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
<tr>
<td><code>ntop</code></td>
<td>The ranking of the large value in relation to the column’s largest value. For example, when <code>ntop</code> is 2, <code>Large</code> finds the second-largest value.</td>
</tr>
</tbody>
</table>

**Examples**
This expression returns true:
```powerscript
IsTime("8:00:00 am")
```

This expression returns false:
```powerscript
IsTime("25:00")
```

To pass this validation rule, the value in `start_time` must be a time:
```powerscript
IsTime(start_time)
```

**See also**
`IsTime` in the *PowerScript Reference*
CHAPTER 2  DataWindow Expression Functions

Return value  The datatype of returnexp. Returns the ntop-largest value if it succeeds and –1 if an error occurs.

Usage  If you specify range, Large returns the value in returnexp when the value in column is the ntop-largest value in range. If you specify DISTINCT, Large returns returnexp when the value in column is the ntop-largest value of the distinct values in column, or if you specify expresn, the ntop-largest for each distinct value of expresn.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows are as follows:

- For the Graph or OLE presentation style, Rows is always All
- For Graph controls, Rows can be All, Page, or Group
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies
Max might be faster
If you do not need a return value from another column and you want to find the largest value (ntop = 1), use Max; it is faster.

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

Examples
These expressions return the names of the salespersons with the three largest sales (sum_sales is the sum of the sales for each salesperson) in group 2, which might be the salesregion group. Note that sum_sales contains the values being compared, but Large returns a value in the name column:

- \texttt{Large(name, sum\_sales, 1 for group 2)}
- \texttt{Large(name, sum\_sales, 2 for group 2)}
- \texttt{Large(name, sum\_sales, 3 for group 2)}

This example reports the salesperson with the third-largest sales, considering only the first entry for each person:

- \texttt{Large(name, sum\_sales, 3 for all DISTINCT sum\_sales)}

See also
Small

---

**Last**

Description
Gets the value in the last row in the specified column.

Syntax
\texttt{Last(column \{ FOR range \{ DISTINCT \{ expres1, expres2, \ldots \} \} \})}

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>The column for which you want the value of the last row. Column can be a column name or a column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column.</td>
</tr>
</tbody>
</table>
## CHAPTER 2   DataWindow Expression Functions

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR range</td>
<td>The data that will be included when the value in the last row is found. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>• ALL – (Default) The value in the last of all rows in column.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The value in the last row in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The value in the last row in column on a page.</td>
</tr>
<tr>
<td></td>
<td>For Crosstabs, specify CROSSTAB for range:</td>
</tr>
<tr>
<td></td>
<td>• CROSSTAB – (Crosstabs only) The value in the last row in column in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph and OLE objects, specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>• GRAPH – (Graphs only) The value in the last row in column in the range specified for the Rows option.</td>
</tr>
<tr>
<td></td>
<td>• OBJECT – (OLE objects only) The value in the last row in column in the range specified for the Rows option.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Causes Last to consider only the distinct values in column when determining the last value. For a value of column, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>(optional)</td>
<td>expresn</td>
</tr>
<tr>
<td>(optional)</td>
<td>One or more expressions that you want to evaluate to determine distinct rows. expresn can be the name of a column, a function, or an expression.</td>
</tr>
</tbody>
</table>

### Return value

The datatype of the column. Returns the value in the last row of column. If you specify range, Last returns the value of the last row in column in range.

### Usage

If you specify range, Last determines the value of the last row in column in range. If you specify DISTINCT, Last returns the last distinct value in column, or if you specify expresn, the last distinct value in column where the value of expresn is distinct.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.
LastPos

**Not in validation rules or filter expressions**
You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**
This expression returns the last distinct value in the column named dept_id in group 2:

```
Last (dept_id for group 2 DISTINCT)
```

This expression returns the last value in the column named emp_id in group 2:

```
Last (emp_id for group 2)
```

**See also**
First

---

**LastPos**

**Description**
Finds the last position of a target string in a source string.

**Syntax**
```
LastPos (string1, string2, searchlength)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string1</td>
<td>The string in which you want to find string2.</td>
</tr>
<tr>
<td>string2</td>
<td>The string you want to find in string1.</td>
</tr>
<tr>
<td>searchlength</td>
<td>A long that limits the search to the leftmost searchlength characters of the source string string1. The default is the entire string.</td>
</tr>
</tbody>
</table>

**Return value**
Long. Returns a long whose value is the starting position of the last occurrence of string2 in string1 within the characters specified in searchlength. If string2 is not found in string1 or if searchlength is 0, LastPos returns 0. If any argument's value is null, LastPos returns null.

**Usage**
The LastPos function is case sensitive. The entire target string must be found in the source string.

**Examples**
This statement returns 6, because the position of the last occurrence of RU is position 6:

```
LastPos("BABE RUTH", "RU")
```
This statement returns 3:

\[
\text{LastPos} \left( \text{"BABE RUTH"}, \text{"B"} \right)
\]

This statement returns 0, because the case does not match:

\[
\text{LastPos} \left( \text{"BABE RUTH"}, \text{"be"} \right)
\]

This statement searches the leftmost 4 characters and returns 0, because the only occurrence of RU is after position 4:

\[
\text{LastPos} \left( \text{"BABE RUTH"}, \text{"RU"}, 2 \right)
\]

See also

\[
\text{Pos}
\]

---

**Left**

Description

Obtains a specified number of characters from the beginning of a string.

Syntax

\[
\text{Left} \left( \text{string, } n \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string containing the characters you want</td>
</tr>
<tr>
<td>n</td>
<td>A long specifying the number of characters you want</td>
</tr>
</tbody>
</table>

Return value

String. Returns the leftmost \( n \) characters in \( \text{string} \) if it succeeds and the empty string (""") if an error occurs.

If \( n \) is greater than or equal to the length of the string, \text{Left} returns the entire string. It does not add spaces to make the return value’s length equal to \( n \).

Examples

This expression returns BABE:

\[
\text{Left} \left( \text{"BABE RUTH"}, \text{4} \right)
\]

This expression returns BABE RUTH:

\[
\text{Left} \left( \text{"BABE RUTH"}, \text{40} \right)
\]

This expression for a computed field returns the first 40 characters of the text in the column \text{home_address}:

\[
\text{Left} \left( \text{home_address}, \text{40} \right)
\]

See also

\[
\text{LeftA}
\]
\[
\text{Mid}
\]
\[
\text{Pos}
\]
\[
\text{Right}
\]

Left in the *PowerScript Reference*
**LeftA**

Description Obtains a specified number of bytes from the beginning of a string.

Syntax

```
LeftA (string, n)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string containing the characters you want</td>
</tr>
<tr>
<td>n</td>
<td>A long specifying the number of bytes you want</td>
</tr>
</tbody>
</table>

Return value String. Returns the characters in the leftmost \( n \) bytes in \( string \) if it succeeds and the empty string (""") if an error occurs.

If \( n \) is greater than or equal to the length of the string, \( \text{LeftA} \) returns the entire string. It does not add spaces to make the return value’s length equal to \( n \).

Usage \( \text{LeftA} \) replaces the functionality that \( \text{Left} \) had in DBCS environments in PowerBuilder 9. In SBCS environments, \( \text{Left} \) and \( \text{LeftA} \) return the same results.

See also MidA
PosA
RightA
LeftA in the *PowerScript Reference*

**LeftTrim**

Description Removes spaces from the beginning of a string.

Syntax

```
LeftTrim (string)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want returned with leading spaces deleted</td>
</tr>
</tbody>
</table>

Return value String. Returns a copy of \( string \) with leading spaces deleted if it succeeds and the empty string (""") if an error occurs.

Examples This expression returns RUTH:

```
LeftTrim(" RUTH")
```

This expression for a computed field deletes any leading blanks from the value in the column lname and returns the value preceded by the salutation specified in salut_emp:

```
salut_emp + " " + LeftTrim(lname)
```

See also RightTrim
Trim
LeftTrim in the *PowerScript Reference*
**Len**

**Description**
Reports the length of a string in characters.

**Syntax**
```
Len ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string for which you want the length</td>
</tr>
</tbody>
</table>

**Return value**
Long. Returns a long containing the length of `string` in characters if it succeeds and –1 if an error occurs.

**Examples**
This expression returns 0:
```
Len (" ")
```

This validation rule tests that the value the user entered is fewer than 20 characters:
```
Len(GetText()) < 20
```

**See also**
LenA
Len in the *PowerScript Reference*

---

**LenA**

**Description**
Reports the length of a string in bytes.

**Syntax**
```
LenA ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string for which you want the length</td>
</tr>
</tbody>
</table>

**Return value**
Long. Returns a long containing the length of `string` in bytes if it succeeds and –1 if an error occurs.

**Usage**
LenA replaces the functionality that Len had in DBCS environments in PowerBuilder 9. In SBCS environments, Len and LenA return the same results.

**See also**
Len
LenA in the *PowerScript Reference*
### Log

**Description**
Gets the natural logarithm of a number.

**Syntax**
\[
\text{Log} \ (\ n) \\
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The number for which you want the natural logarithm (base e). The value of ( n ) must be greater than 0.</td>
</tr>
</tbody>
</table>

**Return value**
Double. Returns the natural logarithm of \( n \). An execution error occurs if \( n \) is negative or zero.

**Inverse**
The inverse of the `Log` function is the `Exp` function.

**Examples**
This expression returns 2.302585092:
\[
\text{Log} \ (10) \\
\]
This expression returns -0.693147 ...
\[
\text{Log} \ (0.5) \\
\]
Both these expressions result in an error at runtime:
\[
\text{Log} \ (0) \quad \text{Log} \ (-2) \\
\]

**See also**
Exp  
LogTen  
LogTen in the *PowerScript Reference*  

### LogTen

**Description**
 Gets the base 10 logarithm of a number.

**Syntax**
\[
\text{LogTen} \ (\ n) \\
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The number for which you want the base 10 logarithm. The value of ( n ) must not be negative.</td>
</tr>
</tbody>
</table>
Return value: Double. Returns the base 10 logarithm.

**Obtaining a number**
The expression $10^n$ is the inverse for $\log_{10}(n)$. To obtain $n$ given number ($n_{br} = \log_{10}(n)$), use $n = 10^{n_{br}}$.

**Examples**
This expression returns 1:

```
LogTen(10)
```

The following expressions both return 0:

```
LogTen(1)
LogTen(0)
```

This expression results in an execution error:

```
LogTen(-2)
```

**See also**
Log
LogTen in the *PowerScript Reference*

### Long

**Description**
Converts the value of a string to a long.

**Syntax**
```
Long(string)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want returned as a long</td>
</tr>
</tbody>
</table>

**Return value**
Long. Returns the contents of `string` as a long if it succeeds and 0 if `string` is not a valid number.

**Examples**
This expression returns 2167899876 as a long:

```
Long("2167899876")
```

**See also**
Long in the *PowerScript Reference*
LookUpDisplay

**Description**
Obtains the display value in the code table associated with the data value in the specified column.

**Syntax**
```
LookUpDisplay (column)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>The column for which you want the code table display value</td>
</tr>
</tbody>
</table>

**Return value**
String. Returns the display value when it succeeds and the empty string ("") if an error occurs.

**Usage**
If a column has a code table, a buffer stores a value from the data column of the code table, but the user sees a value from the display column. Use LookUpDisplay to get the value the user sees.

**Code tables and data values and graphs**
When a column that is displayed in a graph has a code table, the graph displays the data values of the code table by default. To display the display values, call this function when you define the graph data.

**Examples**
This expression returns the display value for the column unit_measure:

```
LookUpDisplay(unit_measure)
```

Assume the column product_type has a code table and you want to use it as a category for a graph. To display the product type descriptions instead of the data values in the categories, enter this expression in the Category option on the Data page in the graph’s property sheet:

```
LookUpDisplay(product_type)
```

---

**Lower**

**Description**
Converts all the characters in a string to lowercase.

**Syntax**
```
Lower (string)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want to convert to lowercase letters</td>
</tr>
</tbody>
</table>

**Return value**
String. Returns `string` with uppercase letters changed to lowercase if it succeeds and the empty string ("") if an error occurs.
Examples
This expression returns castle hill:

```plaintext
Lower("Castle Hill")
```

See also
Upper
Lower in the PowerScript Reference

---

**Match**

**Description**
Determines whether a string’s value contains a particular pattern of characters.

**Syntax**

```plaintext
Match ( string, textpattern )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string in which you want to look for a pattern of characters</td>
</tr>
<tr>
<td>textpattern</td>
<td>A string whose value is the text pattern</td>
</tr>
</tbody>
</table>

**Return value**
Boolean. Returns true if `string` matches `textpattern` and false if it does not.

Match also returns false if either argument has not been assigned a value or the pattern is invalid.

**Usage**
Match enables you to evaluate whether a string contains a general pattern of characters. To find out whether a string contains a specific substring, use the Pos function.

`Textpattern` is similar to a regular expression. It consists of metacharacters, which have special meaning, and ordinary characters, which match themselves. You can specify that the string begin or end with one or more characters from a set, or that it contain any characters except those in a set.

A text pattern consists of metacharacters, which have special meaning in the match string, and nonmetacharacters, which match the characters themselves.
The following tables explain the meaning and use of these metacharacters:

<table>
<thead>
<tr>
<th>Metacharacter</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Caret (^)</td>
<td>Matches the beginning of a string</td>
<td>^C matches C at the beginning of a string.</td>
</tr>
<tr>
<td>Dollar sign ($)</td>
<td>Matches the end of a string</td>
<td>$s$ matches s at the end of a string.</td>
</tr>
<tr>
<td>Period (.)</td>
<td>Matches any character</td>
<td>. . . matches three consecutive characters.</td>
</tr>
<tr>
<td>Backslash ()</td>
<td>Removes the following metacharacter’s special characteristics so that it matches itself</td>
<td>$ matches $.</td>
</tr>
<tr>
<td>Character class (a group of characters enclosed in square brackets [ ]))</td>
<td>Matches any of the enclosed characters</td>
<td>[AEIOU] matches A, E, I, O, or U. You can use hyphens to abbreviate ranges of characters in a character class. For example, [A-Za-z] matches any letter.</td>
</tr>
<tr>
<td>Complemented character class (first character inside the square brackets is a caret)</td>
<td>Matches any character not in the group following the caret</td>
<td>[^0-9] matches any character except a digit, and [^A-Za-z] matches any character except a letter.</td>
</tr>
</tbody>
</table>

The metacharacters asterisk (*), plus (+), and question mark (?) are unary operators that are used to specify repetitions in a regular expression:

<table>
<thead>
<tr>
<th>Metacharacter</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>* (asterisk)</td>
<td>Indicates zero or more occurrences</td>
<td>A* matches zero or more As (no As, A, AA, AAA, and so on)</td>
</tr>
<tr>
<td>+ (plus)</td>
<td>Indicates one or more occurrences</td>
<td>A+ matches one A or more than one A (A, AAA, and so on)</td>
</tr>
<tr>
<td>? (question mark)</td>
<td>Indicates zero or one occurrence</td>
<td>A? matches an empty string (“”) or A</td>
</tr>
</tbody>
</table>
Sample patterns  The following table shows various text patterns and sample text that matches each pattern:

<table>
<thead>
<tr>
<th>This pattern</th>
<th>Matches</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB</td>
<td>Any string that contains AB, such as ABA, DEABC, graphAB_one.</td>
</tr>
<tr>
<td>B*</td>
<td>Any string that contains 0 or more Bs, such as AC, B, BB, BBB, ABBBC, and so on. Since B* used alone matches any string, you would not use it alone, but notice its use in some the following examples.</td>
</tr>
<tr>
<td>AB*C</td>
<td>Any string containing the pattern AC or ABC or ABBC, and so on (0 or more Bs).</td>
</tr>
<tr>
<td>AB+C</td>
<td>Any string containing the pattern ABC or ABBC or ABBBC, and so on (1 or more Bs).</td>
</tr>
<tr>
<td>ABB*BC</td>
<td>Any string containing the pattern ABC or ABBC or ABBBC, and so on (1 B plus 0 or more Bs).</td>
</tr>
<tr>
<td>^AB</td>
<td>Any string starting with AB.</td>
</tr>
<tr>
<td>AB?C</td>
<td>Any string containing the pattern AC or ABC (0 or 1 B).</td>
</tr>
<tr>
<td>^[ABC]</td>
<td>Any string starting with A, B, or C.</td>
</tr>
<tr>
<td>^[a-z]+C</td>
<td>A string containing any characters other than a, b, or c.</td>
</tr>
<tr>
<td>^[a-z]+$</td>
<td>A string that begins with any character except a, b, or c.</td>
</tr>
<tr>
<td>[A-Z]+</td>
<td>Any single-character string that is not a lowercase letter (^ and $ indicate the beginning and end of the string).</td>
</tr>
<tr>
<td>[0-9]+S</td>
<td>Any string with one or more uppercase letters.</td>
</tr>
<tr>
<td>[0-9]+S</td>
<td>Any string consisting only of digits.</td>
</tr>
<tr>
<td>[0-9][0-9][0-9]$</td>
<td>Any string consisting of exactly three digits.</td>
</tr>
<tr>
<td>[0-9][0-9][0-9]$</td>
<td>Any string consisting of exactly three digits enclosed in parentheses.</td>
</tr>
</tbody>
</table>

Examples
This validation rule checks that the value the user entered begins with an uppercase letter. If the value of the expression is false, the data fails validation:

\[
\text{Match(GetText(), "^[A-Z]")}
\]

See also
Pos
Match in the PowerScript Reference
Max

Description
Gets the maximum value in the specified column.

Syntax
Max ( column { FOR range { DISTINCT { expres1 {}, expres2 {}, ... } } } )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>The column for which you want the maximum value. The column can be the column name or the column number preceded by a pound sign (#). The column can also be an expression that includes a reference to the column. The data type of column must be numeric.</td>
</tr>
<tr>
<td>FOR range</td>
<td>The data that will be included when the maximum value is found. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td></td>
<td>• ALL – (Default) The maximum value of all rows in column.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The maximum value of rows in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The maximum value of the rows in column on a page.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Causes Max to consider only the distinct values in column when determining the largest value. For a value of column, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>expresn</td>
<td>One or more expressions that you want to evaluate to determine distinct rows. Express can be the name of a column, a function, or an expression.</td>
</tr>
</tbody>
</table>

Return value
The datatype of the column. Returns the maximum value in the rows of column. If you specify range, Max returns the maximum value in column in range.

Usage
If you specify range, Max determines the maximum value in column in range. If you specify DISTINCT, Max returns the maximum distinct value in column, or if you specify expresn, the maximum distinct value in column where the value of expresn is distinct.
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Null values are ignored and are not considered in determining the maximum.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**

This expression returns the maximum of the values in the age column on the page:

```powerquery
Max(age for page)
```

This expression returns the maximum of the values in column 3 on the page:

```powerquery
Max(#3 for page)
```

This expression returns the maximum of the values in the column named age in group 1:

```powerquery
Max(age for group 1)
```

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the maximum of the order amount for the distinct order numbers:

```powerquery
Max(order_amt for all DISTINCT order_nbr)
```

**See also**

Min

Max in the *PowerScript Reference*
**Median**

**Description**
Calculates the median of the values of the column. The median is the middle value in the set of values, for which there is an equal number of values greater and smaller than it.

**Syntax**
```plaintext
Median ( column { FOR range { DISTINCT { expres1 , expres2 , ... } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want the median of the data values. <code>Column</code> can be the column name or the column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
<tr>
<td>FOR range</td>
<td>The data that will be included in the median. For most presentation styles, values for <code>range</code> are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>• ALL – (Default) The median of all values in <code>column</code>.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The median of values in <code>column</code> in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The median of the values in <code>column</code> on a page.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Causes <code>Median</code> to consider only the distinct values in <code>column</code> when determining the median. For a value of <code>column</code>, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>(optional)</td>
<td>expresn (optional) One or more expressions that you want to evaluate to determine distinct rows. <code>Expresn</code> can be the name of a column, a function, or an expression.</td>
</tr>
</tbody>
</table>

**Return value**
The numeric datatype of the column. Returns the median of the values of the rows in `range` if it succeeds and –1 if an error occurs.

**Usage**
If you specify `range`, `Median` returns the median value of `column` in `range`. If you specify `DISTINCT`, `Median` returns the median value of the distinct values in `column`, or if you specify `expresn`, the median of `column` for each distinct value of `expresn`.

96
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range.

Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

In calculating the median, null values are ignored.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**

This expression returns the median of the values in the column named salary:

\[
\text{Median}(\text{salary})
\]

This expression returns the median of the values in the column named salary of group 1:

\[
\text{Median}(\text{salary for group 1})
\]

This expression returns the median of the values in column 5 on the current page:

\[
\text{Median}(\#5 \text{ for page})
\]

This computed field returns Above Median if the median salary for the page is greater than the median for the report:

\[
\text{If} (\text{Median}(\text{salary for page}) > \text{Median}(\text{salary}), \text{"Above Median"}, \text{" "})
\]

This expression for a graph value sets the data value to the median value of the sale_price column:

\[
\text{Median}(\text{sale_price})
\]
This expression for a graph value entered on the Data page in the graph’s property sheet sets the data value to the median value of the sale_price column for the entire graph:

\[ \text{Median}(\text{sale_price for graph}) \]

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the median of the order amount for the distinct order numbers:

\[ \text{Median}(\text{order_amt for all DISTINCT order_nbr}) \]

Avg
Mode

### Mid

**Description**

Obtains a specified number of characters from a specified position in a string.

**Syntax**

\[
\text{Mid}( \text{string}, \text{start} [, \text{length} ] )
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string from which you want characters returned.</td>
</tr>
<tr>
<td>start</td>
<td>A long specifying the position of the first character you want returned (the position of the first character of the string is 1).</td>
</tr>
<tr>
<td>length (optional)</td>
<td>A long whose value is the number of characters you want returned. If you do not enter length or if length is greater than the number of characters to the right of start, Mid returns the remaining characters in the string.</td>
</tr>
</tbody>
</table>

**Return value**

String. Returns characters specified in length of string starting at character start. If start is greater than the number of characters in string, the Mid function returns the empty string ("""). If length is greater than the number of characters remaining after the start character, Mid returns the remaining characters. The return string is not filled with spaces to make it the specified length.

**Examples**

This expression returns "":

\[ \text{Mid}("\text{BABE RUTH}", 40, 5) \]

This expression returns BE RUTH:

\[ \text{Mid}("\text{BABE RUTH}", 3) \]
This expression in a computed field returns ACCESS DENIED if the fourth character in the column password is not R:

\[
\text{If(} \text{Mid(password, 4, 1) = "R", "ENTER", "ACCESS DENIED"})
\]

To pass this validation rule, the fourth character in the column password must be 6:

\[
\text{Mid(password, 4, 1) = "6"}
\]

See also Mid in the PowerScript Reference

### MidA

**Description**

Obtains a specified number of bytes from a specified position in a string.

**Syntax**

\[
\text{MidA} \ ( \text{string, start}, \text{length} \ )
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string from which you want characters returned.</td>
</tr>
<tr>
<td>start</td>
<td>A long specifying the position of the first byte you want returned (the position of the first byte of the string is 1).</td>
</tr>
<tr>
<td>length</td>
<td>A long whose value is the number of bytes you want returned. If you do not enter length or if length is greater than the number of bytes to the right of start, MidA returns the remaining bytes in the string.</td>
</tr>
</tbody>
</table>

**Return value**

String. Returns characters specified by the number of bytes in \text{length of string} starting at the byte specified by \text{start}. If \text{start} is greater than the number of bytes in \text{string}, the MidA function returns the empty string ("""). If \text{length} is greater than the number of bytes remaining after the \text{start} byte, MidA returns the remaining bytes. The return string is not filled with spaces to make it the specified length.

**Usage**

MidA replaces the functionality that Mid had in DBCS environments in PowerBuilder 9. In SBCS environments, Mid and MidA return the same results.

**See also**

Mid

MidA in the PowerScript Reference
**Min**

Description

Gets the minimum value in the specified column.

Syntax

```
Min ( column { FOR range { DISTINCT { expres1 {, expres2 {, ... } } } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want the minimum value. <code>Column</code> can be the column name or the column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
<tr>
<td>FOR range</td>
<td>The data that will be included in the minimum. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>• ALL – (Default) The minimum of all values in <code>column</code>.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The minimum of values in <code>column</code> in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The minimum of the values in <code>column</code> on a page. For Crosstabs, specify CROSSTAB for range:</td>
</tr>
<tr>
<td></td>
<td>• CROSSTAB – (Crosstabs only) The minimum of all values in <code>column</code> in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph and OLE objects, specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>• GRAPH – (Graphs only) The minimum of values in <code>column</code> in the range specified for the Rows option.</td>
</tr>
<tr>
<td></td>
<td>• OBJECT – (OLE objects only) The minimum of values in <code>column</code> in the range specified for the Rows option.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Causes Min to consider only the distinct values in <code>column</code> when determining the minimum value. For a value of <code>column</code>, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>(optional)</td>
<td>expresn</td>
</tr>
</tbody>
</table>

Return value

The datatype of the column. Returns the minimum value in the rows of `column`. If you specify range, Min returns the minimum value in the rows of `column` in range.

Usage

If you specify range, Min determines the minimum value in `column` in range. If you specify DISTINCT, Min returns the minimum distinct value in `column`, or if you specify expresn, the minimum distinct value in `column` where the value of expresn is distinct.
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Null values are ignored and are not considered in determining the minimum.

Not in validation rules or filter expressions
You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

Examples
This expression returns the minimum value in the column named age in group 2:

\[ \text{Min}(\text{age for group 2}) \]

This expression returns the minimum of the values in column 3 on the page:

\[ \text{Min} (#3 \text{ for page}) \]

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the minimum of the order amount for the distinct order numbers:

\[ \text{Min} (\text{order amt for all DISTINCT order_nbr}) \]

See also
Max
Min in the PowerScript Reference
**Minute**

Description

Obtains the number of minutes in the minutes portion of a time value.

Syntax

```
Minute ( time )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>The time value from which you want the minutes</td>
</tr>
</tbody>
</table>

Return value

Integer. Returns the minutes portion of `time` (00 to 59).

Examples

This expression returns 1:

```
Minute(19:01:31)
```

See also

Hour
Second
Minute in the *PowerScript Reference*

---

**Mod**

Description

Obtains the remainder (modulus) of a division operation.

Syntax

```
Mod ( x, y )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>The number you want to divide by y</td>
</tr>
<tr>
<td>y</td>
<td>The number you want to divide into x</td>
</tr>
</tbody>
</table>

Return value

The datatype of `x` or `y`, whichever datatype is more precise.

Examples

This expression returns 2:

```
Mod(20, 6)
```

This expression returns 1.5:

```
Mod(25.5, 4)
```

This expression returns 2.5:

```
Mod(25, 4.5)
```

See also

Mod in the *PowerScript Reference*
# Mode

**Description**
Calculates the mode of the values of the column. The mode is the most frequently occurring value.

**Syntax**
```
Mode ( column { FOR range { DISTINCT { expres1, expres2, ... } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want the mode of the data values. <code>Column</code> can be the column name or the column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
</tbody>
</table>
| `FOR range` (optional) | The data that will be included in the mode. For most presentation styles, values for `range` are:  
  - ALL – (Default) The mode of all values in `column`.  
  - GROUP n – The mode of values in `column` in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.  
  - PAGE – The mode of the values in `column` on a page. For Crosstabs, specify CROSSTAB for `range`:  
    - CROSSTAB – (Crosstabs only) The mode of all values in `column` in the crosstab.  
  For Graph and OLE objects, specify one of the following:  
  - GRAPH – (Graphs only) The mode of values in `column` in the range specified for the Rows option.  
  - OBJECT – (OLE objects only) The mode of values in `column` in the range specified for the Rows option. |
| `DISTINCT` (optional) | Causes `Mode` to consider only the distinct values in `column` when determining the mode. For a value of `column`, the first row found with the value is used and other rows that have the same value are ignored. |
| `expresn` (optional) | One or more expressions that you want to evaluate to determine distinct rows. `Expresn` can be the name of a column, a function, or an expression. |

**Return value**
The numeric datatype of the column. Returns the mode of the values of the rows in `range` if it succeeds and –1 if an error occurs.

**Usage**
If you specify `range`, `Mode` returns the mode of `column` in `range`. If you specify `DISTINCT`, `Mode` returns the mode of the distinct values in `column`, or if you specify `expresn`, the mode of `column` for each distinct value of `expresn`. 
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

In calculating the mode, null values are ignored.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

**Examples**

This expression returns the mode of the values in the column named salary:

```
Mode(salary)
```

This expression returns the mode of the values for group 1 in the column named salary:

```
Mode(salary for group 1)
```

This expression returns the mode of the values in column 5 on the current page:

```
Mode(#5 for page)
```

This computed field returns Above Mode if the mode of the salary for the page is greater than the mode for the report:

```
If(Mode(salary for page) > Mode(salary), "Above Mode", "")
```

This expression for a graph value sets the data value to the mode of the sale_price column:

```
Mode(sale_price)
```

This expression for a graph value entered on the Data page in the graph’s property sheet sets the data value to the mode of the sale_price column for the entire graph:

```
Mode(sale_price for graph)
```
Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the mode of the order amount for the distinct order numbers:

```
Mode(order_amt for all DISTINCT order_nbr)
```

See also
- Avg
- Median

## Month

**Description**

Gets the month of a date value.

**Syntax**

```
Month (date)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date from which you want the month</td>
</tr>
</tbody>
</table>

**Return value**

Integer. Returns an integer (1 to 12) whose value is the month portion of `date`.

**Examples**

This expression returns 1:

```
Month(2005-01-31)
```

This expression for a computed column returns Wrong Month if the month in the column `expected_grad_date` is not 6:

```
If(Month(expected_grad_date) = 6, "June", "Wrong Month")
```

This validation rule expression checks that the value of the month in the date in the column `expected_grad_date` is 6:

```
Month(expected_grad_date) = 6
```

See also
- Day
- Date
- Year
- Month in the *PowerScript Reference*
**Now**

**Description**
Obtains the current time based on the system time of the client machine.

**Syntax**

```
Now()
```

**Return value**
Time. Returns the current time based on the system time of the client machine.

**Usage**
Use `Now` to compare a time to the system time or to display the system time on the screen. The timer interval specified for the DataWindow object determines the frequency at which the value of `Now` is updated. For example, if the timer interval is one second, it is updated every second. The default timer interval is one minute (60,000 milliseconds).

**Examples**

This expression returns the current system time:

```
Now()
```

This expression sets the column value to 8:00 when the current system time is before 8:00 and to the current time if it is after 8:00:

```
If(Now() < 08:00:00, '08:00:00', String(Now()))
```

The displayed time refreshes every time the specified time interval period elapses.

If a static value of time is required (for example, the time when a report has been executed or the retrieve has started), you can use a static text field that you modify as follows:

```
//Set the time when the report was executed in
//the text field t_now
dw1.Modify("t_now.text='"+ String(Now(),"hh:mm")+'"")
//execute the report
dw1.retrieve()
```

**See also**
- If
- Year
- Now in the *PowerScript Reference*
### Number

**Description**
Converts a string to a number.

**Syntax**
\[
\text{Number}(\text{string})
\]

**Argument** | **Description**
--- | ---
string | The string you want returned as a number

**Return value**
A numeric datatype. Returns the contents of string as a number. If string is not a valid number, Number returns 0.

**Examples**
This expression converts the string 24 to a number:
\[
\text{Number}("24")
\]

This expression for a computed field tests whether the value in the age column is greater than 55 and if so displays N/A; otherwise, it displays the value in age:
\[
\text{If}(\text{Number(age)} > 55, \ "N/A", \ age)
\]

This validation rule checks that the number the user entered is between 25,000 and 50,000:
\[
\text{Number(GetText())} > 25000 \ \text{AND} \ \text{Number(GetText())} < 50000
\]

### Page

**Description**
Gets the number of the current page.

**Syntax**
\[
\text{Page}()
\]

**Return value**
Long. Returns the number of the current page.

**Calculating the page count**
The vertical size of the paper less the top and bottom margins is used to calculate the page count. When the print orientation is landscape, the vertical size of the paper is the shorter dimension.

**Examples**
This expression returns the number of the current page:
\[
\text{Page}()
\]
In the DataWindow object’s footer band, this expression for a computed field displays a string showing the current page number and the total number of pages in the report. The result has the format Page n of total:

'Page ' + Page() + ' of ' + PageCount()

PageAbs
PageAcross
PageCount
PageCountAcross

**PageAbs**

<table>
<thead>
<tr>
<th>Description</th>
<th>Gets the absolute number of the current page.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><strong>PageAbs()</strong></td>
</tr>
<tr>
<td>Return value</td>
<td>Long. Returns the absolute number of the current page.</td>
</tr>
<tr>
<td>Usage</td>
<td>Use this function for group reports that have ResetPageCount = yes. It returns the absolute page number, ignoring the page reset count. This enables you to number the grouped pages, but also to obtain the absolute page when the user wants to print the current page, regardless of what that page number is in a grouped page report.</td>
</tr>
<tr>
<td>Examples</td>
<td>This expression returns the absolute number of the current page: <strong>PageAbs()</strong></td>
</tr>
<tr>
<td></td>
<td>This example obtains the absolute page number for the first row on the page in the string variable <em>ret</em>:</td>
</tr>
<tr>
<td></td>
<td>string ret, row</td>
</tr>
<tr>
<td></td>
<td>ret = dw1.Describe(&quot;Evaluate('pageabs()', &quot;+row+&quot;)&quot;)</td>
</tr>
</tbody>
</table>

See also
Page
PageCount
PageCountAcross
PageAcross

Description
Gets the number of the current horizontal page. For example, if a report is twice
the width of the print preview window and the window is scrolled horizontally
to display the portion of the report that was outside the preview, PageAcross
returns 2 because the current page is the second horizontal page.

Syntax
PageAcross ( )

Return value
Long. Returns the number of the current horizontal page if it succeeds and –1
if an error occurs.

Examples
This expression returns the number of the current horizontal page:
PageAcross ()

See also
Page
PageCount
PageCountAcross

PageCount

Description
Gets the total number of pages when a DataWindow object is being viewed in
Print Preview. This number is also the number of printed pages if the
DataWindow object is not wider than the preview window. If the DataWindow
object is wider than the preview window, the number of printed pages will be
greater than the number PageCount gets.

Syntax
PageCount ( )

Return value
Long. Returns the total number of pages.

Usage
PageCount applies to Print Preview.

Calculating the page count
The vertical size of the paper less the top and bottom margins is used to
calculate the page count. When the print orientation is landscape, the vertical
size of the paper is the shorter dimension.

Examples
This expression returns the number of pages:
PageCount ()
In the DataWindow object’s footer band, this expression for a computed field displays a string showing the current page number and the total number of pages in the report. The result has the format *Page n of total:*

```
'Page ' + Page() + ' of ' + PageCount()
```

See also
- Page
- PageAcross
- PageCountAcross

### PageCountAcross

**Description**

Gets the total number of horizontal pages that are wider than the Print Preview window when a DataWindow object is viewed in Print preview.

**Syntax**

```
PageCountAcross()
```

**Return value**

Long. Returns the total number of horizontal pages if it succeeds and –1 if an error occurs.

**Usage**

PageCountAcross applies to Print Preview.

**Examples**

This expression returns the number of horizontal pages in the Print Preview window:

```
PageCountAcross()
```

See also
- Page
- PageAcross
- PageCount

### Percent

**Description**

Gets the percentage that the current value represents of the total of the values in the column.

**Syntax**

```
Percent( column { FOR range { DISTINCT { expres1 {, expres2 {, ... } } } } } )
```
### CHAPTER 2  DataWindow Expression Functions

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want the value of each row expressed as a percentage of the total of the values of the column. <code>Column</code> can be the column name or the column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
</tbody>
</table>
| FOR `range` (optional) | The data to be included in the percentage. For most presentation styles, values for `range` are:  
- ALL – (Default) The percentage that the current value represents of all rows in `column`.  
- GROUP `n` – The percentage that the current value represents of rows in `column` in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.  
- PAGE – The percentage that the current value represents of the rows in `column` on a page.  
For Crosstabs, specify CROSSTAB for `range`:  
- CROSSTAB – (Crosstabs only) The percentage that the current value represents of all rows in `column` in the crosstab.  
For Graph and OLE objects, specify one of the following:  
- GRAPH – (Graphs only) The percentage that the current value represents of values in `column` in the range specified for the Rows option.  
- OBJECT – (OLE objects only) The percentage that the current value represents of values in `column` in the range specified for the Rows option. |
| DISTINCT (optional) | Causes Percent to consider only the distinct values in `column` when determining the percentage. For a value of `column`, the first row found with the value is used and other rows that have the same value are ignored. |
| `expresn` (optional) | One or more expressions that you want to evaluate to determine distinct rows. `Expresn` can be the name of a column, a function, or an expression. |

### Return value
A numeric datatype (decimal, double, integer, long, or real). Returns the percentage the current row of `column` represents of the total value of the column.

### Usage
Usually you use Percent in a column to display the percentage for each row. You can also use Percent in a header or trailer for a group. In the header, Percent displays the percentage for the first value in the group, and in the trailer, for the last value in the group.
If you specify `range`, `Percent` returns the percentage that the current row of `column` represents relative to the total value of `range`. For example, if column 5 is salary, `Percent(#5 for group 1)` is equivalent to 
\[
\text{salary/(Sum\{Salary for group 1\})}
\]

If you specify `DISTINCT`, `Percent` returns the percent that a distinct value in `column` represents of the total value of `column`. If you specify `expresn`, `Percent` returns the percent that the value in `column` represents of the total for `column` in a row in which the value of `expresn` is distinct.

### Formatting the percent value

The percentage is displayed as a decimal value unless you specify a format for the result. A display format can be part of the computed field’s definition.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the `Rows` setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for `Rows` include the following:

- For the Graph or OLE presentation style, `Rows` is always All.
- For Graph controls, `Rows` can be All, Page, or Group.
- For OLE controls, `Rows` can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Null values are ignored and are not considered in the calculation.

### Not in validation rules, filter expressions, or crosstabs

You cannot use `Percent` or other aggregate functions in validation rules or filter expressions. `Percent` does not work for crosstabs; specifying “for crosstab” as a range is not available for `Percent`.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

### Examples

This expression returns the value of each row in the column named salary as a percentage of the total of salary:

\[
\text{Percent\{salary\}}
\]

This expression returns the value of each row in the column named cost as a percentage of the total of cost in group 2:

\[
\text{Percent\{cost for group 2\}}
\]
This expression entered in the Value box on the Data tab page in the Graph Object property sheet returns the value of each row in the qty_ordered as a percentage of the total for the column in the graph:

\[
\text{Percent}(\text{qty\_ordered for graph})
\]

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the order amount as a percentage of the total order amount for the distinct order numbers:

\[
\text{Percent}(\text{order\_amt for all DISTINCT order\_nbr})
\]

See also
CumulativePercent

\[\text{Pi}\]

**Description**
Multiplies pi by a specified number.

**Syntax**
\[
\text{Pi}(n)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(n)</td>
<td>The number you want to multiply by pi (3.14159265358979323...)</td>
</tr>
</tbody>
</table>

**Return value**
Double. Returns the result of multiplying \(n\) by pi if it succeeds and –1 if an error occurs.

**Usage**
Use \(\text{Pi}\) to convert angles to and from radians.

**Examples**
This expression returns pi:

\[
\text{Pi}(1)
\]

Both these expressions return the area of a circle with the radius \(\text{Rad}\):

\[
\text{Pi}(1) \cdot \text{Rad}^2
\]

\[
\text{Pi}(\text{Rad}^2)
\]

This expression computes the cosine of a 45-degree angle:

\[
\cos(45.0 \ast (\text{Pi}(2)/360))
\]

**See also**
Cos
Sin
Tan
\(\text{Pi}\) in the *PowerScript Reference*
**Pos**

Description
Finds one string within another string.

Syntax
```
Pos (string1, string2, [start])
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string1</td>
<td>The string in which you want to find string2.</td>
</tr>
<tr>
<td>string2</td>
<td>The string you want to find in string1.</td>
</tr>
<tr>
<td>start</td>
<td>A long indicating where the search will begin in string. The default is 1. (optional)</td>
</tr>
</tbody>
</table>

Return value
Long. Returns a long whose value is the starting position of the first occurrence of string2 in string1 after the position specified in start. If string2 is not found in string1 or if start is not within string1, Pos returns 0.

Usage
The Pos function is case sensitive.

Examples
This expression returns the position of the letter a in the value of the last_name column:
```
Pos(last_name, "a")
```
This expression returns 6:
```
Pos("BABE RUTH", "RU")
```
This expression returns 1:
```
Pos("BABE RUTH", "B")
```
This expression returns 0 (because the case does not match):
```
Pos("BABE RUTH", "be")
```
This expression returns 0 (because it starts searching at position 5, after the occurrence of BE):
```
Pos("BABE RUTH", "BE", 5)
```

CHAPTER 2  DataWindow Expression Functions

**PosA**

**Description**  
Finds one string within another string.

**Syntax**  
`PosA ( string1, string2 [, start ] )`

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>string1</code></td>
<td>The string in which you want to find <code>string2</code>.</td>
</tr>
<tr>
<td><code>string2</code></td>
<td>The string you want to find in <code>string1</code>.</td>
</tr>
<tr>
<td><code>start</code> (optional)</td>
<td>A long indicating the position in bytes where the search will begin in <code>string</code>. The default is 1.</td>
</tr>
</tbody>
</table>

**Return value**  
Long. Returns a long whose value is the starting position of the first occurrence of `string2` in `string1` after the position in bytes specified in `start`. If `string2` is not found in `string1` or if `start` is not within `string1`, `PosA` returns 0.

**Usage**  
`PosA` replaces the functionality that `Pos` had in DBCS environments in PowerBuilder 9. In SBCS environments, `Pos` and `PosA` return the same results.

**See also**  
`LastPos`, `LeftA`, `MidA`, `Pos`, `RightA`, `PosA` in the *PowerScript Reference*

**ProfileInt**

**Description**  
Obtains the integer value of a setting in the specified profile file.

**Syntax**  
`ProfileInt ( filename, section, key, default )`

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>filename</code></td>
<td>A string whose value is the name of the profile file. If you do not specify a full path, <code>ProfileInt</code> uses the operating system’s standard file search order to find the file.</td>
</tr>
<tr>
<td><code>section</code></td>
<td>A string whose value is the name of a group of related values in the profile file. In the file, section names are in square brackets. Do not include the brackets in <code>section</code>. <code>Section</code> is not case sensitive.</td>
</tr>
</tbody>
</table>
## ProfileInt

### Argument | Description
---|---
**key** | A string specifying the setting name in *section* whose value you want. The setting name is followed by an equal sign in the file. Do not include the equal sign in *key*. *Key* is not case sensitive.
**default** | An integer value that ProfileInt returns if *filename* is not found, if *section* or *key* does not exist in *filename*, or if the value of *key* cannot be converted to an integer.

**Return value**

Integer. Returns default if *filename* is not found, *section* is not found in *filename*, *key* is not found in *section*, or the value of *key* is not an integer. Returns –1 if an error occurs.

**Usage**

Use ProfileInt and ProfileString to get configuration settings from a profile file you have designed for your application. ProfileInt and ProfileString can read files with ANSI or UTF16-LE encoding on Windows systems, and ANSI or UTF16-BE encoding on UNIX systems.

**Using a DataWindow object in different environments**

**PowerBuilder**  You can use PowerScript SetProfileString to change values in the profile file to customize your application’s configuration at runtime. Before you make changes, you can use ProfileInt and ProfileString to obtain the original settings so you can optionally restore them when the user exits the application.

**Web control**  ProfileInt always returns the value of default. It does not open a file on the user’s machine; doing so would be a security violation.

**Examples**

This example uses the following *PROFILE.INI* file:

```ini
[MyApp]
Maximized=1

[Security]
Class = 7
```

This expression tries to return the integer value of the keyword Minimized in section MyApp of file C:\PROFILE.INI. It returns 3 if there is no MyApp section or no Minimized keyword in the MyApp section. Based on the sample file above, it returns 3:

`ProfileInt("C:\PROFILE.INI", "MyApp", "minimized", 3)`

**See also**

ProfileString
ProfileInt in the *PowerScript Reference*
ProfileString

Description
Obtains the string value of a setting in the specified profile file.

Syntax
ProfileString( filename, section, key, default )

Argument | Description
---|---
filename | A string whose value is the name of the profile file. If you do not specify a full path, ProfileString uses the operating system’s standard file search order to find the file.
section | A string whose value is the name of a group of related values in the profile file. In the file, section names are in square brackets. Do not include the brackets in section. Section is not case sensitive.
key | A string specifying the setting name in section whose value you want. The setting name is followed by an equal sign in the file. Do not include the equal sign in key. Key is not case sensitive.
default | A string value that ProfileString returns if filename is not found, if section or key does not exist in filename, or if the value of key cannot be converted to an integer.

Return value
String, with a maximum length of 4096 characters. Returns the string from key within section within filename. If filename is not found, section is not found in filename, or key is not found in section, ProfileString returns default. If an error occurs, it returns the empty string (“”).

Usage
Use ProfileInt and ProfileString to get configuration settings from a profile file you have designed for your application. ProfileInt and ProfileString can read files with ANSI or UTF16-LE encoding on Windows systems, and ANSI or UTF16-BE encoding on UNIX systems.
Using a DataWindow object in different environments

**PowerBuilder** You can use PowerScript SetProfileString to change values in the profile file to customize your application’s configuration at runtime. Before you make changes, you can use ProfileInt and ProfileString to obtain the original settings so you can optionally restore them when the user exits the application.

**Web control** ProfileString always returns the value of *default*. It does not open a file on the user’s machine; doing so would be a security violation.

### Examples

This example uses the following section in the `PROFILE.INI` file:

```
[Employee]
Name="Smith"

[Dept]
Name="Marketing"
```

This expression returns the string for the keyword Name in section Employee in file `C:\PROFILE.INI`. It returns None if the section or keyword does not exist. In this case it returns Smith:

```
ProfileString("C:\PROFILE.INI", "Employee", "Name", "None")
```

---

**Rand**

**Description** Obtains a random whole number between 1 and a specified upper limit.

**Syntax**

```
Rand ( n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n</code></td>
<td>The upper limit of the range of random numbers you want returned. The lower limit is always 1. The upper limit cannot exceed 32,767.</td>
</tr>
</tbody>
</table>

**Return value** A numeric datatype, the datatype of `n`. Returns a random whole number between 1 and `n`.

**Usage** The sequence of numbers generated by repeated calls to the Rand function is a computer-generated pseudorandom sequence.
You can control whether the sequence is different each time your application runs by calling the PowerScript Randomize function to initialize the random number generator.

**Examples**

This expression returns a random whole number between 1 and 10:

```
Rand(10)
```

**See also**

Rand in the *PowerScript Reference*
Randomize in the *PowerScript Reference*

---

**Real**

**Description**

Converts a string value to a real datatype.

**Syntax**

```
Real ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string whose value you want to convert to a real</td>
</tr>
</tbody>
</table>

**Return value**

Real. Returns the contents of a string as a real. If `string` is not a valid number, `Real` returns 0.

**Examples**

This expression converts 24 to a real:

```
Real("24")
```

This expression returns the value in the column `temp_text` as a real:

```
Real(temp_text)
```

**See also**

Real in the *PowerScript Reference*
RelativeDate

Description
Obtains the date that occurs a specified number of days after or before another date.

Syntax
```
RelativeDate ( date, n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>A date value</td>
</tr>
<tr>
<td>n</td>
<td>An integer indicating the number of days</td>
</tr>
</tbody>
</table>

Return value
Date. Returns the date that occurs \( n \) days after \( date \) if \( n \) is greater than 0. Returns the date that occurs \( n \) days before \( date \) if \( n \) is less than 0.

Examples
This expression returns 2005-02-10:
```
RelativeDate(2005-01-31, 10)
```
This expression returns 2005-01-21:
```
RelativeDate(2005-01-31, -10)
```

See also
DaysAfter
RelativeDate in the PowerScript Reference

RelativeTime

Description
Obtains a time that occurs a specified number of seconds after or before another time within a 24-hour period.

Syntax
```
RelativeTime ( time, n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>A time value</td>
</tr>
<tr>
<td>n</td>
<td>A long number of seconds</td>
</tr>
</tbody>
</table>

Return value
Time. Returns the time that occurs \( n \) seconds after \( time \) if \( n \) is greater than 0. Returns the time that occurs \( n \) seconds before \( time \) if \( n \) is less than 0. The maximum return value is 23:59:59.

Examples
This expression returns 19:01:41:
```
RelativeTime(19:01:31, 10)
```
This expression returns 19:01:21:
```
RelativeTime(19:01:31, -10)
```
Replace

Description
Replaces a portion of one string with another.

Syntax
\textbf{Replace ( }\textit{string1}, \textit{start}, \textit{n}, \textit{string2} \textbf{)}

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{string1}</td>
<td>The string in which you want to replace characters with \textit{string2}.</td>
</tr>
<tr>
<td>\textit{start}</td>
<td>A long whose value is the number of the first character you want replaced. (The first character in the string is number 1.)</td>
</tr>
<tr>
<td>\textit{n}</td>
<td>A long whose value is the number of characters you want to replace.</td>
</tr>
<tr>
<td>\textit{string2}</td>
<td>The string that replaces characters in \textit{string1}. The number of characters in \textit{string2} can be greater than, equal to, or fewer than the number of characters you are replacing.</td>
</tr>
</tbody>
</table>

Return value
String. Returns the string with the characters replaced if it succeeds and the empty string ("") if it fails.

Usage
If the start position is beyond the end of the string, \textbf{Replace} appends \textit{string2} to \textit{string1}. If there are fewer characters after the start position than specified in \textit{n}, \textbf{Replace} replaces all the characters to the right of character start.

If \textit{n} is zero, then in effect \textbf{Replace} inserts \textit{string2} into \textit{string1}.

Examples
This expression changes the last two characters of the string David to e to make it Dave:
\begin{verbatim}
Replace("David", 4, 2, "e")
\end{verbatim}

This expression returns MY HOUSE:
\begin{verbatim}
Replace("YOUR HOUSE", 1, 4, "MY")
\end{verbatim}

This expression returns Closed for the Winter:
\begin{verbatim}
Replace("Closed for Vacation", 12, 8, "the Winter")
\end{verbatim}

See also
ReplaceA
Replace in the \textit{PowerScript Reference}
ReplaceA

Description
Replaces a portion of one string with another.

Syntax
ReplaceA (string1, start, n, string2)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string1</td>
<td>The string in which you want to replace bytes with string2.</td>
</tr>
<tr>
<td>start</td>
<td>A long whose value is the number of the first byte you want replaced. (The first byte in the string is number 1.)</td>
</tr>
<tr>
<td>n</td>
<td>A long whose value is the number of bytes you want to replace.</td>
</tr>
<tr>
<td>string2</td>
<td>The string that replaces bytes in string1. The number of bytes in string2 can be greater than, equal to, or fewer than the number of bytes you are replacing.</td>
</tr>
</tbody>
</table>

Return value
String. Returns the string with the bytes replaced if it succeeds and the empty string ("") if it fails.

Usage
If the start position is beyond the end of the string, ReplaceA appends string2 to string1. If there are fewer bytes after the start position than specified in n, ReplaceA replaces all the bytes to the right of character start.

If n is zero, then in effect ReplaceA inserts string2 into string1.

ReplaceA replaces the functionality that Replace had in DBCS environments in PowerBuilder 9. In SBCS environments, Replace and ReplaceA return the same results.

See also
Replace
ReplaceA in the PowerScript Reference

RGB

Description
Calculates the long value that represents the color specified by numeric values for the red, green, and blue components of the color.

Syntax
RGB (red, green, blue)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>red</td>
<td>The integer value of the red component of the color</td>
</tr>
<tr>
<td>green</td>
<td>The integer value of the green component of the color</td>
</tr>
<tr>
<td>blue</td>
<td>The integer value of the blue component of the color</td>
</tr>
</tbody>
</table>
Return value

Long. Returns the long that represents the color created by combining the values specified in red, green, and blue. If an error occurs, RGB returns null.

Usage

The formula for combining the colors is:

\[ \text{Red} + (256 \times \text{Green}) + (65536 \times \text{Blue}) \]

Use RGB to obtain the long value required to set the color for text and drawing objects. You can also set an object’s color to the long value that represents the color. The RGB function provides an easy way to calculate that value.

**Determining color components**  The value of a component color is an integer between 0 and 255 that represents the amount of the component that is required to create the color you want. The lower the value, the darker the color; the higher the value, the lighter the color.

The following table lists red, green, and blue values for the 16 standard colors:

<table>
<thead>
<tr>
<th>Color</th>
<th>Red value</th>
<th>Green value</th>
<th>Blue value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>White</td>
<td>255</td>
<td>255</td>
<td>255</td>
</tr>
<tr>
<td>Light Gray</td>
<td>192</td>
<td>192</td>
<td>192</td>
</tr>
<tr>
<td>Dark Gray</td>
<td>128</td>
<td>128</td>
<td>128</td>
</tr>
<tr>
<td>Red</td>
<td>255</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Dark Red</td>
<td>128</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Green</td>
<td>0</td>
<td>255</td>
<td>0</td>
</tr>
<tr>
<td>Dark Green</td>
<td>0</td>
<td>128</td>
<td>0</td>
</tr>
<tr>
<td>Blue</td>
<td>0</td>
<td>0</td>
<td>255</td>
</tr>
<tr>
<td>Dark Blue</td>
<td>0</td>
<td>0</td>
<td>128</td>
</tr>
<tr>
<td>Magenta</td>
<td>255</td>
<td>0</td>
<td>255</td>
</tr>
<tr>
<td>Dark Magenta</td>
<td>128</td>
<td>0</td>
<td>128</td>
</tr>
<tr>
<td>Cyan</td>
<td>0</td>
<td>255</td>
<td>255</td>
</tr>
<tr>
<td>Dark Cyan</td>
<td>0</td>
<td>128</td>
<td>128</td>
</tr>
<tr>
<td>Yellow</td>
<td>255</td>
<td>255</td>
<td>0</td>
</tr>
<tr>
<td>Brown</td>
<td>128</td>
<td>128</td>
<td>0</td>
</tr>
</tbody>
</table>

**Examples**

This expression returns as a long 8421376, which represents dark cyan:

\[ \text{RGB}(0, 128, 128) \]

This expression for the Background.Color property of a salary column returns a long that represents red if an employee’s salary is greater than $50,000 and white if salary is less than or equal to $50,000:

\[ \text{If}(\text{salary}>50000, \text{RGB}(255, 0, 0), \text{RGB}(255, 255, 255)) \]
Right

Description
Obtains a specified number of characters from the end of a string.

Syntax
Right ( string, n )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string from which you want characters returned</td>
</tr>
<tr>
<td>n</td>
<td>A long whose value is the number of characters you want returned from the right end of string</td>
</tr>
</tbody>
</table>

Return value
String. Returns the rightmost n characters in string if it succeeds and the empty string (""") if an error occurs.

If n is greater than or equal to the length of the string, Right returns the entire string. It does not add spaces to make the return value’s length equal to n.

Examples
This expression returns HILL:

Right ("CASTLE HILL", 4)

This expression returns CASTLE HILL:

Right ("CASTLE HILL", 75)

See also
Left
Mid
Pos
Right in the PowerScript Reference
RightA

Description
Obtains a specified number of characters from the end of a string.

Syntax
Right ( string, n )

Argument | Description
--- | ---
string | The string from which you want characters returned
n | A long whose value is the number of characters you want returned from the right end of string

Return value
String. Returns the rightmost n characters in string if it succeeds and the empty string ("") if an error occurs.

Usage
RightA replaces the functionality that Right had in DBCS environments in PowerBuilder 9. In SBCS environments, Right and RightA return the same results.

See also
LeftA
MidA
PosA
Right

RightTrim

Description
Removes spaces from the end of a string.

Syntax
RightTrim ( string )

Argument | Description
--- | ---
string | The string you want returned with trailing blanks deleted

Return value
String. Returns a copy of string with trailing blanks deleted if it succeeds and the empty string ("") if an error occurs.

Examples
This expression returns RUTH:

RightTrim ("RUTH ")

See also
LeftTrim
Trim
RightTrim in the PowerScript Reference
**Round**

**Description**
Rounds a number to the specified number of decimal places.

**Syntax**

\[
\text{Round} \left( x, n \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x )</td>
<td>The number you want to round.</td>
</tr>
<tr>
<td>( n )</td>
<td>The number of decimal places to which you want to round ( x ). Valid values are 0 through 28.</td>
</tr>
</tbody>
</table>

**Return value**
Decimal. If \( n \) is positive, Round returns \( x \) rounded to the specified number of decimal places. If \( n \) is negative, it returns \( x \) rounded to \((-n+1)\) places before the decimal point. Returns –1 if it fails.

**Examples**

This expression returns 9.62:

\[
\text{Round} \left( 9.624, \ 2 \right)
\]

This expression returns 9.63:

\[
\text{Round} \left( 9.625, \ 2 \right)
\]

This expression returns 9.600:

\[
\text{Round} \left( 9.6, \ 3 \right)
\]

This expression returns -9.63:

\[
\text{Round} \left( -9.625, \ 2 \right)
\]

This expression returns -10:

\[
\text{Round} \left( -9.625, \ -1 \right)
\]

**See also**
Ceiling
Int
Truncate
Round in the *PowerScript Reference*
This expression in a computed field returns a warning if no data exists and the number of rows if there is data:

\[
\text{If}(\text{RowCount}() = 0, \text{"No Data"}, \text{String(RowCount())})
\]

See also
RowCount on page 778

**RowHeight**

**Description**
Reports the height of a row associated with a band in a DataWindow object.

**Syntax**

\[
\text{RowHeight}()
\]

**Return value**
Long. Returns the height of the row in the units specified for the DataWindow object if it succeeds, and –1 if an error occurs.

**Usage**
When you call RowHeight in a band other than the detail band, it reports on a row in the detail band. See GetRow for a table specifying which row is associated with each band for reporting purposes.

When a band has Autosize Height set to true, you should avoid using the RowHeight DataWindow expression function to set the height of any element in the row. Doing so can result in a logical inconsistency between the height of the row and the height of the element. If you need to use RowHeight, you must set the Y coordinate of the element to 0 on the Position page in the Properties view, otherwise the bottom of the element might be clipped. You must do this for every element that uses such an expression. If you move any elements in the band, make sure that their Y coordinates are still set to 0.

You should not use an expression whose runtime value is greater than the value returned by RowHeight. For example, you should not set the height of a column to \(\text{rowheight}() + 30\). Such an expression produces unpredictable results at runtime.

**Examples**
This expression for a computed field in the detail band displays the height of each row:

\[
\text{RowHeight}()
\]

See also
GetRow
Second

Description
Obtains the number of seconds in the seconds portion of a time value.

Syntax
Second (time)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>The time value from which you want the seconds</td>
</tr>
</tbody>
</table>

Return value
Integer. Returns the seconds portion of time (00 to 59).

Examples
This expression returns 31:
Second(19:01:31)

See also
Hour
Minute
Second in the PowerScript Reference

SecondsAfter

Description
Gets the number of seconds one time occurs after another.

Syntax
SecondsAfter (time1, time2)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time1</td>
<td>A time value that is the start time of the interval being measured</td>
</tr>
<tr>
<td>time2</td>
<td>A time value that is the end time of the interval</td>
</tr>
</tbody>
</table>

Return value
Long. Returns the number of seconds time2 occurs after time1. If time2 occurs before time1, SecondsAfter returns a negative number.

Examples
This expression returns 15:
SecondsAfter(21:15:30, 21:15:45)

This expression returns -15:
SecondsAfter(21:15:45, 21:15:30)

This expression returns 0:
SecondsAfter(21:15:45, 21:15:45)

See also
DaysAfter
SecondsAfter in the PowerScript Reference
**Sign**

Description
Reports whether the number is negative, zero, or positive by checking its sign.

Syntax
\[ \text{Sign}(n) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The number for which you want to determine the sign</td>
</tr>
</tbody>
</table>

Return value
Integer. Returns a number \((-1, 0, \text{ or } 1)\) indicating the sign of \( n \).

Examples
This expression returns 1 (the number is positive):
\[ \text{Sign}(5) \]
This expression returns 0:
\[ \text{Sign}(0) \]
This expression returns \(-1\) (the number is negative):
\[ \text{Sign}(-5) \]

See also
Sign in the PowerScript Reference

**Sin**

Description
Calculates the sine of an angle.

Syntax
\[ \text{Sin}(n) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>The angle (in radians) for which you want the sine</td>
</tr>
</tbody>
</table>

Return value
Double. Returns the sine of \( n \) if it succeeds and \(-1\) if an error occurs.

Examples
This expression returns .8414709848078965:
\[ \text{Sin}(1) \]
This expression returns 0:
\[ \text{Sin}(0) \]
This expression returns 0:
\[ \text{Sin}(\pi(1)) \]

See also
Cos
Pi
Tan
Sin in the PowerScript Reference
Small

Description
Finds a small value at a specified ranking in a column (for example, third-smallest, fifth-smallest) and returns the value of another column or expression based on the result.

Syntax
```
Small ( returnexp, column, nbottom { FOR range { DISTINCT { expres1 {, expres2 {, ... } } } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>returnexp</td>
<td>The value you want returned when the small value is found. Returnexp includes a reference to a column, but not necessarily the column that is being evaluated for the small value, so that a value is returned from the same row that contains the small value.</td>
</tr>
<tr>
<td>column</td>
<td>The column that contains the small value you are searching for. Column can be a column name or a column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. The datatype of column must be numeric.</td>
</tr>
<tr>
<td>nbottom</td>
<td>The relationship of the small value to the column’s smallest value. For example, when nbottom is 2, Small finds the second-smallest value.</td>
</tr>
<tr>
<td>FOR range</td>
<td>The data that will be included when finding the small value. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>• ALL – (Default) The small value of all rows in column.</td>
</tr>
<tr>
<td></td>
<td>• GROUP n – The small value of rows in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The small value of the rows in column on a page. For Crosstabs, specify CROSSTAB for range:</td>
</tr>
<tr>
<td></td>
<td>• CROSSTAB – (Crosstabs only) The small value of all rows in column in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph and OLE objects, specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>• GRAPH – (Graphs only) The small value in column in the range specified for the Rows option.</td>
</tr>
<tr>
<td></td>
<td>• OBJECT – (OLE objects only) The small value in column in the range specified for the Rows option.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Causes Small to consider only the distinct values in column when determining the small value. For a value of column, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>(optional)</td>
<td>expresn</td>
</tr>
</tbody>
</table>
Return value

The datatype of `returnexp`. Returns the `nbottom`-smallest value if it succeeds and -1 if an error occurs.

Usage

If you specify `range`, `Small` returns the value in `returnexp` when the value in `column` is the `nbottom`-smallest value in `range`. If you specify `DISTINCT`, `Small` returns `returnexp` when the value in `column` is the `nbottom`-smallest value of the distinct values in `column`, or if you specify `expresn`, the `nbottom`-smallest for each distinct value of `expresn`.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range.

Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Min might be faster

If you do not need a return value from another column and you want to find the smallest value (`nbottom = 1`), use `Min`; it is faster.

Not in validation rules or filter expressions

You cannot use this or other aggregate functions in validation rules or filter expressions.

Examples

These expressions return the names of the salespersons with the three smallest sales (sum_sales is the sum of the sales for each salesperson) in group 2, which might be the salesregion group. Note that sum_sales contains the values being compared, but `Small` returns a value in the name column:

```
Small(name, sum_sales, 1 for group 2)
Small(name, sum_sales, 2 for group 2)
Small(name, sum_sales, 3 for group 2)
```

This example reports the salesperson with the third-smallest sales, considering only the first entry for each salesperson:

```
Small(name, sum_sales, 3 for all DISTINCT sum_sales)
```

See also

`Large`
**Space**

Description: Builds a string of the specified length whose value consists of spaces.

Syntax:

```
Space ( n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n</code></td>
<td>A long whose value is the length of the string you want filled with spaces</td>
</tr>
</tbody>
</table>

Return value: String. Returns a string filled with `n` spaces if it succeeds and the empty string (""") if an error occurs.

Examples: This expression for a computed field returns 10 spaces in the computed field if the value of the rating column is Top Secret; otherwise, it returns the value in rating:

```
If(rating = "Top Secret", Space(10), rating)
```

See also: Fill

Space in the *PowerScript Reference*

---

**Sqrt**

Description: Calculates the square root of a number.

Syntax:

```
Sqrt ( n )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n</code></td>
<td>The number for which you want the square root</td>
</tr>
</tbody>
</table>

Return value: Double. Returns the square root of `n`.

Usage: `Sqrt(n)` is the same as `n ^ .5`.

Taking the square root of a negative number causes an execution error.

Examples: This expression returns 1.414213562373095:

```
Sqrt(2)
```

This expression results in an error at execution time:

```
Sqrt(-2)
```

See also: Sqrt in the *PowerScript Reference*
### StDev

#### Description
Calculates an estimate of the standard deviation for the specified column. Standard deviation is a measurement of how widely values vary from average.

#### Syntax
```
StDev ( column { FOR range { DISTINCT { expres1 {, expres2 {, ... } } } } } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>column</code></td>
<td>The column for which you want an estimate for the standard deviation of the values in the rows. <code>Column</code> can be the column name or the column number preceded by a pound sign (#). <code>Column</code> can also be an expression that includes a reference to the column. The datatype of <code>column</code> must be numeric.</td>
</tr>
</tbody>
</table>
| `FOR range` (optional) | The data to be included in the estimate of the standard deviation. For most presentation styles, values for `range` are:
  * ALL – (Default) The estimate of the standard deviation for all values in `column`.
  * GROUP `n` – The estimate of the standard deviation for values in `column` in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.
  * PAGE – The estimate of the standard deviation for the values in `column` on a page.
  For Crosstabs, specify CROSSTAB for `range` to indicate the standard deviation for all values in `column` in the crosstab.
  For Graph objects specify GRAPH and for OLE objects specify OBJECT to indicate the standard deviation for values in `column` in the range specified for the Rows option. |
| `DISTINCT` (optional) | Causes `StDev` to consider only the distinct values in `column` when determining the standard deviation. For a value of `column`, the first row found with the value is used and other rows that have the same value are ignored. |
| `expresn` (optional) | One or more expressions that you want to evaluate to determine distinct rows. `Expresn` can be the name of a column, a function, or an expression. |

#### Return value
Double. Returns an estimate of the standard deviation for `column`.

#### Usage
If you specify `range`, `StDev` returns an estimate for the standard deviation of `column` within `range`. If you specify `DISTINCT`, `StDev` returns an estimate of the standard deviation for the distinct values in `column`, or if you specify `expresn`, the estimate of the standard deviation of the rows in `column` where the value of `expresn` is distinct.
For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data tab page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

**Estimating or calculating actual standard deviation**  
\texttt{StDev} assumes that the values in column are a sample of the values in the rows in the column in the database table. If you selected all the rows in the column in the DataWindow object’s SELECT statement, use \texttt{StDevP} to compute the standard deviation of the population.

**Not in validation rules or filter expressions**  
You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

\textbf{Examples}

These examples all assume that the SELECT statement did not retrieve all the rows in the database table. \texttt{StDev} is intended to work with a subset of rows, which is a sample of the full set of data.

This expression returns an estimate for standard deviation of the values in the column named salary:

\[
\text{StDev}(\text{salary})
\]

This expression returns an estimate for standard deviation of the values in the column named salary in group 1:

\[
\text{StDev}(\text{salary for group 1})
\]

This expression returns an estimate for standard deviation of the values in column 4 on the page:

\[
\text{StDev}(\#4 \text{ for page})
\]

This expression entered in the Value box on the Data tab page in the graph’s property sheet returns an estimate for standard deviation of the values in the qty_used column in the graph:

\[
\text{StDev}(\text{qty_used for graph})
\]
This expression for a computed field in a crosstab returns the estimate for standard deviation of the values in the qty_ordered column in the crosstab:

\[ \text{StDev(qty\_ordered \ for \ crosstab)} \]

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the estimated standard deviation of the order amount for the distinct order numbers:

\[ \text{StDev(order\_amt \ for \ all \ DISTINCT \ order\_nbr)} \]

See also
StDevP
Var

**StDevP**

**Description**
Calculates the standard deviation for the specified column. Standard deviation is a measurement of how widely values vary from average.

**Syntax**

\[ \text{StDevP ( column \{ FOR \ range \{ DISTINCT \{ expres1 \{, expres2 \{, ... \} \} \} \} \)}} \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{column}</td>
<td>The column for which you want the standard deviation of the values in the rows. Column can be the column name or the column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. The datatype of \text{column} must be numeric.</td>
</tr>
<tr>
<td>\text{FOR range}</td>
<td>The data to be included in the standard deviation. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>• ALL – (Default) The standard deviation for all values in \text{column}.</td>
</tr>
<tr>
<td></td>
<td>• GROUP \text{n} – The standard deviation for values in \text{column} in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>• PAGE – The standard deviation for the values in \text{column} on a page.</td>
</tr>
<tr>
<td></td>
<td>For Crosstabs, specify CROSSTAB for range to indicate the standard deviation for all values in \text{column} in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph objects specify GRAPH and for OLE objects specify OBJECT to indicate the standard deviation for values in \text{column} in the range specified for the Rows option.</td>
</tr>
</tbody>
</table>
**StDevP**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISTINCT</td>
<td>Causes StDevP to consider only the distinct values in column when determining the standard deviation. For a value of column, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>expresn</td>
<td>One or more expressions that you want to evaluate to determine distinct rows. Expresn can be the name of a column, a function, or an expression.</td>
</tr>
</tbody>
</table>

**Return value**

Double. Returns the standard deviation for column.

**Usage**

If you specify range, StDevP returns the standard deviation for column within range. If you specify DISTINCT, StDevP returns an estimate of the standard deviation for the distinct values in column, or if you specify expresn, the estimate of the standard deviation of the rows in column where the value of expresn is distinct.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data tab page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

**Estimating or calculating actual standard deviation**

StDevP assumes that the values in column are the values in all the rows in the column in the database table. If you did not select all rows in the column in the SELECT statement, use StDev to compute an estimate of the standard deviation of a sample.

**Not in validation rules or filter expressions**

You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.
Examples

These examples all assume that the SELECT statement retrieved all rows in the database table. StDevP is intended to work with a full set of data, not a subset.

This expression returns the standard deviation of the values in the column named salary:

\[ \text{StDevP(salary)} \]

This expression returns the standard deviation of the values in group 1 in the column named salary:

\[ \text{StDevP(salary for group 1)} \]

This expression returns the standard deviation of the values in column 4 on the page:

\[ \text{StDevP(#4 for page)} \]

This expression entered in the Value box on the Data tab page in the graph’s property sheet returns the standard deviation of the values in the qty_ordered column in the graph:

\[ \text{StDevP(qty_ordered for graph)} \]

This expression for a computed field in a crosstab returns the standard deviation of the values in the qty_ordered column in the crosstab:

\[ \text{StDevP(qty_ordered for crosstab)} \]

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the standard deviation of the order amount for the distinct order numbers:

\[ \text{StDevP(order_amt for all DISTINCT order_nbr)} \]

StDev
VarP

String

Description

Formats data as a string according to a specified display format mask. You can convert and format date, DateTime, numeric, and time data. You can also apply a display format to a string.
String

Syntax

\[
\text{String ( data }, \text{ format } \text{ )}
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>The data you want returned as a string with the specified formatting. Data can have a date, DateTime, numeric, time, or string datatype.</td>
</tr>
<tr>
<td>format</td>
<td>A string of the display masks you want to use to format the data. The masks consist of formatting information specific to the datatype of data. If data is type string, format is required. The format string can consist of more than one mask, depending on the datatype of data. Each mask is separated by a semicolon. See Usage for details on each datatype.</td>
</tr>
</tbody>
</table>

Return value

String. Returns data in the specified format if it succeeds and the empty string ("") if the datatype of data does not match the type of display mask specified or format is not a valid mask.

Usage

For date, DateTime, numeric, and time data, the system’s default format is used for the returned string if you do not specify a format. For numeric data, the default format is the [General] format.

For string data, a display format mask is required. (Otherwise, the function would have nothing to do.)

The format can consist of one or more masks:

- Formats for date, DateTime, string, and time data can include one or two masks. The first mask is the format for the data; the second mask is the format for a null value.

- Formats for numeric data can have up to four masks. A format with a single mask handles both positive and negative data. If there are additional masks, the first mask is for positive values, and the additional masks are for negative, zero, and null values.

A format can include color specifications.

If the display format does not match the datatype, the attempt to apply the mask produces unpredictable results.

For information on specifying display formats, see the Users Guide.

When you use String to format a date and the month is displayed as text (for example, when the display format includes “mmm”), the month is in the language of the deployment files available when the application is run. If you have installed localized files in the development environment or on a user’s machine, then on that machine the month in the resulting string will be in the language of the localized files.
For information about localized deployment files, see the chapter on internationalizing an application in *Application Techniques*.

### Examples

This expression returns Jan 31, 2005:

```powerscript
String(2005-01-31, "mmm dd, yyyy")
```

This expression returns Jan 31, 2005 6 hrs and 8 min:

```powerscript
String(2005-01-31 06:08:00, 'mmm dd, yyyy, h "hrs
and" m "min"')
```

This expression:

```powerscript
String(nbr, "0000;(000);****;empty")
```
returns:

- 0123 if `nbr` is 123
- 123 if `nbr` is -123
- **** if `nbr` is 0
- empty if `nbr` is null

This expression returns A-B-C:

```powerscript
String("ABC", "@-@-@")
```

This expression returns A*B:

```powerscript
String("ABC", "@*@")
```

This expression returns ABC:

```powerscript
String("ABC", "@@@")
```

This expression returns a space:

```powerscript
String("ABC", " ")
```

This expression returns 6 hrs and 8 min:

```powerscript
String(06:08:02,'h "hrs and" m "min"')
```

This expression returns 08:06:04 pm:

```powerscript
String(20:06:04, "hh:mm:ss am/pm")
```

This expression returns 8:06:04 am:

```powerscript
String(08:06:04, "h:mm:ss am/pm")
```

This expression returns 6:11:25.30000:

```powerscript
String(6:11:25.300000, "h:mm:ss.fffffff")
```

String in the *PowerScript Reference*
StripRTF

Description
Removes the rich text formatting from the specified column.

Syntax
StripRTF ( string )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The column to be stripped of rich text formatting.</td>
</tr>
</tbody>
</table>

Examples
This expression is used in a compute field expression to remove the formatting from a rich text edit column and display plain text in the compute field.

```
StripRTF(rte_description)
```

Sum

Description
Calculates the sum of the values in the specified column.

Syntax
Sum ( column { FOR range { DISTINCT { expres1 {, expres2 {, ... } } } } } )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>The column for which you want the sum of the data values. Column can be the column name or the column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. The datatype of column must be numeric.</td>
</tr>
</tbody>
</table>
| range (optional) | The data to be included in the sum. For most presentation styles, values for range are:
| ALL – (Default) The sum of all values in column. |
| GROUP n – The sum of values in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1. |
| PAGE – The sum of the values in column on a page. |

For Crosstabs, specify CROSSTAB for range:
| CROSSTAB – (Crosstabs only) The sum of all values in column in the crosstab. |

For Graph and OLE objects, specify one of the following:
| GRAPH – (Graphs only) The sum of values in column in the range specified for the Rows option of the graph. |
| OBJECT – (OLE objects only) The sum of values in column in the range specified for the Rows option of the OLE object. |
DataWindow Expression Functions

Return value

The appropriate numeric datatype. Returns the sum of the data values in column.

Usage

If you specify range, Sum returns the sum of the values in column within range. If you specify DISTINCT, Sum returns the sum of the distinct values in column, or if you specify expresn, the sum of the values of column where the value of expresn is distinct.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Null values are ignored and are not included in the calculation.

Not in validation rules or filter expressions

You cannot use this or other aggregate functions in validation rules or filter expressions.

Examples

This expression returns the sum of the values in group 1 in the column named salary:

\[ \text{Sum}(\text{salary for group 1}) \]

This expression returns the sum of the values in column 4 on the page:

\[ \text{Sum}(#4 \text{ for page}) \]
Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the sum of the order amount for the distinct order numbers:

\[
\text{Sum}(\text{order_amt for all DISTINCT order_nbr})
\]

“Example 1: counting null values in a column” on page 19
“Example 2: counting male and female employees” on page 21

## Tan

**Description**
Calculates the tangent of an angle.

**Syntax**

\[
\text{Tan}(n)
\]

**Argument** | **Description**
--- | ---
\(n\) | The angle (in radians) for which you want the tangent

**Return value**
Double. Returns the tangent of \(n\) if it succeeds and –1 if an error occurs.

**Examples**
Both these expressions return 0:

\[
\begin{align*}
\text{Tan}(0) \\
\text{Tan}(\text{Pi}(1))
\end{align*}
\]

This expression returns 1.55741:

\[
\text{Tan}(1)
\]

**See also**
Cos
Pi
Sin
Tan in the *PowerScript Reference*
### Time

**Description**
Converts a string to a time datatye.

**Syntax**
```
Time ( string )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>A string containing a valid time (such as 8 AM or 10:25) that you want returned as a time datatye. Only the hour is required; you do not have to include the minutes, seconds, or microseconds of the time or AM or PM. The default value for minutes and seconds is 00 and for microseconds is 000000. AM or PM is determined automatically.</td>
</tr>
</tbody>
</table>

**Return value**
Time. Returns the time in `string` as a time datatye. If `string` does not contain a valid time, `Time` returns 00:00:00.

**Examples**
This expression returns the time datatye for 45 seconds before midnight (23:59:15):
```
Time("23:59:15")
```

This expression for a computed field returns the value in the time_received column as a value of type time if time_received is not the empty string. Otherwise, it returns 00:00:00:
```
If(time_received = "", 00:00:00,
   Time(time_received))
```

This example is similar to the previous one, except that it returns 00:00:00 if time_received contains a null value:
```
If(IsNull(time_received), 00:00:00,
   Time(time_received))
```

**See also**
Time in the PowerScript Reference

### Today

**Description**
Obtains the system date and time.

**Syntax**
```
Today ( )
```

**Return value**
DateTime. Returns the current system date and time.

**Usage**
To display both the date and the time, a computed field must have a display format that includes the time.
The PowerScript and DataWindow painter versions of the Today function have different datatypes. The return value of the PowerScript Today function is date.

Examples

This expression for a computed field displays the date and time when the display format for the field is "mm/dd/yy hh:mm":

\[ \text{Today}() \]

See also

Now
Today in the PowerScript Reference

---

**Trim**

Description

Removes leading and trailing spaces from a string.

Syntax

\[ \text{Trim} \left( \text{string} \right) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want returned with leading and trailing spaces deleted</td>
</tr>
</tbody>
</table>

Return value

String. Returns a copy of string with all leading and trailing spaces deleted if it succeeds and the empty string ("") if an error occurs.

Usage

Trim is useful for removing spaces that a user might have typed before or after newly entered data.

Examples

This expression returns BABE RUTH:

\[ \text{Trim} \left( \text{" BABE RUTH "} \right) \]

See also

LeftTrim
RightTrim
Trim in the PowerScript Reference

---

**Truncate**

Description

Truncates a number to the specified number of decimal places.

Syntax

\[ \text{Truncate} \left( x, n \right) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>The number you want to truncate.</td>
</tr>
<tr>
<td>n</td>
<td>The number of decimal places to which you want to truncate x. Valid values are 0 through 28.</td>
</tr>
</tbody>
</table>
Return value

The datatype of x. If n is positive, returns x truncated to the specified number of decimal places. If n is negative, returns x truncated to \((- n +1\) places before the decimal point. Returns -1 if it fails.

Examples

This expression returns 9.2:

\texttt{Truncate}(9.22, 1)

This expression returns 9.2:

\texttt{Truncate}(9.28, 1)

This expression returns 9:

\texttt{Truncate}(9.9, 0)

This expression returns -9.2:

\texttt{Truncate}(-9.29, 1)

This expression returns 0:

\texttt{Truncate}(9.2, -1)

This expression returns 50:

\texttt{Truncate}(54, -1)

See also

Ceiling
Int
Round
Truncate in the PowerScript Reference

**Upper**

Description

Converts all characters in a string to uppercase letters.

Syntax

\texttt{Upper ( string )}

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>The string you want to convert to uppercase letters</td>
</tr>
</tbody>
</table>

Return value

String. Returns string with lowercase letters changed to uppercase if it succeeds and the empty string (""") if an error occurs.

Examples

This expression returns BABE RUTH:

\texttt{Upper("Babe Ruth")}
Var

Description
Calculates an estimate of the variance for the specified column. The variance is the square of the standard deviation.

Syntax
Var ( column | FOR range | DISTINCT { expres1 | expres2 | ... } )

Argument | Description
--- | ---
column | The column for which you want an estimate for the variance of the values in the rows. Column can be the column name or the column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. The datatype of column must be numeric.

FOR range (optional) | The data to be included in the estimate of the variance. For most presentation styles, values for range are:

- **ALL** – (Default) The estimate of the variance for all rows in column.
- **GROUP n** – The estimate of the variance for rows in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.
- **PAGE** – The estimate of the variance for the rows in column on a page.

For Crosstabs, specify CROSSTAB for range:

- **CROSSTAB** – (Crosstabs only) The estimate of the variance for all rows in column in the crosstab.

For Graph and OLE objects, specify one of the following:

- **GRAPH** – (Graphs only) The estimate of the variance for rows in column in the range specified for the Rows option.
- **OBJECT** – (OLE objects only) The estimate of the variance for rows in column in the range specified for the Rows option.

DISTINCT (optional) | Causes Var to consider only the distinct values in column when determining the variance. For a value of column, the first row found with the value is used and other rows that have the same value are ignored.

expresn (optional) | One or more expressions that you want to evaluate to determine distinct rows. Expresn can be the name of a column, a function, or an expression.
Return value

Double or decimal if the arguments are decimal. Returns an estimate for the variance for column. If you specify group, Var returns an estimate for the variance for column within group.

Usage

If you specify range, Var returns an estimate for the variance for column within range. If you specify DISTINCT, Var returns the variance for the distinct values in column, or if you specify exprens, the estimate for the variance of the rows in column where the value of exprens is distinct.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range.

Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

Estimating variance or calculating actual variance

Var assumes that the values in column are a sample of the values in rows in the column in the database table. If you select all rows in the column in the SELECT statement, use VarP to compute the variance of a population.

Not in validation rules or filter expressions

You cannot use this or other aggregate functions in validation rules or filter expressions.

Examples

These examples all assume that the SELECT statement did not retrieve all of the rows in the database table. Var is intended to work with a subset of rows, which is a sample of the full set of data.

This expression returns an estimate for the variance of the values in the column named salary:

\[ \text{Var}(\text{salary}) \]
VarP

This expression returns an estimate for the variance of the values in the column named salary in group 1:

\[ \text{Var}(\text{salary for group 1}) \]

This expression entered in the Value box on the Data property page in the graph’s property sheet returns an estimate for the variance of the values in the quantity column in the graph:

\[ \text{Var}(\text{quantity for graph}) \]

This expression for a computed field in a crosstab returns an estimate for the variance of the values in the quantity column in the crosstab:

\[ \text{Var}(\text{quantity for crosstab}) \]

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the estimate for the variance of the order amount for the distinct order numbers:

\[ \text{Var}(\text{order_amt for all DISTINCT order_nbr}) \]

See also
StDev
VarP

VarP

Description
Calculates the variance for the specified column. The variance is the square of the standard deviation.

Syntax
\[ \text{VarP} \left( \text{column} \{ \text{FOR range} \{ \text{DISTINCT } \{ \text{expres1}, \text{expres2}, \ldots \} \} \} \right) \]

Argument | Description
---|---
column | The column for which you want the variance of the values in the rows. Column can be the column name or the column number preceded by a pound sign (#). Column can also be an expression that includes a reference to the column. The datatype of column must be numeric.
Return value
Double or decimal if the arguments are decimal. Returns the variance for column. If you specify group, Var returns the variance for column within range.

Usage
If you specify range, Var returns the variance for column within range. If you specify DISTINCT, Var returns the variance for the distinct values in column, or if you specify expresn, the variance of the rows in column where the value of expresn is distinct.

For graphs and OLE objects, you do not select the range when you call the function. The range has already been determined by the Rows setting on the Data property page (the Range property), and the aggregation function uses that range. Settings for Rows include the following:

- For the Graph or OLE presentation style, Rows is always All.
- For Graph controls, Rows can be All, Page, or Group.
- For OLE controls, Rows can be All, Current Row, Page, or Group. The available choices depend on the layer the control occupies.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR range</td>
<td>The data that will be included in the variance. For most presentation styles, values for range are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>- ALL – (Default) The variance for all rows in column.</td>
</tr>
<tr>
<td></td>
<td>- GROUP n – The variance for rows in column in the specified group. Specify the keyword GROUP followed by the group number: for example, GROUP 1.</td>
</tr>
<tr>
<td></td>
<td>- PAGE – The variance for the rows in column on a page.</td>
</tr>
<tr>
<td></td>
<td>For Crosstabs, specify CROSSTAB for range:</td>
</tr>
<tr>
<td></td>
<td>- CROSSTAB – (Crosstabs only) The variance for all rows in column in the crosstab.</td>
</tr>
<tr>
<td></td>
<td>For Graph and OLE objects, specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>- GRAPH – (Graphs only) The variance for rows in column in the range specified for the Rows option.</td>
</tr>
<tr>
<td></td>
<td>- OBJECT – (OLE objects only) The variance for rows in column in the range specified for the Rows option.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Causes Var to consider only the distinct values in column when determining the variance. For a value of column, the first row found with the value is used and other rows that have the same value are ignored.</td>
</tr>
<tr>
<td>(optional)</td>
<td>expresn</td>
</tr>
</tbody>
</table>
**Estimating variance or calculating actual variance**
VarP assumes that the values in column are the values in all rows in the column in the database table. If you did not select all the rows in the column in the SELECT statement, use Var to compute an estimate of the variance of a sample.

**Not in validation rules or filter expressions**
You cannot use this or other aggregate functions in validation rules or filter expressions.

Using an aggregate function cancels the effect of setting Retrieve Rows As Needed in the painter. To do the aggregation, a DataWindow object always retrieves all rows.

These examples all assume that the SELECT statement retrieved all rows in the database table. VarP is intended to work with a full set of data, not a subset.

This expression returns the variance of the values in the column named salary:

```
VarP(salary)
```

This expression returns the variance of the values in group 1 in the column named salary:

```
VarP(salary for group 1)
```

This expression returns the variance of the values in column 4 on the page:

```
VarP(#4 for page)
```

This expression entered in the Value box on the Data property page in the graph’s property sheet returns the variance of the values in the quantity column in the graph:

```
VarP(quantity for graph)
```

This expression for a computed field in a crosstab returns the variance of the values in the quantity column in the crosstab:

```
VarP(quantity for crosstab)
```

Assuming a DataWindow object displays the order number, amount, and line items for each order, this computed field returns the variance of the order amount for the distinct order numbers:

```
VarP(order_amt for all DISTINCT order_nbr)
```

**See also**
StDevP
Var

150  PowerBuilder
**WordCap**

**Description**
Sets the first letter of each word in a string to a capital letter and all other letters to lowercase (for example, ROBERT E. LEE would be Robert E. Lee).

**Syntax**

```
WordCap ( string )
```

**Argument** | **Description**
--- | ---
`string` | A string or expression that evaluates to a string that you want to display with initial capital letters (for example, Monday Morning)

**Return value**
String. Returns `string` with the first letter of each word set to uppercase and the remaining letters lowercase if it succeeds, and null if an error occurs.

**Examples**
This expression returns Boston, Massachusetts:

```
WordCap("boston, MASSACHUSETTS")
```

This expression concatenates the characters in the `emp_fname` and `emp_lname` columns and makes the first letter of each word uppercase:

```
WordCap(emp_fname + " " + emp_lname)
```

---

**Year**

**Description**
Gets the year of a date value.

**Syntax**

```
Year ( date )
```

**Argument** | **Description**
--- | ---
`date` | The date value from which you want the year

**Return value**
Integer. Returns an integer whose value is a 4-digit year adapted from the year portion of `date` if it succeeds and 1900 if an error occurs.

If the year is two digits, then the century is set as follows. If the year is between 00 to 49, the first two digits are 20; if the year is between 50 and 99, the first two digits are 19.

**Usage**
Obtains the year portion of `date`. Years from 1000 to 3000 inclusive are handled.

If your data includes dates before 1950, such as birth dates, always specify a 4-digit year so that `Year` (and other functions, such as `Sort`) interpret the date as intended.
**Regional settings**
To make sure you get correct return values for the year, you must verify that yyyy is the Short Date Style for year in the Regional Settings of the user’s Control Panel. Your program can check this with the RegistryGet function.

If the setting is not correct, you can ask the user to change it manually or to have the application change it (by calling the RegistrySet function). The user might need to reboot after the setting is changed.

**Examples**

This expression returns 2005:

\[
\text{Year}(2005-01-31)
\]

CHAPTER 3  DataWindow Object Properties

About this chapter
This chapter describes the properties that control the appearance and behavior of a DataWindow object.

Overview of DataWindow object properties

DataWindow object properties apply to the DataWindow object itself, not to the DataWindow control or DataStore that contains it. There are several ways you can affect the values of DataWindow object properties at runtime:

- Use the general-purpose Describe and Modify methods to get and set property values.
- Use methods that get and set specific properties.
- Use methods that get and set specific properties.
- For many properties, enter expressions in the painter that set properties conditionally at runtime.
- You can use the SyntaxFromSQL method on a transaction object to generate DataWindow source code that sets some DataWindow properties. You can use the generated code in the Create method to create new DataWindows.
Overview of DataWindow object properties

Summary tables in the first part of this chapter

The tables in “Controls in a DataWindow and their properties” on page 155 list the properties for each control within a DataWindow object, with short descriptions. There are also tables for SyntaxFromSql object keywords. After the first table of DataWindow properties, the tables are alphabetical by control and keyword name.

The tables include check mark columns that identify whether you can use that property with Modify (M) or SyntaxFromSql (S). When (exp) is included in the description, you can specify a DataWindow expression as the value for that property. A DataWindow expression lets you specify conditions for determining the property value.

You can get the value of all properties in all tables

At runtime, you can use Describe or dot notation to get the value of all properties listed in all tables.

Alphabetical reference list in the second part of this chapter

The second half of this chapter is an alphabetical list of properties with descriptions, syntax, and examples. When you find a property you want to use in the first part, look up the property in the alphabetical list to find the specific syntax you need to use. In the tables that describe the property values, (exp) again indicates that you can use a DataWindow expression for the value.

Accessing properties in different DataWindow environments

The property reference has syntax for Describe and Modify and for PowerBuilder dot notation.

In the DataWindow Web control for ActiveX, you must use Describe and Modify to access property values.

Examples and quoted strings

The only examples given are PowerBuilder examples. However, the arguments for Describe and Modify are quoted strings that are generally valid in all environments. If the strings include nested quotes, see “Nested strings and special characters for DataWindow object properties” on page 446 for information on the appropriate escape character in each environment.

For more information and examples of setting properties, see:

- Chapter 5, “Accessing DataWindow Object Properties in Code”
- Describe and Modify methods in Chapter 9, “Methods for the DataWindow Control”
- SyntaxFromSql method in the PowerScript Reference
Controls in a DataWindow and their properties

The tables in this section list the properties that apply to DataWindow objects and SyntaxFromSql (Group, Style, and Title) keywords.

### Topic for DataWindow objects and keywords

### Properties for the DataWindow object

An x in the M (Modify) column means you can change the property. An x in the S column means you can use the property with the SyntaxFromSql method. When \((exp)\) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>

### Properties for Button controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a Button</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccessibleDescription</td>
<td>x</td>
<td>A description of the control for use by assistive technology tools.</td>
</tr>
<tr>
<td>AccessibleName</td>
<td>x</td>
<td>A descriptive label for the control.</td>
</tr>
<tr>
<td>AccessibleRole</td>
<td>x</td>
<td>A description of the kind of user-interface element that the control is.</td>
</tr>
</tbody>
</table>

---

**Summary.property**: Color, height, and so on for the summary band.

**Syntax**: The syntax of the DataWindow.

**Syntax.Data**: The data of the DataWindow in parse format.

**Syntax.Modified**: Whether the syntax has been modified.

**Table.property**: Various settings for the database.

**Table.sqlaction.property**: Stored procedures for update activity.

**Timer_Interval**: The milliseconds between timer events.

**Transparency (DataWindow objects)**: Setting that controls the transparency of the background/primary gradient color.

**Trailer.#.property**: Color, height, and so on for a group’s trailer band.

**Tree.property**: Settings for a TreeView DataWindow.

**Tree.Leaf.TreeNodeIconName**: The file name of the tree node icon in the detail band of a TreeView DataWindow.

**Tree.Level.#.property**: The file name of the icon for a TreeView node in a TreeView level band when the icon is in either the expanded or collapsed state.

**Units**: The unit of measure for the DataWindow.

**VerticalScrollMaximum**: The height of the scroll box in the scroll bar.

**VerticalScrollPosition**: The position of the scroll box in the scroll bar.

**XHTMLGen.Browser**: A string that identifies the browser in which XHTML generated within an XSLT style sheet is displayed.

**XMLGen.property**: Settings that specify the physical path to which XML is published and the URL referenced by the JavaScript that transforms the XML to XHTML.

**XSLTGen.property**: Settings that specify the physical path to which the generated XSLT style sheet is published and the URL referenced by the JavaScript that transforms the XML to XHTML.

**Zoom**: The scaling percentage of the DataWindow.

<tr>
<td>Y</td>
<td>x</td>
<td>(exp) The y coordinate of the button control.</td>
</tr>
</tbody>
</table>
## Properties for Column controls in DataWindow objects

An x in the M (Modify) column means you can change the property. An x in the S column means you can use the property with the `SyntaxFromSQL` method. When `(exp)` is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a Column</th>
<th>M</th>
<th>S</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccessibleDescription</td>
<td>x</td>
<td></td>
<td>A description of the control for use by assistive technology tools.</td>
</tr>
<tr>
<td>AccessibleName</td>
<td>x</td>
<td></td>
<td>A descriptive label for the control.</td>
</tr>
<tr>
<td>AccessibleRole</td>
<td></td>
<td></td>
<td>A description of the kind of user-interface element that the control is.</td>
</tr>
<tr>
<td>Accelerator</td>
<td>x</td>
<td></td>
<td><code>(exp)</code> The accelerator key for the column.</td>
</tr>
<tr>
<td>Alignment</td>
<td>x</td>
<td></td>
<td><code>(exp)</code> The alignment of the column’s text.</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
<td></td>
<td>A list of the properties of the column.</td>
</tr>
<tr>
<td>Background.property</td>
<td>x</td>
<td>x</td>
<td><code>(exp)</code> Background settings for the column.</td>
</tr>
<tr>
<td>Band</td>
<td></td>
<td></td>
<td>The band containing the column.</td>
</tr>
<tr>
<td>BitmapName</td>
<td></td>
<td></td>
<td>Whether the column’s content names a picture that will be displayed instead of the text.</td>
</tr>
<tr>
<td>Border</td>
<td>x</td>
<td>x</td>
<td><code>(exp)</code> The type of border around the column.</td>
</tr>
<tr>
<td>CheckBox.property</td>
<td>x</td>
<td></td>
<td>Settings for CheckBox edit style.</td>
</tr>
<tr>
<td>Color</td>
<td>x</td>
<td>x</td>
<td><code>(exp)</code> The text color.</td>
</tr>
<tr>
<td>ColType</td>
<td></td>
<td></td>
<td>The column’s datatype.</td>
</tr>
<tr>
<td>Criteria.property</td>
<td>x</td>
<td></td>
<td>Settings for column in Prompt for Criteria dialog box.</td>
</tr>
<tr>
<td>dbAlias</td>
<td>x</td>
<td></td>
<td>An alias for the name of the database column.</td>
</tr>
<tr>
<td>dbName</td>
<td>x</td>
<td></td>
<td>The name of the database column.</td>
</tr>
<tr>
<td>dddw.property</td>
<td>x</td>
<td></td>
<td>Settings for DropDownListDataWindow edit style.</td>
</tr>
<tr>
<td>ddlb.property</td>
<td>x</td>
<td></td>
<td>Settings for DropDownListBox edit style.</td>
</tr>
<tr>
<td>Edit.property</td>
<td>x</td>
<td>x</td>
<td>Settings for Edit edit style.</td>
</tr>
<tr>
<td>EditMask.property</td>
<td>x</td>
<td></td>
<td>Settings for EditMask edit style.</td>
</tr>
<tr>
<td>Font.property</td>
<td>x</td>
<td>x</td>
<td><code>(exp)</code> Font settings for the column text.</td>
</tr>
<tr>
<td>Format</td>
<td>x</td>
<td></td>
<td><code>(exp)</code> The column’s display format.</td>
</tr>
<tr>
<td>Height</td>
<td>x</td>
<td></td>
<td><code>(exp)</code> The height of the column.</td>
</tr>
<tr>
<td>Height.AutoScale</td>
<td>x</td>
<td></td>
<td>Whether column height is adjusted to fit the data.</td>
</tr>
<tr>
<td>HideSnaked</td>
<td>x</td>
<td></td>
<td>Whether the control appears once per page when printing newspaper columns.</td>
</tr>
<tr>
<td>HTML..property</td>
<td>x</td>
<td></td>
<td><code>(exp)</code> Settings for creating hyperlinks for column data.</td>
</tr>
<tr>
<td>Identity</td>
<td>x</td>
<td></td>
<td>Whether the DBMS sets the column’s value.</td>
</tr>
<tr>
<td>ID</td>
<td></td>
<td></td>
<td>The number of the column.</td>
</tr>
<tr>
<td>Ink.property</td>
<td>x</td>
<td></td>
<td>Settings for Ink attributes of the InkEdit edit style.</td>
</tr>
<tr>
<td>InkEdit.property</td>
<td>x</td>
<td></td>
<td>Settings for InkEdit edit style.</td>
</tr>
</tbody>
</table>
### Controls in a DataWindow and their properties

<table>
<thead>
<tr>
<th>Property for a Column</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial</td>
<td>x</td>
<td>The initial value in the column for a new row.</td>
</tr>
<tr>
<td>Key</td>
<td>x</td>
<td>Whether column is part of the table's primary key.</td>
</tr>
<tr>
<td>Moveable</td>
<td>x</td>
<td>Whether the user can move the column.</td>
</tr>
<tr>
<td>Name</td>
<td></td>
<td>The name of the column.</td>
</tr>
<tr>
<td>Pointer</td>
<td>x</td>
<td><em>(exp)</em> The pointer's image when it is over the column.</td>
</tr>
<tr>
<td>Protect</td>
<td>x</td>
<td><em>(exp)</em> Whether the column is protected from changes.</td>
</tr>
<tr>
<td>RadioButtons.property</td>
<td>x</td>
<td>Settings for RadioButton edit style.</td>
</tr>
<tr>
<td>Resizeable</td>
<td>x</td>
<td>Whether the user can resize the column.</td>
</tr>
<tr>
<td>RichEdit.property</td>
<td>x</td>
<td>Settings for RichText edit style.</td>
</tr>
<tr>
<td>SlideLeft</td>
<td>x</td>
<td><em>(exp)</em> Whether the column moves left to fill in space.</td>
</tr>
<tr>
<td>SlideUp</td>
<td>x</td>
<td><em>(exp)</em> How the column moves up to fill in space.</td>
</tr>
<tr>
<td>TabSequence</td>
<td>x</td>
<td>The position of the column in the tab order.</td>
</tr>
<tr>
<td>Tag</td>
<td>x</td>
<td><em>(exp)</em> The tag text for the column.</td>
</tr>
<tr>
<td>Type</td>
<td></td>
<td>The control’s type, which is Column.</td>
</tr>
<tr>
<td>Update</td>
<td>x</td>
<td>Whether the column is updatable.</td>
</tr>
<tr>
<td>Validation</td>
<td>x</td>
<td><em>(exp)</em> The validation expression for the column.</td>
</tr>
<tr>
<td>ValidationMsg</td>
<td>x</td>
<td><em>(exp)</em> The message displayed when validation fails.</td>
</tr>
<tr>
<td>Values (for columns)</td>
<td>x</td>
<td>The values in the column’s code table.</td>
</tr>
<tr>
<td>Visible</td>
<td>x</td>
<td><em>(exp)</em> Whether the column control is visible.</td>
</tr>
<tr>
<td>Width</td>
<td>x</td>
<td><em>(exp)</em> The width of the column.</td>
</tr>
<tr>
<td>X</td>
<td>x</td>
<td><em>(exp)</em> The x coordinate of the column.</td>
</tr>
<tr>
<td>Y</td>
<td></td>
<td><em>(exp)</em> The y coordinate of the column.</td>
</tr>
</tbody>
</table>

### Properties for Computed Field controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When *(exp)* is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a computed field</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccessibleDescription</td>
<td>x</td>
<td>A description of the control for use by assistive technology tools.</td>
</tr>
<tr>
<td>AccessibleName</td>
<td>x</td>
<td>A descriptive label for the control.</td>
</tr>
<tr>
<td>AccessibleRole</td>
<td></td>
<td>A description of the kind of user-interface element that the control is.</td>
</tr>
<tr>
<td>Alignment</td>
<td>x</td>
<td><em>(exp)</em> The alignment of the computed field’s text.</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
<td>A list of the properties of the computed field.</td>
</tr>
<tr>
<td>Background.property</td>
<td>x</td>
<td><em>(exp)</em> Background settings for the computed field.</td>
</tr>
<tr>
<td>Band</td>
<td></td>
<td>The band containing the computed field.</td>
</tr>
<tr>
<td>Border</td>
<td>x</td>
<td><em>(exp)</em> The type of border around the computed field.</td>
</tr>
</tbody>
</table>
Properties for Graph controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a Graph</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccessibleDescription</td>
<td>x</td>
<td>A description of the control for use by assistive technology tools.</td>
</tr>
<tr>
<td>AccessibleName</td>
<td>x</td>
<td>A descriptive label for the control.</td>
</tr>
<tr>
<td>AccessibleRole</td>
<td></td>
<td>A description of the kind of user-interface element that the control is.</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
<td>A list of the properties of the graph.</td>
</tr>
<tr>
<td>Axis</td>
<td>x</td>
<td>(exp) List of items (categories, series, or values) for the axis.</td>
</tr>
<tr>
<td>Axis.property</td>
<td>x</td>
<td>(exp) Properties for a graph axis.</td>
</tr>
<tr>
<td>AxisDispAttr</td>
<td>x</td>
<td>(exp) Display properties for an axis (see DispAttr.fontproperty in this table).</td>
</tr>
<tr>
<td>BackColor</td>
<td>x</td>
<td>(exp) The background color of the graph.</td>
</tr>
</tbody>
</table>
### Property for a Graph

<table>
<thead>
<tr>
<th>Property for a Graph</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Band</td>
<td></td>
<td>The band containing the graph.</td>
</tr>
<tr>
<td>Border</td>
<td>x</td>
<td>(exp) The type of border around the graph.</td>
</tr>
<tr>
<td>Category</td>
<td>x</td>
<td>(exp) List of categories for the axis (see Axis in this table).</td>
</tr>
<tr>
<td>Category.property</td>
<td>x</td>
<td>(exp) Properties for the Category axis (see Axis.property in this table).</td>
</tr>
<tr>
<td>Category.DispAttr</td>
<td>x</td>
<td>(exp) Display properties for the Category axis (see DispAttr.fontproperty in this table).</td>
</tr>
<tr>
<td>Color</td>
<td>x</td>
<td>(exp) The text color.</td>
</tr>
<tr>
<td>Depth</td>
<td>x</td>
<td>(exp) The depth of a 3D graph.</td>
</tr>
<tr>
<td>DispAttr.fontproperty</td>
<td>x</td>
<td>Font settings for various components of the graph.</td>
</tr>
<tr>
<td>Elevation</td>
<td>x</td>
<td>(exp) The elevation of a 3D graph.</td>
</tr>
<tr>
<td>GraphType</td>
<td>x</td>
<td>(exp) The type of graph (pie, bar, and so on).</td>
</tr>
<tr>
<td>Height</td>
<td>x</td>
<td>(exp) The height of the graph.</td>
</tr>
<tr>
<td>HideSnaked</td>
<td>x</td>
<td>Whether the control appears once per page when printing newspaper columns.</td>
</tr>
<tr>
<td>Legend</td>
<td>x</td>
<td>(exp) The location of the legend.</td>
</tr>
<tr>
<td>Legend.DispAttr.fontproperty</td>
<td>x</td>
<td>Display properties for the legend.</td>
</tr>
<tr>
<td>Moveable</td>
<td>x</td>
<td>Whether the user can move the graph.</td>
</tr>
<tr>
<td>Name</td>
<td></td>
<td>The name of the graph control.</td>
</tr>
<tr>
<td>OverlapPercent</td>
<td>x</td>
<td>(exp) The overlap between data markers in different series.</td>
</tr>
<tr>
<td>Perspective</td>
<td>x</td>
<td>(exp) The distance of the graph from the front of the window.</td>
</tr>
<tr>
<td>Pie.DispAttr.fontproperty</td>
<td>x</td>
<td>Display properties for the pie slice labels.</td>
</tr>
<tr>
<td>PlotNullData</td>
<td>x</td>
<td>Whether a continuous line is drawn in a line graph when there is no data.</td>
</tr>
<tr>
<td>Pointer</td>
<td>x</td>
<td>(exp) The pointer image when it is over the graph.</td>
</tr>
<tr>
<td>Range</td>
<td></td>
<td>The rows in the DataWindow that are included in the graph.</td>
</tr>
<tr>
<td>Render3D</td>
<td>x</td>
<td>Whether the graph is rendered in the DirectX 3D style.</td>
</tr>
<tr>
<td>Resizeable</td>
<td>x</td>
<td>Whether the user can resize the graph.</td>
</tr>
<tr>
<td>Rotation</td>
<td>x</td>
<td>(exp) The left-to-right rotation of a 3D graph.</td>
</tr>
<tr>
<td>Series</td>
<td>x</td>
<td>(exp) List of series for the axis (see Axis in the table).</td>
</tr>
<tr>
<td>Series.property</td>
<td>x</td>
<td>(exp) Properties for the Series axis (see Axis.property in this table).</td>
</tr>
<tr>
<td>Series.DispAttr</td>
<td>x</td>
<td>(exp) Display properties for the Series axis (see DispAttr.fontproperty in this table).</td>
</tr>
<tr>
<td>ShadeColor</td>
<td>x</td>
<td>(exp) The color of the back edge for 3D data markers.</td>
</tr>
<tr>
<td>SizeToDisplay</td>
<td>x</td>
<td>(exp) Whether to size the graph to the display area.</td>
</tr>
<tr>
<td>SlideLeft</td>
<td>x</td>
<td>(exp) Whether the graph moves left to fill in empty space.</td>
</tr>
<tr>
<td>SlideUp</td>
<td>x</td>
<td>(exp) How the graph moves up to fill in empty space.</td>
</tr>
<tr>
<td>Spacing</td>
<td>x</td>
<td>(exp) The gap between categories.</td>
</tr>
<tr>
<td>Tag</td>
<td>x</td>
<td>(exp) The tag text for the graph.</td>
</tr>
<tr>
<td>Title</td>
<td>x</td>
<td>(exp) The graph’s title.</td>
</tr>
</tbody>
</table>
CHAPTER 3 DataWindow Object Properties

### Properties for GroupBox controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When *exp* is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a GroupBox</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccessibleDescription</td>
<td>x</td>
<td>A description of the control for use by assistive technology tools.</td>
</tr>
<tr>
<td>AccessibleName</td>
<td>x</td>
<td>A descriptive label for the control.</td>
</tr>
<tr>
<td>AccessibleRole</td>
<td>x</td>
<td>A description of the kind of user-interface element that the control is.</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
<td>A list of the properties of the GroupBox control.</td>
</tr>
<tr>
<td>Band</td>
<td>x</td>
<td>The band containing the GroupBox control.</td>
</tr>
<tr>
<td>Border</td>
<td>x</td>
<td><em>exp</em> Border style: 2 (box), 5 (3D lowered), 6 (3D raised).</td>
</tr>
<tr>
<td>Color</td>
<td>x</td>
<td><em>exp</em> The text color.</td>
</tr>
<tr>
<td>Font.property</td>
<td>x</td>
<td><em>exp</em> Font settings for the text.</td>
</tr>
<tr>
<td>Height</td>
<td>x</td>
<td><em>exp</em> The height of the GroupBox control.</td>
</tr>
<tr>
<td>HideSnaked</td>
<td>x</td>
<td>Whether the GroupBox control appears once per page when printing newspaper columns.</td>
</tr>
<tr>
<td>Moveable</td>
<td>x</td>
<td>Whether the user can move the GroupBox control.</td>
</tr>
<tr>
<td>Name</td>
<td></td>
<td>The name of the GroupBox control.</td>
</tr>
<tr>
<td>Pointer</td>
<td>x</td>
<td><em>exp</em> The pointer image when it is over the GroupBox control.</td>
</tr>
<tr>
<td>Resizeable</td>
<td>x</td>
<td>Whether the user can resize the GroupBox control.</td>
</tr>
<tr>
<td>SlideLeft</td>
<td>x</td>
<td><em>exp</em> Whether the GroupBox control moves left to fill in empty space.</td>
</tr>
<tr>
<td>SlideUp</td>
<td>x</td>
<td><em>exp</em> How the GroupBox control moves up to fill in empty space.</td>
</tr>
<tr>
<td>Tag</td>
<td>x</td>
<td><em>exp</em> The tag text for the GroupBox control.</td>
</tr>
<tr>
<td>Text</td>
<td>x</td>
<td><em>exp</em> The displayed text.</td>
</tr>
</tbody>
</table>
### Controls in a DataWindow and their properties

#### Properties for the Group keyword

You use these properties when generating DataWindow source code with the `SyntaxFromSql` method.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NewPage (Group keywords)</td>
<td>Whether a change in a group column’s value causes a page break.</td>
</tr>
<tr>
<td>ResetPageCount</td>
<td>Whether a new value in a group column restarts page numbering.</td>
</tr>
</tbody>
</table>

#### Properties for InkPicture controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When 
(exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BackImage</td>
<td>The column containing the background image for the InkPicture.</td>
</tr>
<tr>
<td>Band</td>
<td>The band containing the InkPicture.</td>
</tr>
<tr>
<td>Border</td>
<td>(exp) The type of border around the InkPicture.</td>
</tr>
<tr>
<td>Enabled</td>
<td>(exp) Whether the control is enabled.</td>
</tr>
<tr>
<td>Height</td>
<td>(exp) The height of the InkPicture.</td>
</tr>
<tr>
<td>Ink.property</td>
<td>(exp) Attributes of the ink in the InkPicture.</td>
</tr>
<tr>
<td>InkPic.property</td>
<td>(exp) Properties that specify the behavior of the InkPicture.</td>
</tr>
<tr>
<td>KeyClause</td>
<td>(exp) The key clause used when retrieving the blob.</td>
</tr>
<tr>
<td>Moveable</td>
<td>Whether the user can move the InkPicture.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the InkPicture control.</td>
</tr>
<tr>
<td>Pointer</td>
<td>(exp) The pointer image when it is over the InkPicture.</td>
</tr>
<tr>
<td>Resizeable</td>
<td>(exp) Whether the user can resize the InkPicture.</td>
</tr>
<tr>
<td>SlideLeft</td>
<td>(exp) Whether the InkPicture moves left to fill in empty space.</td>
</tr>
<tr>
<td>Table (for InkPicture and TableBlobs)</td>
<td>(exp) The table that contains large binary columns used in the control.</td>
</tr>
<tr>
<td>Tag</td>
<td>(exp) The tag text for the InkPicture.</td>
</tr>
<tr>
<td>Visible</td>
<td>(exp) Whether the InkPicture control is visible.</td>
</tr>
</tbody>
</table>
### Properties for Line controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a Line</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attributes</td>
<td></td>
<td>A list of the properties of the line.</td>
</tr>
<tr>
<td>Background.property</td>
<td>x</td>
<td>(exp) Background settings for the line.</td>
</tr>
<tr>
<td>Band</td>
<td></td>
<td>The band containing the line.</td>
</tr>
<tr>
<td>HideSnaked</td>
<td>x</td>
<td>Whether the control appears once per page when printing newspaper columns.</td>
</tr>
<tr>
<td>Moveable</td>
<td>x</td>
<td>Whether the user can move the line.</td>
</tr>
<tr>
<td>Name</td>
<td></td>
<td>The name of the line control.</td>
</tr>
<tr>
<td>Pen.property</td>
<td>x</td>
<td>(exp) Appearance settings of the line.</td>
</tr>
<tr>
<td>Pointer</td>
<td>x</td>
<td>(exp) The pointer image when it is over the line.</td>
</tr>
<tr>
<td>Resizeable</td>
<td>x</td>
<td>Whether the user can resize the line.</td>
</tr>
<tr>
<td>SlideLeft</td>
<td>x</td>
<td>(exp) Whether the line moves left to fill empty space.</td>
</tr>
<tr>
<td>SlideUp</td>
<td>x</td>
<td>(exp) How the line moves up to fill empty space.</td>
</tr>
<tr>
<td>Tag</td>
<td>x</td>
<td>(exp) The tag text for the line.</td>
</tr>
<tr>
<td>Type</td>
<td></td>
<td>The control’s type, which is Line.</td>
</tr>
<tr>
<td>Visible</td>
<td>x</td>
<td>(exp) Whether the Line control is visible.</td>
</tr>
<tr>
<td>X1, X2</td>
<td>x</td>
<td>(exp) The x coordinate of each end of the line.</td>
</tr>
<tr>
<td>Y1, Y2</td>
<td>x</td>
<td>(exp) The y coordinate of each end of the line.</td>
</tr>
</tbody>
</table>

### Properties for OLE Object controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for OLE Object control</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activation</td>
<td>x</td>
<td>The way the OLE Object control is activated.</td>
</tr>
<tr>
<td>Attributes</td>
<td>x</td>
<td>A list of the properties of the OLE Object control.</td>
</tr>
<tr>
<td>Band</td>
<td></td>
<td>The band containing the OLE Object control.</td>
</tr>
</tbody>
</table>
Properties for OLE Object control

<table>
<thead>
<tr>
<th>Property for OLE Object control</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BinaryIndex</td>
<td></td>
<td>An internal pointer.</td>
</tr>
<tr>
<td>Border</td>
<td>x</td>
<td>(exp) The type of border around the OLE Object control.</td>
</tr>
<tr>
<td>ClientName</td>
<td>x</td>
<td>The name of the OLE client in the server window.</td>
</tr>
<tr>
<td>ContentsAllowed</td>
<td>x</td>
<td>Whether the control can be embedded, linked, or both.</td>
</tr>
<tr>
<td>DisplayType</td>
<td>x</td>
<td>Whether the control displays an icon or contents.</td>
</tr>
<tr>
<td>GroupBy</td>
<td>x</td>
<td>(exp) The grouping columns for the transferred data.</td>
</tr>
<tr>
<td>Height</td>
<td>x</td>
<td>(exp) The height of the OLE Object control.</td>
</tr>
<tr>
<td>HideSnaked</td>
<td>x</td>
<td>Whether the control appears once per page when printing newspaper columns.</td>
</tr>
<tr>
<td>LinkUpdateOptions</td>
<td>x</td>
<td>How a linked control is updated.</td>
</tr>
<tr>
<td>Moveable</td>
<td>x</td>
<td>Whether the user can move the OLE Object control.</td>
</tr>
<tr>
<td>Name</td>
<td></td>
<td>The name of the OLE Object control.</td>
</tr>
<tr>
<td>Pointer</td>
<td>x</td>
<td>(exp) The pointer image when it is over the control.</td>
</tr>
<tr>
<td>Range</td>
<td>x</td>
<td>Method for choosing the rows transferred to the OLE control.</td>
</tr>
<tr>
<td>Resizeable</td>
<td>x</td>
<td>Whether the user can resize the OLE Object control.</td>
</tr>
<tr>
<td>SizeToDisplay</td>
<td>x</td>
<td>(exp) Whether the OLE Object control is automatically sized to the display area.</td>
</tr>
<tr>
<td>SlideLeft</td>
<td>x</td>
<td>(exp) Whether the control moves left to fill in space.</td>
</tr>
<tr>
<td>SlideUp</td>
<td>x</td>
<td>(exp) How the control moves up to fill in space.</td>
</tr>
<tr>
<td>Tag</td>
<td>x</td>
<td>(exp) The tag text for the control.</td>
</tr>
<tr>
<td>Target</td>
<td>x</td>
<td>(exp) The columns or expressions whose data you want to transfer to the OLE Object control.</td>
</tr>
<tr>
<td>Type</td>
<td></td>
<td>The control’s type, which is OLE.</td>
</tr>
<tr>
<td>Visible</td>
<td>x</td>
<td>(exp) Whether the control is visible.</td>
</tr>
<tr>
<td>Width</td>
<td>x</td>
<td>(exp) The width of the control.</td>
</tr>
<tr>
<td>X</td>
<td>x</td>
<td>(exp) The x coordinate of the control.</td>
</tr>
<tr>
<td>Y</td>
<td>x</td>
<td>(exp) The y coordinate of the control.</td>
</tr>
</tbody>
</table>

Properties for Oval, Rectangle, and RoundRectangle controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attributes</td>
<td></td>
<td>A list of the properties of the control.</td>
</tr>
<tr>
<td>Background.property</td>
<td>x</td>
<td>(exp) Background settings for the control.</td>
</tr>
<tr>
<td>Band</td>
<td></td>
<td>The band containing the control.</td>
</tr>
<tr>

<td>x</td>
<td>(exp) Settings for fill pattern and color.</td>
</tr>
</tbody>
</table>
## Additional properties for RoundRectangle controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

Properties for Oval, Rectangle, and RoundRectangle controls in DataWindow objects also apply to RoundRectangle controls.

<table>
<thead>
<tr>
<th>Property</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EllipseHeight</td>
<td>x</td>
<td>(exp) The radius of the vertical part of the rounded corner.</td>
</tr>
<tr>
<td>EllipseWidth</td>
<td>x</td>
<td>(exp) The radius of the horizontal part of the rounded corner.</td>
</tr>
</tbody>
</table>

## Properties for Picture controls in DataWindow objects

An x in the M (Modify) column means you can change the property. When (exp) is included in the description, you can specify a DataWindow expression as the value for that property.

<table>
<thead>
<tr>
<th>Property for a Picture</th>
<th>M</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccessibleDescription</td>
<td>x</td>
<td>A description of the control for use by assistive technology tools.</td>
</tr>
<tr>
<td>AccessibleName</td>
<td>x</td>
<td>A descriptive label for the control.</td>
</tr>
<tr>
<td>AccessibleRole</td>
<td>x</td>
<td>A description of the kind of user-interface element that the control is.</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
<td>A list of the properties of the picture.</td>
</tr>
</tbody>
</table>

<td>(exp) The y coordinate of the text control.</td>
</tr>
</tbody>
</table>

Title keyword

You use this property when generating DataWindow source code with the SyntaxFromSql method.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title(“string”)</td>
<td>The title for the DataWindow.</td>
</tr>
</tbody>
</table>
Alphabetical list of DataWindow object properties

The properties for DataWindow objects and controls within a DataWindow object follow in alphabetical order.

The simple Visual Basic example shown for most properties can be used in C# by adding a semicolon to the end of each statement.

To see the properties organized by type of control or syntax keyword, see “Controls in a DataWindow and their properties” on page 155.
**Accelerator**

**Description**
The accelerator key that a user can press to select a column in the DataWindow object.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.columnname.Accelerator
```

Describe and Modify argument:

```
"columnname.Accelerator { = 'acceleratorkey' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of the column for which you want to get or set the accelerator key.</td>
</tr>
<tr>
<td>acceleratorkey</td>
<td><em>(exp)</em> A string expression whose value is the letter that will be the accelerator key for columnname. Acceleratorkey can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**
An accelerator key for a column allows users to select a column (change focus) with a keystroke rather than with the mouse. The user changes focus by pressing the accelerator key in combination with the Alt key.

**In the painter** Select the control and set the value in the Properties view, Edit tab.

**Displaying the accelerator** The column does not display the key. To let users know what key to use, you can include an underlined letter in a text control that labels the column. When you enter the text control’s label, precede the character you want underlined with an ampersand (&).

**Accelerator keys and edit styles** To use an accelerator key with the CheckBox or RadioButton edit style, select the Edit edit style and specify the accelerator there.

**Examples**
```
dw1.Object.emp_name.Accelerator = 'A'
ls_data = dw1.Describe("emp_name.Accelerator")
dw1.Modify("emp_name.Accelerator='A'")
```
AccessibleDescription

Description
A description of the control and/or its purpose for use by accessibility tools such as readers for visually-impaired users.

Applies to
Column, computed field, picture, text, graph, group box, and button controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.AccessibleDescription

Describe and Modify argument:
"controlname.AccessibleDescription { = 'description ' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of the control for which you want to get or set the accessible description</td>
</tr>
<tr>
<td>description</td>
<td>(exp) A string that describes the control’s purpose or appearance</td>
</tr>
</tbody>
</table>

Usage
You do not need to supply a description if the AccessibleName and AccessibleRole properties adequately describe the control, as in the case of a button with the label OK. You should provide a description for a picture or report control.

In the painter
In the Other tab in the Properties view, type a description in the AccessibleDescription text box.

Examples

dw1.Object.b_1.AccessibleDescription = 'Scrolls to Next Row'
strData = dw1.Describe("b_1.AccessibleDescription")
dw1.Modify("b_1.AccessibleDescription='Scrolls to next row'")

AccessibleName

Description
A label that briefly describes the control for use by accessibility tools such as readers for visually-impaired users.

Applies to
Column, computed field, picture, text, graph, group box, and button controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.AccessibleName

Describe and Modify argument:
"controlname.AccessibleName { = 'description ' }"
**AccessibleName**

Usage

The AccessibleName property is a brief description, such as the text in a button or the name of a menu item.

**In the painter** In the Other tab in the Properties view, type a name in the AccessibleName text box.

**Examples**

```pascal
dw1.Object.b_1.AccessibleName = 'Next'
ls_data = dw1.Describe("b_1.AccessibleName")
dw1.Modify("b_1.AccessibleName='Next'")
```

**AccessibleRole**

**Description**

A description of the kind of user-interface element that the control is, for use by accessibility tools such as readers for visually-impaired users.

**Applies to**

Column, computed field, picture, text, graph, group box, and button controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.controlname.AccessibleRole
```

Describe and Modify argument:

```
"controlname.AccessibleRole { = 'enumeratedvalue ' }
```

**Parameter** | **Description**
---|---
`columnname` | The name of the control for which you want to get or set the accessible description

**Parameter** | **Description**
---|---
`description` | (exp) A number specifying the type of AccessibleRole as a numeric value of the AccessibleRole DataWindow constant.

**Usage**

The description is a member of the AccessibleRole enumerated variable. The default role is defaultrole! and is used when the role cannot be determined.
### Action

**Description**
The action a user can assign to a button control.

**Applies to**
Button controls

**Syntax**
PowerBuilder dot notation:

```
control.Name.Object.buttonname.Action
```

*Describe* and *Modify* argument:

```
"buttonname.Action = 'value'
```

**Table 3-1: AccessibleRole values for DataWindow controls**

<table>
<thead>
<tr>
<th>Control</th>
<th>AccessibleRole</th>
</tr>
</thead>
<tbody>
<tr>
<td>Button</td>
<td>pushbuttonrole!</td>
</tr>
<tr>
<td>Column</td>
<td>textrole!</td>
</tr>
<tr>
<td>Computed field</td>
<td>statictextrole!</td>
</tr>
<tr>
<td>Graph</td>
<td>diagramrole!</td>
</tr>
<tr>
<td>Group box</td>
<td>groupingrole!</td>
</tr>
<tr>
<td>Picture</td>
<td>graphicrole!</td>
</tr>
<tr>
<td>Text</td>
<td>statictextrole!</td>
</tr>
</tbody>
</table>

**In the painter**
In the Other tab in the Properties view, select a value in the AccessibleRole drop-down list.

**Examples**
```
ls_data = dw1.Object.b_1.AccessibleRole
ls_data = dw1.Describe("b_1.AccessibleRole")
```
## Chapter 3  
**DataWindow Object Properties**

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
<th>Description</th>
<th>Value returned to ButtonClicked event</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Retrieve</td>
<td>Retrieves rows from the database. The option to yield is not automatically turned on.</td>
<td>Number of rows retrieved.</td>
</tr>
<tr>
<td>3</td>
<td>Cancel</td>
<td>Cancels a retrieval that has been started with the option to yield.</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>PageNext</td>
<td>Scrolls to the next page.</td>
<td>The row displayed at the top of the DataWindow control when the scrolling is complete or attempts to go past the first row. -1 if an error occurs.</td>
</tr>
<tr>
<td>5</td>
<td>PagePrior</td>
<td>Scrolls to the prior page.</td>
<td>The row displayed at the top of the DataWindow control when the scrolling is complete or attempts to go past the first row. -1 if an error occurs.</td>
</tr>
<tr>
<td>6</td>
<td>PageFirst</td>
<td>Scrolls to the first page.</td>
<td>1 if successful. -1 if an error occurs.</td>
</tr>
<tr>
<td>7</td>
<td>PageLast</td>
<td>Scrolls to the last page.</td>
<td>The row displayed at the top of the DataWindow control when the scrolling is complete or attempts to go past the first row. -1 if an error occurs.</td>
</tr>
<tr>
<td>8</td>
<td>Sort</td>
<td>Displays Sort dialog box and sorts as specified.</td>
<td>1 if successful. -1 if an error occurs.</td>
</tr>
<tr>
<td>9</td>
<td>Filter</td>
<td>Displays Filter dialog box and filters as specified.</td>
<td>Number of rows filtered. Number &lt; 0 if an error occurs.</td>
</tr>
<tr>
<td>10</td>
<td>DeleteRow</td>
<td>If button is in detail band, deletes row associated with button; otherwise, deletes the current row.</td>
<td>1 if successful. -1 if an error occurs.</td>
</tr>
<tr>
<td>11</td>
<td>AppendRow</td>
<td>Inserts row at the end.</td>
<td>Row number of newly inserted row.</td>
</tr>
<tr>
<td>12</td>
<td>InsertRow</td>
<td>If button is in detail band, inserts row using row number associated with the button; otherwise, inserts row using the current row.</td>
<td>Row number of newly inserted row.</td>
</tr>
<tr>
<td>13</td>
<td>Update</td>
<td>Saves changes to the database. If the update is successful, a COMMIT is issued. If the update fails, a ROLLBACK is issued</td>
<td>1 if successful. -1 if an error occurs.</td>
</tr>
<tr>
<td>14</td>
<td>SaveRowsAs</td>
<td>Displays Save As dialog box and saves rows in the format specified.</td>
<td>Number of rows filtered.</td>
</tr>
<tr>
<td>15</td>
<td>Print</td>
<td>Prints one copy of the DataWindow object.</td>
<td>0</td>
</tr>
<tr>
<td>16</td>
<td>Preview</td>
<td>Toggles between preview and print preview.</td>
<td>0</td>
</tr>
</tbody>
</table>
Activation

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
<th>Description</th>
<th>Value returned to ButtonClicked event</th>
</tr>
</thead>
<tbody>
<tr>
<td>17</td>
<td>PreviewWithRulers</td>
<td>Toggles between rulers on and off.</td>
<td>0</td>
</tr>
<tr>
<td>18</td>
<td>QueryMode</td>
<td>Toggles between query mode on and off.</td>
<td>0</td>
</tr>
<tr>
<td>19</td>
<td>QuerySort</td>
<td>Specifies sorting criteria (forces query mode on).</td>
<td>0</td>
</tr>
<tr>
<td>20</td>
<td>QueryClear</td>
<td>Removes the WHERE clause from a query (if one was defined).</td>
<td>0</td>
</tr>
</tbody>
</table>

Usage

In the painter Select the control and set the value in the Properties view, General tab.

Examples

```
dw1.Object.b_retrieve.Action = "2"
setting = dw1.Describe("b_retrieve.Action")
dw1.Modify("b_retrieve.Action = '2'")
```

Activation

Description The way the server for the OLE object in the OLE Object control is activated. Choices include letting the user activate the object by double-clicking or putting activation under program control.

Applies to OLE Object controls

Syntax PowerBuilder dot notation:

```
dw_control.Object.olecontrolname.Activation
```

Describe and Modify argument:

```
"olecontrolname.Activation { = 'activationtype ' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>olecontrolname</td>
<td>The name of the OLE Object control for which you want to get or set the activation method.</td>
</tr>
<tr>
<td>activationtype</td>
<td>(exp) A number specifying the method of activation for the OLE object. Activationtype can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Values are:

- 0 – The object has to be activated with the Activate method.
- 1 – The user can activate the object by double-clicking on it.
- 2 – The object activates when the container gets focus.
CHAPTER 3  DataWindow Object Properties

Usage

**In the painter**  Select the control and set the value in the Properties view, Options tab.

Examples

```
dw1.Object.ole_report.Activation
ls_data = dw1.Describe("ole_report.Activation")
dw1.Modify("ole_report.Activation='2'")
```

**Alignment**

**Description**  The alignment of the control’s text within its borders.

**Applies to**  Column, Computed Field, and Text controls

**Syntax**  PowerBuilder dot notation:

```
dw_control.Object.controlname.Alignment
```

Describe and Modify argument:

```
"controlname.Alignment { = 'alignmentvalue' }"
```

SyntaxFromSql:

```
Text ( ... Alignment = alignmentvalue ... )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>controlname</code></td>
<td>The name of the control for which you want to get or set the alignment.</td>
</tr>
<tr>
<td><code>alignmentvalue</code></td>
<td>(exp) A number specifying the type of alignment for the text of controlname. Alignmentvalue can be a quoted DataWindow expression. Values are: 0 – (Default) Left 1 – Right 2 – Center 3 – Justified When generating DataWindow syntax with SyntaxFromSql, the setting for Alignment applies to all text controls used as column labels.</td>
</tr>
</tbody>
</table>

**Usage**  When you select justified, the last line of text is not stretched to fill the line. Controls with only one line of text look left aligned.

**In the painter**  Select the control and set the value using:

- Properties view, General tab
- StyleBar
Arguments

Examples

dw1.Object.emp_name_t.Alignment = 2
ls_data = dw1.Describe("emp_name.Alignment")
dw1.Modify("emp_name_t.Alignment='2'")

Arguments

Description
The retrieval arguments required by the data source. You specify retrieval arguments in the DataWindow’s SELECT statement and you provide values for the retrieval arguments when you call the Retrieve method.

Applies to
Database table for the DataWindow object

Not settable in PowerScript. Used in DataWindow syntax.

Syntax
Table(Arguments = ( (name1, type), (name2, type) ...) ... )

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the retrieval argument</td>
</tr>
<tr>
<td>type</td>
<td>The type of the argument:</td>
</tr>
<tr>
<td></td>
<td>• Date or a Date list</td>
</tr>
<tr>
<td></td>
<td>• DateTime or a DateTime list</td>
</tr>
<tr>
<td></td>
<td>• Number or a Number list</td>
</tr>
<tr>
<td></td>
<td>• String or a String list</td>
</tr>
<tr>
<td></td>
<td>• Time or a Time list</td>
</tr>
</tbody>
</table>

Usage

In the painter  Set the value in the SQL Select painter or Query painter.

Open the SQL Select painter by selecting Design>Data Source from the menu bar in the DataWindow painter, or create or open a query in the Query painter. Then select Design>Retrieval Arguments.

Attributes

Description
A tab-separated list of all the properties that apply to a control.

Applies to
DataWindow, Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Attributes
CHAPTER 3  DataWindow Object Properties

Describe argument:
"controlname.Attributes"

Examples
ls_data = dw1.Object.emp_name_t.Attributes
ls_data = dw1.Describe("DataWindow.Attributes")
ls_data = dw1.Describe("emp_name_t.Attributes")

Axis

Description
The list of items or the expression associated with an axis of a graph. Each item
is separated by a comma. You can ask for the list of categories on the Category
axis, the series on the Series axis, or the values on the Values axis.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:

dw_control.Object.graphname.axis

Describe and Modify argument:
"graphname.axis { = 'list' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The name of the graph within the DataWindow object for which you want to get or set the list of items for axis.</td>
</tr>
<tr>
<td>axis</td>
<td>An axis name. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Category</td>
</tr>
<tr>
<td></td>
<td>• Series</td>
</tr>
<tr>
<td></td>
<td>• Values</td>
</tr>
<tr>
<td>list</td>
<td>A string listing the categories, series, or values for the graph. The content of the list depends on the axis you specify. The items in the list are separated by commas. List is quoted.</td>
</tr>
</tbody>
</table>

Usage
In the painter  Select the graph control and set the value by selecting a column or expression for each axis in the Properties view, Data tab.

Examples
ls_data = dw1.Object.gr_1.Values
dw1.Object.gr_1.Series = "Actual, Budget"
ls_data = dw1.Describe("gr1.Category")
ls_data = dw1.Describe("gr1.Series")
ls_data = dw1.Describe("gr1.Values")
dw1.Modify("gr1.Series='Actual, Budget'")
**Axis.property**

**Description**
Settings that control the appearance of an axis on a graph.

**Applies to**
Graph controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.graphname.axis.property
```

Describe and Modify argument:
```
"graphname.axis.property = value"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>graphname</code></td>
<td>The name of the graph within the DataWindow object for which you want to get or set a property value for an axis.</td>
</tr>
<tr>
<td><code>axis</code></td>
<td>An axis name. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Category</td>
</tr>
<tr>
<td></td>
<td>• Series</td>
</tr>
<tr>
<td></td>
<td>• Values</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property for the axis. Properties and their settings are listed in the table that follows.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to be assigned to the property. For axis properties, <code>value</code> can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Property for Axis**

<table>
<thead>
<tr>
<th>Property for Axis</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoScale</td>
<td>(<code>exp</code>) A boolean number specifying whether PowerBuilder scales the axis automatically. Enabled when the axis displays nonstring data. Values are:</td>
</tr>
<tr>
<td></td>
<td>0 – No, do not automatically scale the axis.</td>
</tr>
<tr>
<td></td>
<td>1 – Yes, automatically scale the axis.</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Scale group.</td>
</tr>
<tr>
<td>DispAttr. <code>fontproperty</code> (<code>exp</code>)</td>
<td>Properties that control the appearance of the text that labels the axis divisions. For a list of font properties, see the main entry for DispAttr. <code>fontproperty</code>.</td>
</tr>
<tr>
<td></td>
<td>Painter: Text tab. Choose Category Axis Text, Series Axis Text, or Values Axis Text, and set font properties.</td>
</tr>
<tr>
<td>DisplayEvery NLabels (<code>exp</code>)</td>
<td>An integer specifying which major axis divisions to label. For example, 2 means label every other tick mark. Values 0 and 1 both mean label every tick mark. If the labels are too long, they are clipped.</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Major Divisions group (not available for all graph types).</td>
</tr>
</tbody>
</table>
## CHAPTER 3  DataWindow Object Properties

<table>
<thead>
<tr>
<th>Property for Axis</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DropLines (exp)</td>
<td>An integer indicating the type of drop line for the axis. Values are: 0 – None, 1 – Solid, 2 – Dash, 3 – Dot, 4 – DashDot, 5 – DashDotDot. Painter: Axis tab, Major Divisions group (not available for all graph types). Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>Frame</td>
<td>(exp) An integer indicating the type of line used for the frame. Values are 0–5. See DropLines in this table for their meaning. Available for 3D graph types. Painter: Axis tab, Line Style group. Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>Label</td>
<td>(exp) A string whose value is the axis label. Painter: Axis tab.</td>
</tr>
<tr>
<td>LabelDispAttr. <strong>fontproperty</strong></td>
<td>(exp) Properties that control the appearance of the axis label. For a list of font properties, see the main entry for DispAttr fontproperty. Painter: Text tab. Choose Category Axis Label, Series Axis Label, or Values Axis Label, and set font properties.</td>
</tr>
<tr>
<td>MajorDivisions</td>
<td>(exp) An integer specifying the number of major divisions on the axis. Painter: Axis tab, Major Divisions group.</td>
</tr>
<tr>
<td>MajorGridLine</td>
<td>(exp) An integer specifying the type of line for the major grid. Values are 0–5. See DropLines in this table for their meaning. Painter: Axis tab, Major Divisions group. Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>MajorTic</td>
<td>(exp) An integer specifying the type of the major tick marks. Values are: 1 – None, 2 – Inside, 3 – Outside, 4 – Straddle. Painter: Axis tab, Major Divisions group. Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>MaximumValue</td>
<td>(exp) A double specifying the maximum value for the axis. Painter: Axis tab, Scale group.</td>
</tr>
<tr>
<td>MinimumValue</td>
<td>(exp) A double specifying the minimum value for the axis. Painter: Axis tab, Scale group.</td>
</tr>
</tbody>
</table>
### Property for Axis

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MinorDivisions</td>
<td><em>(exp)</em> An integer specifying the number of minor divisions on the axis.</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Minor Divisions group.</td>
</tr>
<tr>
<td></td>
<td>Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>MinorGridLine</td>
<td><em>(exp)</em> An integer specifying the type of line for the minor grid.</td>
</tr>
<tr>
<td></td>
<td>Values are 0–5. See DropLines in this table for their meaning.</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Minor Divisions group.</td>
</tr>
<tr>
<td></td>
<td>Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>MinorTic</td>
<td><em>(exp)</em> An integer specifying the type of the minor tick marks.</td>
</tr>
<tr>
<td></td>
<td>Values are: 1 – None, 2 – Inside, 3 – Outside, 4 – Straddle</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Minor Divisions group.</td>
</tr>
<tr>
<td></td>
<td>Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>OriginLine</td>
<td><em>(exp)</em> An integer specifying the type of origin line for the axis.</td>
</tr>
<tr>
<td></td>
<td>Values are 0–5. See DropLines in this table for their meaning.</td>
</tr>
<tr>
<td></td>
<td>Enabled for numeric data axes.</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Line Style group.</td>
</tr>
<tr>
<td></td>
<td>Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>PrimaryLine</td>
<td><em>(exp)</em> An integer specifying the type of primary line for the axis.</td>
</tr>
<tr>
<td></td>
<td>Values are 0–5. See DropLines in this table for their meaning.</td>
</tr>
<tr>
<td></td>
<td>Painter: Axis tab, Line Style group.</td>
</tr>
<tr>
<td></td>
<td>Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>RoundTo</td>
<td><em>(exp)</em> A double specifying the value to which you want to round the axis values. Specify both a value and a unit (described next). Painter: Axis tab, Scale group.</td>
</tr>
<tr>
<td>RoundToUnit</td>
<td><em>(exp)</em> An integer specifying the units for the rounding value. The units must be appropriate for the axis datatype. Values are: 0 – Default, for an axis of any datatype 1 – Years, for an axis of type date or DateTime 2 – Months, for an axis of type date or DateTime 3 – Days, for an axis of type date or DateTime 4 – Hours, for an axis of type time or DateTime 5 – Minutes, for an axis of type time or DateTime 6 – Seconds, for an axis of type time or DateTime 7 – Microseconds, for an axis of type time or DateTime Painter: Axis tab, Scale group.</td>
</tr>
</tbody>
</table>
CHAPTER 3 DataWindow Object Properties

### Property for Axis

<table>
<thead>
<tr>
<th>Property for Axis</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScaleType</td>
<td><em>(exp)</em> An integer specifying the type of scale used for the axis. Values are: 1 – Scale_Linear 2 – Scale_Log10 3 – Scale_Loge Painter: Axis tab, Scale group.</td>
</tr>
<tr>
<td>ScaleValue</td>
<td><em>(exp)</em> An integer specifying the scale of values on the axis. Values are: 1 – Scale_Actual 2 – Scale_Cumulative 3 – Scale_Percentage 4 – Scale_CumPercent Painter: Axis tab, Scale group.</td>
</tr>
<tr>
<td>SecondaryLine</td>
<td><em>(exp)</em> An integer specifying the type of secondary line for the axis. The line is parallel to and opposite the primary line and is usually not displayed in 2D graphs. Values are 0–5. See DropLines in this table for their meaning. Painter: Axis tab, Line Style group. Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>ShadeBackEdge</td>
<td><em>(exp)</em> A boolean number specifying whether the back edge of the axis is shaded. Values are: 0 – No, the back edge is not shaded 1 – Yes, the back edge is shaded Painter: Axis tab. Enabled for 3D graphs only. Not supported by Render3D graph style.</td>
</tr>
<tr>
<td>Sort</td>
<td><em>(exp)</em> An integer specifying the way the axis values should be sorted. (Does not apply to the Values axis.) Values are: 0 – Unsorted 1 – Ascending 2 – Descending Painter: Axis tab, Line Style group.</td>
</tr>
</tbody>
</table>

### Usage

In the painter Select the graph control or the Graph DataWindow object and set the value in the Properties view. To set most axis properties, select the Axis tab and an axis in the Axis drop-down list. Font properties are set on the Text tab.

### Examples

```plaintext
string ls_data
ls_data = dw1.Object.gr_1.Category.AutoScale
```
BackColor

Description
The background color of a graph in a DataWindow.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:

dw_control.Object.graphname.BackColor

Describe and Modify argument:

"graphname.BackColor { = long }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The graph whose background color you want to get or set.</td>
</tr>
<tr>
<td>long</td>
<td>(exp) A long expression specifying the color (red, green, and blue values) to be used as the graph’s background color. Long can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage
In the painter
Select the graph control and set the value in the Properties view, General tab.

Examples

dw1.Object.graph_1.BackColor = 250
setting = dw1.Describe("graph_1.BackColor")
dw1.Modify("graph_1.BackColor=250")

Background.property

Description
Settings for the color and transparency of a control.

Applies to
Button, Column, Computed Field, GroupBox, Line, Oval, Rectangle, RoundRectangle, and Text controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Background.property

Describe and Modify argument:

"controlname.Background.property { = ' value ' }"
CHAPTER 3      DataWindow Object Properties

SyntaxFromSql:
  Column ( Background.property = value )
  Text ( Background.property = value )

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The control whose Background properties you want to get or set. When generating DataWindow syntax with SyntaxFromSql, the Background settings apply to all columns or all text controls.</td>
</tr>
<tr>
<td>property</td>
<td>A property that applies to the background of a control, as listed in the Property table below.</td>
</tr>
<tr>
<td>value</td>
<td>Values for the properties are shown below. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for Background</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brushmode</td>
<td>(exp) An integer indicating the type of “brush” to use for the gradient. Values are: 0 – Solid, 1 – Horizontal, 2 – Vertical, 3 – Angle, 4 – ScaledAngle, 5 – Radial.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group (not available in Web Forms DataWindow bands or in RichText, Graph, or OLE DataWindow objects).</td>
</tr>
<tr>
<td>Color</td>
<td>(exp) A long expression specifying the color (the red, green, and blue values) to be used as the control’s background color.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab</td>
</tr>
<tr>
<td>Transparency</td>
<td>(exp) An integer in the range 0 to 100, where 0 means that the column or control’s primary background is opaque and 100 that it is completely transparent.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab</td>
</tr>
<tr>
<td>Gradient.Angle</td>
<td>(exp) An integer indicating the angle in degrees (values are 0 to 360) used to offset the color and transparency gradient. This property is used only when the column’s or control’s background.gradient.mode takes values of 3 or 4.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Gradient.Color</td>
<td>(exp) A long specifying the color (the red, green, and blue values) to be used as the column or control’s secondary background color. The gradient defines transitions between the primary and secondary background colors.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group.</td>
</tr>
</tbody>
</table>
### Background.property

**Property for Background**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
</table>
| Gradient.Focus        | *(exp)* An integer in the range 0 to 100, specifying the distance (as a percentage) from the center where the background color is at its maximum. (For example, if the radial gradient is used and the value is set to 0, the color will be at the center of the background; if the value is set to 100, the color will be at the edges of the background.)  
Painter: Background tab, Gradient group |
| Gradient.Repetition.Mode | *(exp)* Specifies the mode for determining the number of gradient transitions for the column’s or control’s background color and transparency.  
Permitted values and their meanings are:  
• 0 Gradient.repetition.count determines the number of gradient transitions  
• 1 Gradient.repetition.length determines the number of gradient transitions  
Painter: Background tab, Gradient group. |
| Gradient.Repetition.Count | *(exp)* An integer specifying the number of gradient transitions for background color and transparency. A value of 0 indicates 1 transition. A value of 3 indicates 4 transitions. This property is used only when the gradient.repetition.mode property for the column or control takes the value of 0 (by count).  
Painter: Background tab, Gradient group. |
| Gradient.Repetition.Length | *(exp)* A long specifying the number of gradient transitions. This property is used only when the gradient.repetition.mode property for the column or control takes the value of 1 (by length). The units for the length that you assign for gradient transitions are set by the DataWindow object’s Units property.  
Painter: Background tab, Gradient group. |
| Gradient.Scale         | *(exp)* An integer in the range 0 to 100 specifying the rate of transition to the gradient color (as a percentage).  
Painter: Background tab, Gradient group |
| Gradient.Spread        | *(exp)* An integer in the range 0 to 100 indicating the contribution of the second color to the blend (as a percentage).  
Painter: Background tab, Gradient group |
| Gradient.Transparency  | *(exp)* An integer in the range 0 to 100, where 0 means that the column or control’s secondary (gradient) background is opaque and 100 that it is completely transparent. The gradient defines transitions between the primary and secondary transparency settings.  
Painter: Background tab, Gradient group. |

**Usage**

*In the painter*  
Select the control and set the value in the Properties view, Font tab for controls that have text and in the General tab for drawing controls (choose Transparent or a color).
When you choose a Brush Hatch fill pattern other than Solid for an Oval, Rectangle, or RoundRectangle control, the Background Color and the Brush Color are used for the pattern colors.

**Background color of a button**  The Background.Color property is not supported on Windows XP by default because the current XP theme controls the appearance of the button. Set the ShowBackColorOnXP property of the DataWindow object to force the color change to take effect.

**Background color of a line**  The background color of a line is the color that displays between the segments of the line when the pen style is not solid.

**Transparent background**  If Background.Mode is transparent (1), Background.Color is ignored.

**Background gradient properties**  Background gradient and transparency properties do not apply to DataWindow objects with the RichText, Graph, or OLE presentation style, and do not apply to the Line control. They are also not supported in .NET Web Forms targets.

**DropDownDataWindows and GetChild**  When you set Background.Color and Background.Mode for a column with a DropDownDataWindow, references to the DropDownDataWindow become invalid. Call GetChild again after changing these properties to obtain a valid reference.

**Examples**

```java
dw1.Object.oval_1.Background.Color = RGB(255, 0, 128)
ls_data = dw1.Describe("oval_1.Background.Color")
dw1.Modify("emp_name.Background.Color='11665407'")
ls_data = dw1.Describe("emp_name.Background.Mode")
dw1.Modify("emp_name.Background.Mode='1'")
dw1.Modify("rndrect_1.Background.Mode='0'")
SQLCA.SyntaxFromSQL(sql_syntax, &
    "Style(...) Column(Background.Mode=1 ...) ...", &
    ls_Errors)
SQLCA.SyntaxFromSQL(sql_syntax, &
    "Style(...) Column(Background.Color=11665407 ...)", &
    ls_Errors)
```
**BackImage**

**Description**
The column that contains the background image for an InkPicture control in a DataWindow.

**Applies to**
InkPicture controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.inkpicname.BackImage
```

**Describe and Modify argument:**
```
"inkpicname.BackImage( = colname )"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inkpicname</td>
<td>The graph whose background color you want to get or set.</td>
</tr>
<tr>
<td>colname</td>
<td>A string value specifying the name of the long binary column that contains the background image for the control.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**
Select the InkPicture control and set the value in the Properties view, Definition tab, Col for Image property. The image format can be JPEG, GIF, BMP, or ICO. If you change the image, call the `Retrieve` method to force the DataWindow to retrieve the new image.

**Examples**
```
sval = dw1.Object.inkpic_1.backimage

dw1.Object.inkpic_1.backimage = 'InkImg'
```

**Band**

**Description**
The band or layer in the DataWindow object that contains the control. The returned text is one of the following, where # is the level number of a group: detail, footer, header, header.#, summary, trailer.#, tree.level.#, foreground, background.

**Changing a control’s band**
Use the SetPosition method to change a control’s band at runtime.

**Applies to**
Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.controlname.Band
```
Describe and Modify argument:
"controlname.Band"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control within the DataWindow for which you want the band it occupies</td>
</tr>
</tbody>
</table>

Usage

**In the painter** Select the control and set the value in the Properties view, Position tab, Layer option. When the control’s layer is Band, you can drag the control into another band.

Examples

```powershell
ls_data = dw1.Object.emp_title.Band
ls_data = dw1.Describe("emp_title.Band")
```

**Bandname.property**

Description

Settings for the color, size, and pointer of a band in the DataWindow object. The gradient settings do not work in reports.

Applies to

DataWindows

Syntax

PowerBuilder dot notation:

```powershell
dw_control.Object.DataWindow.bandname.property
```

Describe and Modify argument:

"DataWindow.bandname(#).property ( = value )"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bandname</td>
<td>The identifier of a band in the DataWindow object. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Detail</td>
</tr>
<tr>
<td></td>
<td>• Footer</td>
</tr>
<tr>
<td></td>
<td>• Summary</td>
</tr>
<tr>
<td></td>
<td>• Header</td>
</tr>
<tr>
<td></td>
<td>• Trailer</td>
</tr>
<tr>
<td></td>
<td>• Tree.Level</td>
</tr>
</tbody>
</table>

**Setting the header.#, trailer.#, and tree.level.# bands**

You cannot use dot notation to set the header.#, trailer.#, and tree.level.# bands.
### Bandname.property

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>The number of the group or TreeView level you want when <code>bandname</code> is Header, Trailer, or Tree.Level. The group must exist.</td>
</tr>
<tr>
<td>property</td>
<td>A property that applies to the band, as listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>Values for the properties are shown in the following table.</td>
</tr>
</tbody>
</table>

#### Property for Bandname | Value

**Brushmode**  
*(exp)* An integer indicating the type of “brush” to use for the gradient.  
Values are:  
0 – Solid  
1 – Horizontal  
2 – Vertical  
3 – Angle  
4 – ScaledAngle  
5 – Radial  
Painter: Background tab, Gradient group (not available in Web Forms DataWindow bands or for RichText, Graph, or OLE DataWindow objects).

**Color**  
*(exp)* A long specifying the color (the red, green, and blue values) to be used as the band’s background color. *Value* can be a quoted DataWindow expression.  
Painter: General tab.

**Height**  
An integer specifying the height of the detail area in the unit of measure specified for the DataWindow.  
Painter: General tab.  
For another way of setting the height of the detail band, see the `SetDetailHeight` method.
### DataWindow Object Properties

**Property for Bandname** | **Value**  
---|---  
Height.AutoScale | Allows the band to grow to display a row, picture, or nested report without cutting off any of its content. In the detail band, selecting this property sets the minimum height for all rows to the size specified by the Height property for the band.  
Values are:  
No – Fixes the band height to the size set for the Height property of the band.  
Yes – Adjusts the band height to accommodate the full content of a row or the controls in the band. However, the band height cannot be reduced below the value set for the Height property of the band.  
This property can be especially useful to set on the detail band when it contains rows with a text column that you want to display without cutting off any of the text. The height of the detail band must not grow larger than a page, except when it contains nested DataWindows with the Report.Height.AutoScale property set to Yes.  
You can set this property on individual columns and controls as well as on the band itself. For more information, see the Height.AutoScale property for DataWindow objects.  
There are some limitations on the use of this property:  
- The Height.AutoScale property is not supported on DataWindows with Graph, Label, OLE, or Rich Text presentation styles.  
- Nested report overflow to the next page is supported in detail bands only.  
- Bands cannot be autosized if autosizing would preclude the display of at least one detail band row per page.  
Painter: General tab when the band is selected.  
  
Pointer | *(expr)* A string specifying a value of the Pointer enumerated datatype or the name of a cursor file (.CUR) to be used for the pointer. See the SetPointer method for a list of Pointer values. *Pointername* can be a quoted DataWindow expression. This property is not supported in Web DataWindows.  
Painter: Pointer tab.  
  
Suppress | A boolean that lets you suppress group headers after page breaks. You can set this property on group header bands only. When a group listing straddles a page break, all group headers for which you set this property will be suppressed. The suppressed headers do not display at the top of the page. However, if the page break coincides with the start of a new group, only headers above the current group header can be suppressed.  
Values are:  
No – Does not suppress group headers.  
Yes – Suppresses group headers.  
Painter: General tab when a group header band is selected.  
  
Transparency | *(expr)* An integer in the range 0 to 100, where 0 means that the background is opaque and 100 that it is completely transparent.  
Painter: Background tab.
<table>
<thead>
<tr>
<th>Property for Bandname</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gradient.Angle</td>
<td><em>(exp)</em> An integer indicating the angle in degrees (values are 0 to 360) used to offset the color and transparency gradient. This property is used only when the DataWindow band gradient.mode takes values of 3 or 4. Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Gradient.Color</td>
<td><em>(exp)</em> A long specifying the color (the red, green, and blue values) to be used as the band object’s secondary background color. The gradient defines transitions between the primary and secondary background colors. <em>Value</em> can be a quoted DataWindow expression. Painter: Background tab.</td>
</tr>
<tr>
<td>Gradient.Focus</td>
<td><em>(exp)</em> An integer in the range 0 to 100, specifying the distance (as a percentage) from the center where the background color is at its maximum. (For example, if the radial gradient is used and the value is set to 0, the color will be at the center of the background; if the value is set to 100, the color will be at the edges of the background.) Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Gradient.Scale</td>
<td><em>(exp)</em> An integer in the range 0 to 100 specifying the rate of transition to the gradient color (as a percentage). Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Gradient.Spread</td>
<td><em>(exp)</em> An integer in the range 0 to 100 indicating the contribution of the second color to the blend (as a percentage). Painter: Background tab, Gradient group.</td>
</tr>
</tbody>
</table>
| Gradient.Repetition.Mode| *(exp)* Specifies the mode for determining the number of gradient transitions for band background color and transparency. Permitted values and their meanings are:  
  - 0 Gradient.repetition.count determines the number of gradient transitions  
  - 1 Gradient.repetition.length determines the number of gradient transitions  
  Painter: Background tab, Gradient group. |
| Gradient.Repetition.Count| *(exp)* An integer specifying the number of gradient transitions for background color and transparency. A value of 0 indicates 1 transition. A value of 3 indicates 4 transitions. This property is used only when the gradient.repetition.mode property for the DataWindow band takes the value of 0 (by count). Painter: Background tab, Gradient group. |
| Gradient.Repetition.Length| *(exp)* A long specifying the number of gradient transitions. This property is used only when the gradient.repetition.mode property for the DataWindow band takes the value of 1 (by length). The units for the length that you assign for the band’s gradient transitions are set by the DataWindow object’s Units property. Painter: Background tab, Gradient group. |
### Property for Bandname

<table>
<thead>
<tr>
<th>Property for Bandname</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gradient.Transparency</td>
<td>( (exp) ) An integer in the range 0 to 100, where 0 means that the band’s secondary (gradient) background is opaque and 100 that it is completely transparent. The gradient defines transitions between the primary and secondary transparency settings. <strong>Painter</strong>: Background tab, Gradient group.</td>
</tr>
</tbody>
</table>

#### Usage

**In the painter**  Select the band by clicking the gray divider for the band. Set the value in the Properties view.

#### Examples

```powerbuilder
string ls_data
ls_data = dw1.Object.DataWindow.Detail.Height
dw1.Object.DataWindow.Detail.Pointer = "hand.cur"

ls_data = dw1.Describe("DataWindow.Detail.Height")
ls_data = &
    dw1.Describe("DataWindow.Detail.Height.AutoSize")
dw1.Modify("DataWindow.Detail.Pointer='hand.cur'")
dw1.Modify("DataWindow.Footer.Height=250")
ll_color = RGB(200, 200, 500)
dw1.Modify("DataWindow.Header.2.Color=" &
    + String(ll_color))
dw1.Modify("DataWindow.Trailer.2.Height=500")
dw1.Modify(" DataWindow.Summary.Pointer='c:\pb\total.cur' ")
```

---

### Bandname.Text

**Description**  (RichText presentation style only) The rich text content of the specified band as an ASCII string.

**Applies to**  DataWindows in the RichText presentation style

**Syntax**  PowerBuilder dot notation:

```powerbuilder
dw_control.Object.DataWindow.bandname.Text
```
Bands

Describe and Modify argument:

"DataWindow.bandname.Text { = rtfstring }

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bandname</td>
<td>The identifier of a band in the DataWindow object that has the RichText presentation style. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Detail</td>
</tr>
<tr>
<td></td>
<td>• Header</td>
</tr>
<tr>
<td></td>
<td>• Footer</td>
</tr>
<tr>
<td>rtfstring</td>
<td>A string whose value is the rich text content of the band. The string includes the rich text formatting codes, text, and input fields.</td>
</tr>
<tr>
<td></td>
<td>Text assigned to the header or footer band is ignored if RichText.HeaderFooter is set to no.</td>
</tr>
<tr>
<td></td>
<td>When you assign text using the Modify method or dot notation, nested quotes must be represented with tildes and quotes. If your data is a pure RTF string, use the PasteRTF method.</td>
</tr>
</tbody>
</table>

Usage

In the painter  Set the value by editing the content of each band in the painter workspace.

Examples

```powerbuilder
ls_data = dw1.Describe("DataWindow.Detail.Text")
```

Bands

Description

A list of the bands in the DataWindow object. The list can include one or more of the following band identifiers, where # is the level number of a group: Detail, Footer, Header, Header.#, Summary, Trailer.#, Tree.Level.#. The items in the list are separated by tabs.

Applies to

DataWindows

Syntax

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Bands
```

Describe argument:

"DataWindow.Bands"

Examples

```powerbuilder
ls_data = dw1.Object.DataWindow.Bands
ls_data = dw1.Describe("DataWindow.Bands")
```
### BinaryIndex

**Description**
An internal index that PowerBuilder uses to manage the OLE Object control in the library. There is no reason to get this value; the value has no external significance.

**Applies to**
OLE Object controls

**Syntax**
```
"olecontrolname.BinaryIndex"
```

### BitmapName

**Description**
Whether PowerBuilder interprets the column’s value as the name of a picture file and displays the picture instead of the text. BitmapName’s value is either Yes or No.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.columnname.BitmapName
```

Describe argument:
```
"columnname.BitmapName"
```

**Usage**
**In the painter** Select the control and set the value in the Properties view, General tab, Display As Pic option.

**Examples**
```
ls_data = dw1.Object.emp_name.BitmapName
ls_data = dw1.Describe("emp_name.BitmapName")
```

### Border

**Description**
The type of border for the control.

**Applies to**
Column, Computed Field, Graph, GroupBox, OLE, Picture, Report, TableBlob, and Text controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.controlname.Border
```

Describe and Modify argument:
```
"controlname.Border ( = 'value' )"
```
## Border

SyntaxFromSql:

```
Column ( ... Border = value ... )
Text ( ... Border = value ... )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control whose border you want to get or set. When generating DataWindow syntax with SyntaxFromSql, the Border setting applies to all columns or all text controls.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) A number specifying the type of border. Values are: 0 – None 1 – Shadow 2 – Rectangle 3 – Resize 4 – Line 5 – 3D Lowered 6 – 3D Raised The value can be a quoted DataWindow painter expression. When you change between Resize and another border, change the Resizeable property too so that the control’s appearance and behavior match. For columns, you can access the Border property with the GetBorderStyle and SetBorderStyle methods.</td>
</tr>
</tbody>
</table>

### Usage

**In the painter** Select the control and set the value in the Properties view, General tab.

Changing the Border setting between Resize and another border affects the Resizeable option on the Position tab. To make another border resizeable, choose the border then reset Resizeable.

On Windows XP, to display the border of a text column with the XP style (by default, a blue box), set the Border property to Lowered and the BackgroundColor of the font to Window Background.

For a Picture in a Web DataWindow that is a link, the default border displays unless you set the Border property to 0.

For examples of other ways to set properties, using Border as an example, see “What you can do with DataWindow object properties” on page 440.

### Examples

```powershell
string ls_data
ls_data = dw1.Object.emp_name_t.Border
dw1.Object.emp_name_t.Border='6'
```
Brush.property

Description
Settings for the fill pattern and color of a graphic control.

Applies to
Oval, Rectangle, and RoundRectangle controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Brush.property

Describe and Modify argument:
"controlname.Brush.property { = 'value'}"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the Line, Oval, Rectangle, RoundRectangle, or Text control whose Brush property you want to get or set.</td>
</tr>
<tr>
<td>property</td>
<td>A property that applies to the Brush characteristics of a control, as listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>Values for the properties are shown in the next table. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Property for Brush | Value |

Color

(exp) A long expression specifying the color (the red, green, and blue values) to be used to fill the control.

Hatch

(exp) A number expression specifying the fill pattern of controlname.

Values are:

0 – Horizontal
1 – Bdiagonal (lines from lower left to upper right)
2 – Vertical
3 – Cross
4 – Fdiagonal (lines from upper left to lower right)
5 – DiagCross
6 – Solid
7 – Transparent
8 - Background (use the settings on the Background tab)
**Brushmode**

**Usage**

**In the painter**  Select the control and set the value in the Properties view, General tab.

When you choose a Brush Hatch fill pattern other than Solid or Transparent, the Background Color and the Brush Color are used for the pattern colors.

**Examples**

```powerbuilder
string ls_data
ls_data = dw1.Describe("oval_1.Brush.Hatch")
dw1.Modify("oval_1.Brush.Color='16731766'")
```

**Brushmode**

Description  Setting that controls the type of “brush” used for the background or primary gradient.

Applies to  DataWindows

Syntax  PowerBuilder dot notation:

```
dw_control.brushmode
```

Describe and Modify argument:

```
"DataWindow (brushmode = { integer } )"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>The value to be assigned to the property:</td>
</tr>
<tr>
<td></td>
<td>0 – Solid</td>
</tr>
<tr>
<td></td>
<td>1 – HorizontalGradient</td>
</tr>
<tr>
<td></td>
<td>2 – VerticalGradient</td>
</tr>
<tr>
<td></td>
<td>3 – AngleGradient</td>
</tr>
<tr>
<td></td>
<td>4 – ScaledAngleGradient</td>
</tr>
<tr>
<td></td>
<td>5 – RadialGradient</td>
</tr>
<tr>
<td></td>
<td>6 – Picture</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  Set the brushmode value on the Background tab of the Properties view.

If you save to an EMF or WMF, the properties on the Background tab are not saved with the DataWindow.
The following table explains the possible values for Brushmode:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - Solid</td>
<td>The background is a solid color as selected</td>
</tr>
<tr>
<td>1 - HorizontalGradient</td>
<td>The color changes horizontally from the primary color (and transparency) to the secondary color (and transparency). The primary values are defined by the datawindow.color and datawindow.transparency, and the secondary values are defined by datawindow.gradient.color and datawindow.gradient.transparency. The gradient can be repeated using the datawindow.gradient.repetition.mode property.</td>
</tr>
<tr>
<td>2 - VerticalGradient</td>
<td>The color changes vertically from the background color (and transparency) to the secondary color (and transparency). The primary values are defined by the datawindow.color and datawindow.transparency, and the secondary values are defined by datawindow.gradient.color and datawindow.gradient.transparency. The gradient can be repeated using the datawindow.gradient.repetition.mode property.</td>
</tr>
<tr>
<td>3 - AngleGradient</td>
<td>The color changes at a specific angle off the horizontal from the background color (and transparency) to the secondary color (and transparency). The angle is specified in datawindow.gradient.angle. The primary values are defined by the datawindow.color and datawindow.transparency, and the secondary values are defined by datawindow.gradient.color and datawindow.gradient.transparency. The gradient can be repeated using the datawindow.gradient.repetition.mode property.</td>
</tr>
<tr>
<td>4 - ScaledAngleGradient</td>
<td>The color changes at an angle, which adjusts according to the changes in the aspect ratio of the DataWindow control. The starting angle is specified in datawindow.gradient.angle. The primary values are defined by the datawindow.color and datawindow.transparency, and the secondary values are defined by datawindow.gradient.color and datawindow.gradient.transparency. The gradient can be repeated using the datawindow.gradient.repetition.mode property.</td>
</tr>
</tbody>
</table>

**Category**

### 5 - RadialGradient

The background color (and transparency) starts at the center and slow changes to the gradient color (and transparency) at the boundaries of the DataWindow. The primary values are defined by `datawindow.color` and `datawindow.transparency`, and the secondary values are defined by `datawindow.gradient.color` and `datawindow.gradient.transparency`.

### 6 - Picture

A picture is used as the background. The image is specified in `datawindow.picture.file`.

**See also**

- Color
- Transparency (DataWindow objects)
- Gradient.property
- Picture.property

### CheckBox.property

**Description**

Settings for a column whose edit style is CheckBox.

**Applies to**

Column controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.columnname.CheckBox.property
```

**Describe and Modify argument:**

```
"columnname.CheckBox.property { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The column whose edit style is CheckBox for which you want to get or set property values.</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property for the CheckBox edit style, as listed in the table below.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>Values for the properties are shown in the table below. For CheckBox properties, <code>value</code> cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>
### CHAPTER 3  DataWindow Object Properties

<table>
<thead>
<tr>
<th>Property for CheckBox</th>
<th>Value</th>
</tr>
</thead>
</table>
| **LeftText**          | Whether the CheckBox label is to the left or right of the CheckBox.  
Values are:  
  Yes – Display the label on the left.  
  No – Display the label on the right.  
Painter: Edit tab, Left Text option. |
| **Off**               | A string constant specifying the column value when the CheckBox is off (unchecked). The resulting value must be the same datatype as the column.  
Painter: Edit tab, Data Value for Off option. |
| **On**                | A string constant specifying the value that will be put in the column when the CheckBox is on (checked). The resulting value must be the same datatype as the column.  
Painter: Edit tab, Data Value for On option. |
| **Other**             | A string constant specifying the value that will be put in the column when the CheckBox is in the third state (neither checked nor unchecked). The value must be the same datatype as the column.  
Painter: Edit tab, This option is available when ThreeStates is True. |
| **Scale**             | Whether you want to scale the 2D CheckBox. Takes effect only when the ThreeD property is No.  
Values are:  
  Yes – Scale the CheckBox.  
  No – Do not scale the CheckBox.  
Painter: Edit tab, Scale option. |
| **Text**              | A string specifying the CheckBox’s label text.  
Painter: Edit tab, Text option. |
| **ThreeD**            | Whether the CheckBox should be 3D.  
Values are:  
  Yes – Make the CheckBox 3D  
  No – Do not make the CheckBox 3D  
Painter: Edit tab, 3D Look option. |
| **ThreeStates**       | Whether the CheckBox should have three states.  
Values are:  
  Yes – The CheckBox has three states  
  No – The CheckBox does not have three states  
Painter: Edit tab, 3 States option. |

**Usage**  
**In the painter**  
Select the control and set values in the Properties view, Edit tab, when Style Type option is CheckBox.
ClientName

Description
The name of the OLE client. The default is “Untitled.” ClientName is used by
some applications in the server window’s title.

Applies to
OLE Object and TableBlob controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.ClientName

Describe and Modify argument:

"controlname.ClientName = '{ clientname }"

Parameter | Description
---|---
controlname | The name of a blob column or an OLE Object control.
clientname | (exp) A string expression to be used in the title of the server
application’s window. For a blob, the string usually includes
data from the current row so that the window title can identify
the blob’s row.

Begin the string with a tab (~t) when you modify the value so
that PowerBuilder evaluates the expression instead of
displaying it.

Usage
In the painter
Select the control and set the value in the Properties view,
Options tab.

Examples

cname = dw1.Object.emppict_blob.ClientName

dw1.Object.emppict_blob.ClientName = &
"-t'Data for ' String(emp_id)"

cname = dw1.Describe("emppict_blob.ClientName")

Examples

dw1.Modify("emp_gender.CheckBox.3D=no")
IF dw1.Describe("emp_status.CheckBox.LeftText") 
= "yes" THEN

dw1.Modify("emp_status2.CheckBox.LeftText=yes")
END IF

dw1.Modify("emp_status.CheckBox.Off='Terminated'")
dw1.Modify("emp_status.CheckBox.On='Active'")
dw1.Modify("emp_status.CheckBox.Other='Unknown'")

dw1.Object.emp_gender.CheckBox.ThreeD = "no"
IF dw1.Object.emp_status.CheckBox.LeftText = "yes" THEN

dw1.Object.emp_status2.CheckBox.LeftText = "yes"
END IF
dw1.Modify("emppict_blob.ClientName=" + & 
"-t="Data for -" + String(emp_id) ")

## Color

**Description**
The text color of the column or the background color of the DataWindow.

The color affected by the Color property depends on the control:

- For the DataWindow, Color specifies the background color
- For columns, computed fields, and text, Color specifies the text color
- For graphs, Color specifies the line color used for axes, borders around data markers, tick marks, and the outline of the box for 3D graphs

**Applies to**
DataWindow, Button, Column, Graph, and GroupBox controls

**Syntax**
PowerBuilder dot notation:

```
   dw_control.Object.DataWindow.Color
   dw_control.Object.controlname.Color
```

Describe and Modify argument:

```
   "DataWindow.Color { = long }
   "controlname.Color { = long }
```

**SyntaxFromSql:**

```
   DataWindow ( Color = long )
   Column ( Color = long )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>controlname</strong></td>
<td>The column whose text color you want to set or the graph whose line color you want to set.</td>
</tr>
<tr>
<td><strong>long</strong></td>
<td>(exp for columns only) A long value specifying the color of the column text or the DataWindow background. When you are specifying the text color of a column, you can specify a DataWindow expression in quotes. You cannot specify an expression for the DataWindow background color. When generating DataWindow syntax with SyntaxFromSql, the Color setting for Column applies to all columns.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter** For the DataWindow background, click the DataWindow to deselect all controls and set the value in the Properties view, Background tab, Color option. If you save to an EMF or WMF, the properties on the Background tab are not saved with the DataWindow.
For a column’s text color, select the column and set the value in the Properties view, Font tab, Text Color option.

For a graph’s line color, select the graph and set the value in the Properties view, General tab, Text Color option.

Examples

```powershell
string column_text_color
column_text_color = dw1.Object.emp_name.Color

dw1.Object.salary.Color = &
"0-tIf(salary>90000,255,65280)"

dw_back_color = dw1.Describe("DataWindow.Color")

column_text_color = dw1.Describe("emp_name.Color")

dw1.Modify( &
"salary.Color='0-tIf(salary>90000,255,65280)'")
```

See also

BackColor

Background.property

**ColType**

Description

The datatype of the column or computed field.

Applies to

Column and Computed Field controls

Syntax

PowerBuilder dot notation:

```
dw_control.Object.controlname.ColType
```

Describe argument:

```
"controlname.ColType"
```
In the painter The value of ColType is derived from the data or expression you specify for the control. The value is displayed in the Column Specifications view.

Date column types
If you define a DataWindow with a column of type Date and deploy it with a DBMS that uses the DateTime datatype, set the StaticBind database parameter to 0 or No. This forces PowerBuilder to get a result set description before retrieving data and adjust the bind information if necessary.

For more information, see the StaticBind DBParm parameter in the online Help.

Examples

```powerbuilder
string ls_coltype
ls_coltype = dw1.Object.emp_id.ColType
ls_coltype = dw1.Describe("emp_id.ColType")
```
\textbf{Column.Count}

**Description**

The number of columns in the DataWindow object.

**Applies to**

DataWindows

**Syntax**

PowerBuilder dot notation:

\[ \text{dw\_control.Object.DataWindow.Column.Count} \]

Describe argument:

"DataWindow.Column.Count"

**Usage**

**In the painter** The value is determined by the number of columns you select in the SQL Select painter, whether or not they are displayed.

**Column limit**

There is a limit of 1000 on the number of columns in a DataWindow object.

**Examples**

```
string ls_colcount
ls_colcount = dw1.Describe("DataWindow.Column.Count")
```

\textbf{ContentsAllowed}

**Description**

The way the OLE Object control holds the OLE object. You can restrict the container to only embedded or only linked objects, or you can allow either type.

**Applies to**

OLE Object controls

**Syntax**

PowerBuilder dot notation:

\[ \text{dw\_control.Object.olecontrolname.ContentsAllowed} \]

Describe and Modify argument:

"\text{olecontrolname.ContentsAllowed ( = 'contentstype' )}"
CHAPTER 3      DataWindow Object Properties

DataWindow Reference

211

Usage

In the painter  Select the control and set the value in the Properties view, Options tab, Contents option.

Examples

```pascal
string ls_data
ls_data = dw1.Object.ole_report.ContentsAllowed

dw1.Object.ole_report.ContentsAllowed = 2
ls_data = dw1.Describe("ole_report.ContentsAllowed")

dw1.Modify("ole_report.ContentsAllowed='2'")
```

Criteria

Description  The search condition of the WHERE clause for a related report. The Criteria property defines the connection between the related report and the DataWindow.

Applies to  Report controls

Syntax  PowerBuilder dot notation:

```pascal
dw_control.Object.reportname.Criteria
```

Describe and Modify argument:

```pascal
"reportname.Criteria { = string }
```

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>olecontrolname</td>
<td>The name of the OLE Object control for which you want to get or set the type of contents.</td>
</tr>
<tr>
<td>contentstype</td>
<td>A number specifying whether the OLE object in the control has to be embedded, has to be linked, or can be either embedded or linked. Values are: 0 – Embedded 1 – Linked 2 – Any</td>
</tr>
</tbody>
</table>

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reportname</td>
<td>The name of the report control for which you want to get or set Criteria.</td>
</tr>
<tr>
<td>string</td>
<td>An expression that will be the search condition of the WHERE clause for the related report.</td>
</tr>
</tbody>
</table>
Criteria.property

Examples

\[
\begin{align*}
\text{ls\_colcount} &= \text{dw1}\text{.Object}\text{.rpt}\_1\text{.Criteria} \\
\text{dw1}\text{.Object}\text{.rpt}\_1\text{.Criteria} &= "\text{emp\_id=:emp\_id}" \\
\text{ls\_colcount} &= \text{dw1}\text{.Describe("rpt}\_1\text{.Criteria")} \\
\text{dw1}\text{.Modify("rpt}\_1\text{.Criteria='emp}\_id=:emp\_id'"})
\end{align*}
\]

See also

Nest_Arguments DataWindow object property

Criteria.property

Description

Settings for the Prompt for Criteria dialog box. When Prompt for Criteria is enabled, PowerBuilder prompts the user to specify criteria for retrieving data whenever the Retrieve method is called. Note that the Required property also affects query mode.

Syntax

PowerBuilder dot notation:

\[
\text{dw\_control}\text{.Object}\text{.columnname}\text{.Criteria.property}
\]

Describe and Modify argument:

\[
"\text{columnname}\text{.Criteria.property \{ = value \}}"
\]

Parameter | Description
--- | ---
\text{columnname} | The name of the column for which you want to get or set Prompt for Criteria properties.
\text{property} | A property for the Prompt for Criteria dialog box. Properties and their settings are listed in the table below.
\text{value} | A Yes or No value to be assigned to the property. For Criteria properties, \text{value} cannot be a DataWindow expression.

Property for Criteria | Value
--- | ---
Dialog | Whether Prompt for Criteria is on for \text{columnname}.

Values are:

- Yes – Include \text{columnname} in the Prompt for Criteria dialog box.
- No – (Default) Do not include \text{columnname} in the Prompt for Criteria dialog box.

If the Dialog property is Yes for at least one column in the DataWindow, then PowerBuilder displays the Prompt for Criteria dialog box when the Retrieve method is called.

Painter: Column Specifications view, Prompt check box.
CHAPTER 3      DataWindow Object Properties

**DataWindow Object Properties**

<table>
<thead>
<tr>
<th>Property for Criteria</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Override&gt;Edit</td>
<td>Whether the user must enter data in the Prompt for Criteria dialog box according to the edit style defined for the column in the DataWindow object or be allowed to enter any specifications in a standard edit control.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Allow the user to override the column’s edit style and enter data in a standard edit control.</td>
</tr>
<tr>
<td></td>
<td>No – (Default) Constrain the user to the edit style for the column.</td>
</tr>
<tr>
<td></td>
<td>Painter: Properties view, General tab, Override Edit option.</td>
</tr>
<tr>
<td>Required</td>
<td>Whether the user is restricted to the equality operator (=) when specifying criteria in query mode and in the Prompt for Criteria dialog box.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Require the user to use the equality operator only.</td>
</tr>
<tr>
<td></td>
<td>No – (Default) Allow the user to use any relational operator, including =, &lt;&gt;, &lt;, &gt;, &gt;=, and &lt;=.</td>
</tr>
<tr>
<td></td>
<td>Painter: Properties view, General tab, Equality Required option.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  Set the values using the menus and Properties view as described in the table above.

**Examples**

```java
string setting
setting = dw1.Object.empname.Criteria.Dialog

dw1.Object.empname.Criteria.Dialog= "Yes"
setting = dw1.Describe("empname.Criteria.Dialog")
dw1.Modify("empname.Criteria.Dialog=Yes")
dw1.Modify("empname.Criteria.Override_Edit=Yes")
dw1.Modify("empname.Criteria.Required=No")

IF dw1.Describe("empname.Edit.Style") = "dddw" THEN
dw1.Modify("empname.Criteria.Override_Edit=Yes")
END IF
```

**Crosstab.property**

**Description**  Settings for a DataWindow object whose presentation style is Crosstab.

**Applies to**  DataWindows

**Syntax**  PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Crosstab.property
```

DataWindow Reference  213
Crosstab.property

Describe and Modify argument:

"DataWindow.Crosstab.property ( = value )"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for a Crosstab DataWindow. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>A string expression listing the items to be assigned to the property. For Crosstab properties, value is always quoted and can be a DataWindow expression.</td>
</tr>
</tbody>
</table>

**Property for Crosstab**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns</td>
<td>$(exp)$ A string containing a comma- or tab-separated list of the names of columns that make up the columns of the crosstab. These are the columns that display across the top of the crosstab. Painter: Columns option.</td>
</tr>
<tr>
<td>Rows</td>
<td>$(exp)$ A string containing a comma- or tab-separated list of the names of columns that make up the rows of the crosstab. Painter: Rows option.</td>
</tr>
<tr>
<td>SourceNames</td>
<td>$(exp)$ A string containing a comma-separated list of column names to be displayed in the Crosstab Definition dialog box. The default names are the column names from the database. Painter: Source Data option.</td>
</tr>
<tr>
<td>StaticMode</td>
<td>A string indicating whether a dynamic crosstab should be put into a static mode. The dynamic crosstab remains in static mode until you set StaticMode to No. While the dynamic crosstab is in static mode, you can manipulate the properties of individual columns. Values are: Yes – StaticMode is enabled No – (Default) StaticMode is disabled Painter: Not set in painter.</td>
</tr>
<tr>
<td>Values</td>
<td>$(exp)$ A string containing a comma- or tab-separated list of expressions that will be used to calculate the values of the crosstab. Painter: Values option.</td>
</tr>
</tbody>
</table>

**Usage**

In the painter For DataWindow objects with the Crosstab presentation style, set the values in the Crosstab Definition dialog box. To display the dialog box, right-click in the Design view to display the pop-up menu and select Crosstab.

**Examples**

```

setting = dw1.Describe("DataWindow.Crosstab.Columns")
dw1.Modify("DataWindow.Crosstab.Columns='dept_id'")
```
dw1.Modify("DataWindow.Crosstab.Rows='salary'")
dw1.Modify("DataWindow.Crosstab.SourceNames=" & + "'Order Number, Item Number, Price'")
dw1.Modify("DataWindow.Crosstab.Values='empname'")
dw1.Modify("DataWindow.Crosstab.StaticMode='yes'")

See also CrosstabDialog function in the PowerScript Reference

**CSSGen.property**

**Description**
Settings that specify the physical path to which a generated CSS style sheet is published and the URL where the style sheet is located.

**Applies to**
DataWindow objects

**Syntax**
PowerBuilder dot notation:

dw_control.Object.DataWindow.CSSGen.property

**Describe and Modify argument:**

"DataWindow.CSSGen.property { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• PublishPath</td>
</tr>
<tr>
<td></td>
<td>• ResourceBase</td>
</tr>
<tr>
<td></td>
<td>• SessionSpecific</td>
</tr>
<tr>
<td>value</td>
<td>(exp) PublishPath – a string that specifies the physical path of the Web site folder to which PowerBuilder publishes the generated CSS style sheet</td>
</tr>
<tr>
<td></td>
<td>(exp) ResourceBase – a string that specifies the URL of the generated CSS style sheet to be referenced in a link element in the XHTML page</td>
</tr>
<tr>
<td></td>
<td>(exp) SessionSpecific – a boolean that when set to “yes” forces a session-specific ID to be applied to any generated document names that would otherwise be shared</td>
</tr>
</tbody>
</table>

**Usage**
The PublishPath folder must correspond to the URL specified in the ResourceBase property. At runtime, after PowerBuilder generates the CSS style sheet to the PublishPath folder, it includes it in the final XHTML page by referencing it with the ResourceBase property in a <link> element.
Typically you share style (CSS), layout (XSLT), and control definitions (JS) for use by all clients; however, if you use dynamic DataWindow objects customized for specific clients, you can force generation of the DataWindow presentation-related document names to be specific to each client. You do this by setting the CSSGen.SessionSpecific property to "yes". This eliminates the possibility of server-side contention for presentation formats when the DataWindow generation is specific to the client.

**In the painter** In the Web Generation tab in the Properties view for the DataWindow object, select CSS from the Format to Configure list, specify the Resource Base and Publish Path locations, and check the Session-specific CSS, XSLT and JS file names check box if you want to force generation of client-specific names.

### Examples

These statements set the CSSGen.ResourceBase and CSSGen.PublishPath properties:

```powershell
'http://www.myserver.com/xmlsource'
dw1.Object.DataWindow.CSSGen.PublishPath= &
'C:\work\outputfiles\xmlsource'
```

This statement sets the CSSGen.SessionSpecific property for a JSP page:

```powershell
dwGen.Modify
("DataWindow.CSSGen.SessionSpecific='Yes'");
```

### Data

**Description**
A tab-separated list describing the data in the DataWindow object.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```powershell
dw_control.Object.DataWindow.Data
```

**Describe argument:**

"DataWindow.Data"

**Examples**

```powershell
string setting
setting = dw1.Object.DataWindow.Data
setting = dw1.Describe("DataWindow.Data")
```
**Data.HTML**

**Description**
A string containing HTML and JavaScript that represents data and presentation of the DataWindow object.

The data is presented in a read-only HTML table or data-entry form, depending on settings of other properties.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Data.HTML
```

Describe argument:

```
"DataWindow.Data.HTML"
```

**Usage**
When HTMLDW is set to False, the value of Data.HTML is the same as the value of HTMLTable—a read-only HTML table that displays all retrieved rows.

When the HTMLDW property is set to True, the value of Data.HTML is a form that supports data input with client scripts for data validation and events. The generated string for Data.HTML includes:

- HTML input elements
- JavaScript for validating newly entered data based on validation rules in the DataWindow object
- HTML and JavaScript for navigation based on DataWindow Button controls with scrolling actions
- State information about the modification status of data items

JavaScript for navigation passes the state of the DataWindow back to the page server in two variables: `objectname_action` and `objectname_context`. It also passes back any page parameters defined in the HTMLGen.SelfLinkArgs property. All the HTMLGen.property values affect the way HTML is generated.

The resulting Web DataWindow is a client-side control for a Web page with events and methods that can cooperate with a server component for a Web-based data entry application. For more information about the Web DataWindow, see the *DataWindow Programmers Guide*.

**Exceptions**
If the DataWindow is in print preview mode, or there are no columns with non-zero tab order, the setting of HTMLDW is ignored and the generated HTML is a read-only table, not a data-entry form.
To generate a simple form without data entry methodality, you can use the GenerateHTMLForm method.

**Examples**

```powerbuilder
strHtml = dw1.Object.DataWindow.Data.HTML
strHtml = dw1.Describe("DataWindow.Data.HTML")
```

## Data.HTMLTable

**Description**
The data in the DataWindow object described in HTML table format. This property is used in the process of dynamically creating Web pages from a database.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.DataWindow.Data.HtmlTable
```
Describe argument:
```
"DataWindow.Data.HtmlTable"
```

**Usage**
Some presentation styles translate better into HTML than others. The Tabular, Group, Freeform, Crosstab, and Grid presentation styles produce good results. The Composite, RichText, OLE 2.0, TreeView, and Graph presentation styles produce HTML tables based on the result set only and not on the presentation style. DataWindows with overlapping controls in them might not produce the desired results. Nested reports are ignored; they are not included in the generated HTML.

The generated HTML for Data.HTMLTable is a read-only HTML Table element that includes:

- All retrieved rows (in contrast to the Web DataWindow, which paginates the result set)
- Hyperlinks for text, pictures, computed fields, and columns as defined in the HTML.property settings

Data.HTMLTable is not affected by the HTMLDW property and does not generate a client control with events and support for scripting in the Web page.

The values of HTMLGen.Browser and HTMLGen.Version affect the generated HTML. Setting these properties causes the generated HTML to be optimized for a specific level of HTML support or specific browser using style sheets and absolute positioning, if possible. For more information, see HTMLGen.property.
The resulting HTML table does not allow data entry. To produce HTML forms, see the Data.HTML property and the GenerateHTMLForm method.

**An easy way to see a DataWindow in a Web browser** The HTML string that the Data.HTMLTable property returns is equivalent to the string that is saved when you use either the File>Save Rows As HTML Table option in the DataWindow painter workspace or the SaveAs method.

To see what a DataWindow will look like, save it as an HTML file and open the file in a Web browser such as Netscape.

**In the painter** When HTMLDW is not selected, the Design>HTML Preview displays the value of Data.HTMLTable. Save an HTML file that you can use later in a browser with File>Save Rows As; set the Save As Type to HTML Table.

**Examples**

```powerbuilder
ls_html = dw1.Object.DataWindow.Data.HTMLTable
ls_html = dw1.Describe("DataWindow.Data.HTMLTable")
```

---

**Data.XHTML**

**Description**

A string containing the row data content of the DataWindow object in XHTML format.

**Applies to**

DataWindows

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Data.XHTML
```

Describe argument:

```
"DataWindow.Data.XHTML"
```

**Usage**

If any of the Export.XHTML properties have been set, the string that is generated reflects the values of these properties.

The resulting XHTML string contains a `<form>` element that supports data input, which works with separate client scripts for data validation and events. This JavaScript is either dynamically generated and/or statically deployed. To generate static JavaScript, select HTML/XHTML from the Format to Configure drop-down list on the JavaScript Generation page in the DataWindow painter Properties view, specify names for the files you want to generate, and click the Generate File button. For more information about JavaScript caching, see the *DataWindow Programmers Guide*. 
The generated XHTML string also includes:

- XHTML input elements
- XHTML and JavaScript for navigation based on DataWindow button controls with scrolling actions
- State information about the modification status of data items

JavaScript for navigation passes the state of the DataWindow back to the page server in two variables: objectname_action and objectname_context. It also passes back any page parameters defined in the HTMLGen.SelfLinkArgs property. All applicable HTMLGen.property values also affect the way the XHTML is generated.

The resulting XML Web DataWindow is a client-side control for a Web page, such as a JSP page, with events and methods that can cooperate with a server component for a Web-based data entry application.

Examples

The following statements set the template used by the DataWindow dw1 to t_report and return the generated XHTML document to the string ls_XHTML. To generate the string, the final statement invokes the XML Web DataWindow generator to generate the XHTML, CSS, and JavaScript components, applying the t_report template to the generated XHTML and CSS style sheet.

```powerbuilder
string strXHTML
dw1.Modify("DataWindow.Export.XHTML.UseTemplate = 't_report'")
strXHTML = dw1.Describe("DataWindow.Data.XHTML")
```

---

**Data.XML**

**Description**
A string containing the row data content of the DataWindow object in XML format.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Data.XML
```

**Describe argument**

"DataWindow.Data.XML"
Usage

If any of the Export.XML properties have been set, the string that is generated reflects the values of these properties.

**Note** If Export.XML.SaveMetaData is set to MetaDataExternal, no metadata is generated in the string.

Examples

The following statements set the template used by the DataWindow `dw1` to `t_report`, specify that metadata in the XMLSchema format should be included in the generated XML, and return the generated XML document to the string `ls_xml`.

```powerbuilder
string ls_xml
dw1.Modify("DataWindow.Export.XML.UseTemplate = 't_report'")
dw1.Modify("DataWindow.Export.XML.SaveMetaData = MetaDataInternal!")
dw1.Modify("DataWindow.Export.XML.MetaDataType = XMLSchema!")
ls_xml = dw1.Object.DataWindow.Data.XML
```

**Data.XMLDTD**

Description

A string containing the full document type definition (DTD) of the XML output for a DataWindow object.

Applies to

DataWindows

Syntax

PowerBuilder dot notation:

```powerbuilder
dw_control.Object.DataWindow.Data.XMLDTD
```

Describe argument:

"DataWindow.Data.XMLDTD"

Usage

Use this property to return the full DTD of the XML output of a DataWindow object separately from the generated XML document itself. The export template used affects the generated DTD.

Examples

The following statements set the template used by the DataWindow `dw1` to `t_report` and return the generated DTD to the string `ls_xml_dtd`.

```powerbuilder
string ls_xml_dtd
dw1.Object.DataWindow.Export.XML.UseTemplate = 't_report'
ls_xml_dtd = dw1.Object.DataWindow.Data.XMLDTD
```
### Data.XMLSchema

**Description**
A string containing the full schema of the XML output of a DataWindow object.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:
```
    dw_control.Object.DataWindow.Data.XMLSchema
```

Describe argument:
```
    "DataWindow.Data.XMLSchema"
```

**Usage**
Use this property to return the full schema of the XML output of a DataWindow object separately from the generated XML document itself. The export template used affects the generated schema.

**Examples**
The following statements set the template used by the DataWindow `dw1` to `t_report` and return the XML schema to the string `ls_xml_schema`.
```powerbuilder
    string ls_xml_schema
    dw1.Object.DataWindow.Export.XML.UseTemplate = 't_report'
```

### Data.XMLWeb

**Description**
A string containing browser-specific JavaScript that performs the XSLT transformation on the browser after the XML Web DataWindow generator generates all necessary components.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:
```
    dw_control.Object.DataWindow.Data.XMLWeb
```

Describe argument:
```
    "DataWindow.Data.XMLWeb"
```

**Usage**
If any of the Export.XHTML properties have been set, the string that is generated reflects the values of these properties.

The resulting XHTML string contains a `<form>` element that supports data input, which works with separate client scripts for data validation and events.
This JavaScript is either dynamically generated and/or statically deployed. To generate static JavaScript, select HTML/XHTML from the Format to Configure drop-down list on the JavaScript Generation page in the DataWindow painter Properties view, specify names for the files you want to generate, and click the Generate File button. For more information about JavaScript caching, see the DataWindow Programmers Guide.

The generated XHTML string also includes:

- XHTML input elements
- XHTML and JavaScript for navigation based on DataWindow button controls with scrolling actions
- State information about the modification status of data items

JavaScript for navigation passes the state of the DataWindow back to the page server in two variables: objectname_action and objectname_context. It also passes back any page parameters defined in the HTMLGen.SelfLinkArgs property. All applicable HTMLGen.property values also affect the way the XHTML is generated.

The resulting XML Web DataWindow is a client-side control for a Web page, such as a JSP page, with events and methods that can cooperate with a server component for a Web-based data entry application.

**Examples**

The following statements set the template used by the DataWindow dw1 to t_report and return the generated XSLT transformation to the string ls_transform. To generate the string, the final statement invokes the XML Web DataWindow generator to generate the XML, XSLT, CSS, and JavaScript components, applying the t_report template to the generated XSLT and CSS style sheet.

```java
string ls_transform
dw1.Modify("DataWindow.Export.XHTML.UseTemplate = 't_report'")
ls_transform = dw1.Object.DataWindow.Data.XMLWeb
```

**Data.XSLFO**

**Description**

A string containing XSL Formatting Objects (XSL-FO) that represents the data and presentation of the DataWindow object.

**Applies to**

DataWindows
### DataObject

**Syntax**

PowerBuilder dot notation:

\[ \text{dw\_control.Object.DataWindow.Data.XSLFO} \]

Describe argument:

\"DataWindow.Data.XSLFO\"

**Usage**

Use this property to return the data and presentation of a DataWindow object in XSL-FO format. The export template associated with the DataWindow object does not affect the generated string.

**Examples**

The following statements return the data and presentation of the DataWindow object \( \text{dw1} \) to the string \( \text{ls\_xslfo} \) in XSL-FO format.

```powershell
string ls_xslfo
ls_xslfo = dw1.Object.DataWindow.Data.XSLFO
```

---

### DataObject

**Description**

The name of the DataWindow object that is the nested report within the main DataWindow object.

**Applies to**

Report controls

**Syntax**

PowerBuilder dot notation:

\[ \text{dw\_control.Object.reportname.DataObject} \]

Describe and Modify argument:

\"reportname.DataObject = 'dwname' \"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reportname</td>
<td>The name of the Report control in the main DataWindow object for which you want to get or set the nested DataWindow object</td>
</tr>
<tr>
<td>dwname</td>
<td>A string naming a DataWindow object in the application’s libraries that is the DataWindow object for the report within the main DataWindow object</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**

Select the control and set the value in the Properties view, General tab, Report option.

**Examples**

```powershell
setting = dw1.Object.rpt_1.DataObject
dw1.Object.rpt_1.DataObject = "d\_empdata"

setting = dw1.Describe("rpt_1.DataObject")
dw1.Modify("rpt_1.DataObject='d\_empdata'")
```
**dbAlias**

**Description**
The name of the database column but with the table alias in place of the table name, if any. This value can be used to construct the update DataWindow syntax dynamically when an alias name is used for a table.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.columnname.dbAlias
```

Describe and Modify argument:
```
"columnname.dbAlias { = 'dbcolumnname' }
```

**Parameter** | **Description**
--- | ---
`columnname` | The name of the column for which you want the name of the corresponding database column qualified with the table alias name
`dbcolumnname` | The name of the database column associated with `columnname` qualified with the alias of the table name

**Usage**
DbAlias is the name of the database column in the format `tablealiasname.columnname`. The value of dbAlias does not include the quotes that can be part of the SQL syntax. This property can be used to construct update DataWindow syntax dynamically when an alias is used for a column name.

**In the painter** You can specify an alias for a table in the SQL Select painter if you convert the SQL statement for a DataWindow object to syntax. Select Design>Data Source to open the SQL Select painter, then select Design>Convert to Syntax. In the text window that displays, add the alias name to the FROM clause using the syntax:
```
FROM tablename tablealiasname
```

**Examples**
Suppose a DataWindow object has the following SQL Select syntax, with the alias “emp” for the table “employee”:
```
SELECT "emp"."emp_id",
     "emp"."emp_fname",
     "emp"."emp_lname"
     "emp"."dept_id"
     "emp"."salary"
FROM "employee" "emp"
WHERE ( "emp"."salary" > 50000 )
```
Then the following statements would return the string “employee.emp_id” in
ls_name and the string “emp.emp_id” in ls_alias:

```powerbuilder
string strAlias, strName
strName = dw1.Object.emp_id.dbName
strAlias = dw1.Object.emp_id.dbAlias
strName = dw1.Describe("emp_id.dbName")
strName = dw1.Describe("emp_id.dbAlias")
```

See also

### dbAlias

**Description**
The name of the database column. PowerBuilder uses this value to construct
the update syntax.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.columnname.dbName
```

Describe and Modify argument:
```
"columnname.dbName { = 'dbcolumnname' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of the column for which you want the name of the corresponding database column</td>
</tr>
<tr>
<td>dbcolumnname</td>
<td>The name of the database column associated with columnname</td>
</tr>
</tbody>
</table>

**Usage**
DbName is the name of the database column in the format
tablename.columnname. The value of dbName does not include the quotes that
can be part of the SQL syntax.

**In the painter**
The Syntax view in the SQL Select painter displays the
database column names (they can be shown with quotes).

**Examples**
```
dbcol = dw1.Object.emp_id.dbName
dw1.Object.emp_id.dbName = "emp_id"
```
```
dbcol = dw1.Describe("emp_id.dbName")
dw1.Modify("emp_id.dbName='emp_id'")
```

See also

dbAlias
**dddw.property**

**Description**
Properties that control the appearance and behavior of a column with the DropDownDataWindow edit style.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.columnname.dddw.property
```

Describe and Modify argument:

```
"columnname.dddw.property ( = value )"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of a column that has the DropDownDataWindow edit style.</td>
</tr>
<tr>
<td>property</td>
<td>A property for the DropDownDataWindow column. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. For dddw properties, value cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for dddw</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AllowEdit</strong></td>
<td>Whether the user can type a value as well as choose from the DropDownDataWindow’s list.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Typing is allowed.</td>
</tr>
<tr>
<td></td>
<td>No – (Default) Typing is not allowed.</td>
</tr>
<tr>
<td></td>
<td>Call GetChild after setting dddw.AllowEdit to get a valid reference to the column’s DropDownDataWindow.</td>
</tr>
<tr>
<td></td>
<td>Painter: Allow Editing option.</td>
</tr>
<tr>
<td><strong>AutoHScroll</strong></td>
<td>Whether the DropDownDataWindow automatically scrolls horizontally when the user enters or deletes data.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – (Default) Scroll horizontally automatically.</td>
</tr>
<tr>
<td></td>
<td>No – Do not scroll automatically.</td>
</tr>
<tr>
<td></td>
<td>Painter: Auto Horizontal Scroll option.</td>
</tr>
<tr>
<td><strong>AutoRetrieve</strong></td>
<td>Whether the DropDownDataWindow data is retrieved when the parent DataWindow data is retrieved.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – (Default) Data is automatically retrieved.</td>
</tr>
<tr>
<td></td>
<td>No – Data must be retrieved separately.</td>
</tr>
<tr>
<td></td>
<td>Painter: AutoRetrieve option.</td>
</tr>
</tbody>
</table>
### Property for dddw

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Case</strong></td>
<td>The case of the text in the DropDownDataWindow.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>

</tr>
<tr>
<td></td>
<td>Yes – Display a horizontal scroll bar.</td>
</tr>
<tr>
<td></td>
<td>No – Do not display a horizontal scroll bar.</td>
</tr>
<tr>
<td></td>
<td>Painter: Horizontal Scroll Bar option.</td>
</tr>
<tr>
<td><strong>HSplitScroll</strong></td>
<td>Whether the horizontal scroll bar is split. The user can adjust the split position.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Split the horizontal scroll bar so the user can scroll the display and data columns separately.</td>
</tr>
<tr>
<td></td>
<td>No – The horizontal scroll bar is not split.</td>
</tr>
<tr>
<td></td>
<td>Painter: Split Horizontal Scroll Bar option.</td>
</tr>
<tr>
<td><strong>Limit</strong></td>
<td>An integer from 0 to 32767 specifying the maximum number of characters that can be entered in the DropDownDataWindow. Zero means unlimited.</td>
</tr>
<tr>
<td></td>
<td>Painter: Limit option.</td>
</tr>
<tr>
<td><strong>Lines</strong></td>
<td>An integer from 0 to 32767 specifying the number of lines (values) to display in the DropDownDataWindow. This property does not apply in Web pages because the browser controls how the DropDownDataWindow displays.</td>
</tr>
<tr>
<td></td>
<td>Painter: Lines in DropDown option.</td>
</tr>
</tbody>
</table>
### Property for dddw | Value
--- | ---
Name | A string whose value is the name of the DropDownDataWindow associated with the column. Call `GetChild` after setting `dddw.Name` to get a valid reference to the column’s DropDownDataWindow. Painter: DataWindow option.
NilIsNull | Whether to set the data value of the DropDownDataWindow to null when the user leaves the edit box blank. Values are:
- Yes – Make the Empty string null.
- No – Do not make the empty string null. Painter: Empty String is null option.
PercentWidth | An integer specifying the width of the drop-down portion of the DropDownDataWindow as a percentage of the column’s width. For example, 300 sets the display width to three times the column width. Call `GetChild` after setting `dddw.PercentWidth` to get a valid reference to the column’s DropDownDataWindow. Painter: Width of DropDown option.
Required | Whether the column is required. Values are:
- Yes – Required.
- No – (Default) Not required. Painter: Required option.
ShowList | Whether the ListBox portion of the DropDownDataWindow displays when the column has focus. A down arrow does not display at the right end of the DropDownDataWindow when `dddw.ShowList` is yes. Values are:
- Yes – Display the list whenever the column has the focus.
- No – Do not display the list until the user selects the column. Painter: Always Show List option.
UseAsBorder | Whether a down arrow displays at the right end of the DropDownDataWindow. Values are:
- Yes – Display the arrow.
- No – Do not display the arrow. Note that if `ShowList` is set to Yes, the column ignores the UseAsBorder property and the arrow never displays. Painter: Always Show Arrow option.
### Usage

**DropDownDataWindows and GetChild**  When you set some of the dddw properties, as noted in the table, references to the DropDownDataWindow become invalid. Call GetChild again after changing these properties to obtain a valid reference.

To retrieve a DropDownDataWindow when the AutoRetrieve property is set to “false”, you can access the object data as follows:

```plaintext
DataWindowChild mgr_id
dw1.GetChild ("dept_head_id", mgr_id)
mgr_id.SetTransObject (SQLCA)
mgr_id.Retrieve ( )
```

You can also pass a retrieval argument for the retrieve on the child DataWindow object.

**Doing a reset to clear the data**  When a DropDownDataWindow is retrieved, its data is kept with its own Data Object. If you retrieve the DropDownDataWindow and then set the AutoRetrieve property on the parent to “false”, the data for the child is not cleared on a reset and re-retrieve of the parent.

To clear data from a DropDownDataWindow, you must call Reset on the child DataWindow object:

```plaintext
dw1.GetChild ("dept_head_id", mgr_id)
mgr_id.reset ( )
```

### Examples

```plaintext
ls_data = dw1.Describe("emp_status.dddw.AllowEdit")
dw1.Modify("emp_status.dddw.Case='Any'")
dw1.Modify("emp_status.dddw.DataColumn='status_id'")
dw1.Modify("emp_status.dddw.Limit=30")
dw1.Modify("emp_status.dddw.Name='d_status'")
dw1.Modify("emp_status.dddw.PercentWidth=120")
dw1.Object.emp_status.dddw.Case = "Any"
```

### Property for dddw

<table>
<thead>
<tr>
<th>Property for dddw</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VScrollBar</td>
<td>Whether a vertical scroll bar displays in the DropDownDataWindow for long lists. Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Display a vertical scroll bar.</td>
</tr>
<tr>
<td></td>
<td>No – Do not display a vertical scroll bar.</td>
</tr>
<tr>
<td></td>
<td>Painter: Vertical Scroll Bar option.</td>
</tr>
</tbody>
</table>

**In the painter**  Select the control and set values in the Properties view, Edit tab, when Style Type is DropDownDW.
```powershell
string ls_data
ls_data = dw1.Object.emp_status.ddw.AllowEdit"
```

**ddlb.property**

**Description**
Properties that control the appearance and behavior of a column with the DropDownListBox edit style.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.columnname.ddlb.property
```

**Describe and Modify argument:**

```
"columnname.ddlb.property { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of a column that has the DropDownListBox edit style.</td>
</tr>
<tr>
<td>property</td>
<td>A property for the DropDownListBox column. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. For dddw properties, value cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>

<td>Sorted option.</td>
</tr>
</tbody>
</table>
CHAPTER 3  DataWindow Object Properties

Usage
In the painter  Select the control and set the value in the Properties view, Edit tab, when Style Type is DropDownListBox.

Examples
ls_data = dw1.Describe("emp_status.ddlb.AllowEdit")
dw1.Modify("emp_status.ddlb.Case='Any'")
dw1.Modify("emp_status.ddlb.Limit=30")

string ls_data
ls_data = dw1.Object.emp_status.ddlb.AllowEdit
dw1.Object.emp_status.ddlb.Case = "Any"

DefaultPicture
Description  Specifies whether a button displays a default picture for the button’s action.
Applies to  Button controls
Syntax  PowerBuilder dot notation:

dw_control.Object.buttonname.DefaultPicture

Describe and Modify argument:
"buttonname.DefaultPicture { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buttonname</td>
<td>The name of the button to which you want to assign an action.</td>
</tr>
</tbody>
</table>
### Usage

Default pictures can be associated with all button action types. However, the only default pictures provided for use on a Web DataWindow are: InsertRow, PageFirst, PageLast, PageNext, PagePrior, Retrieve, and Update. These pictures are included as GIF files in the `DWACTION115.JAR` file in the `Sybase\Shared\PowerBuilder` directory.

For the Web DataWindow, you must uncompress the `dwaction115.jar` file, deploy the individual GIF files to your Web site, and specify their location with the DataWindow HTMLGen.ResourceBase property that you can set on the JavaScript Generation page in the DataWindow’s Property view.

You can add your own action pictures by setting the DefaultPicture property to False and setting the Filename property to the file name for the picture you want. You can use a URL instead of a complete path to qualify the file name, and you can leave off the URL server name, mapping prefix, and folder name if you set them in the HTMLGen.ResourceBase property.

A user-defined action does not have a default picture associated with it.

#### In the painter

Select the control and set the value in the Properties view, General tab, Action Default Picture option. When the DefaultPicture is not set, you can specify a picture file name in the Picture File property. Button pictures can be BMP, GIF, or JPEG files.

#### Examples

```powershell
dw1.Object.b_name.DefaultPicture = "Yes"

setting = dw1.Describe("b_name.DefaultPicture")
dw1.Modify("b_name.DefaultPicture = 'No'")
```

#### See also

- HTMLGen.property
- DefaultPicture
- Filename
**Depth**

**Description**
The depth of a 3D graph.

**Applies to**
Graph controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.graphname.Depth
```

Describe and Modify argument:
```
"graphname.Depth { = 'depthpercent' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The graph control within the DataWindow for which you want to set the depth.</td>
</tr>
<tr>
<td>depthpercent</td>
<td><em>(exp)</em> An integer whose value is the depth of the graph, specified as a percentage of the graph’s width. <em>Depthpercent</em> can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**
**In the painter** Select the control and set the value in the Properties view, General tab, Depth slider.

**Examples**
```
string setting
setting = dw1.Object.graph_1.Depth
dw1.Object.graph_1.Depth = 70

setting = dw1.Describe("graph_1.Depth")
dw1.Modify("graph_1.Depth='70'")
```

---

**Detail_Bottom_Margin**

**Description**
The size of the bottom margin of the DataWindow’s detail area.

**Applies to**
Style keywords

**Syntax**
SyntaxFromSql:
```
Style ( Detail_Bottom_Margin = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the size of the bottom margin of the detail area in the units specified for the DataWindow.</td>
</tr>
</tbody>
</table>

**Examples**
```
SQLCA.SyntaxFromSQL(sqlstring, 
    'Style(...Detail_Bottom_Margin = 25 ...)', 
    & errstring)
```
**Detail_Top_Margin**

**Description**
The size of the top margin of the DataWindow's detail area.

**Applies to**
Style keywords

**Syntax**
SyntaxFromSql:
```
Style ( Detail_Top_Margin = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the size of the top margin of the detail area in the units specified for the DataWindow.</td>
</tr>
</tbody>
</table>

**Examples**
```
SQLCA.SyntaxFromSQL(sqlstring, & 'Style(...Detail_Top_Margin = 25 ...)', & errstring)
```

**Detail.property**

See Bandname.property.

**DispAttr.fontproperty**

**Description**
Settings for the appearance of various text components of a graph.

**Applies to**
Properties of Graph controls, as noted throughout this discussion

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.graphname.property.DispAttr.fontproperty
```

Describe and Modify argument:
```
"graphname.property.DispAttr.fontproperty { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The Graph control in a DataWindow for which you want to get or set font appearance values.</td>
</tr>
</tbody>
</table>
A text component of the graph, such as an Axis keyword (Category, Series, or Values), Legend, Pie, or Title, specifying the graph component whose appearance you want to get or set. These properties have their own entries. These values are listed in the following table.

You can also set font properties for the label of an axis with the following syntax:

```
"graphname.axis.LabelDispAttr.fontproperty = value"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property that controls the appearance of text in the graph. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>fontproperty</td>
<td>The value to be assigned to fontproperty. Value can be a quoted DataWindow expression.</td>
</tr>
<tr>
<td>value</td>
<td>Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for DispAttr</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment</td>
<td>(exp) The alignment of the text. Values are: 0 – Left, 1 – Right, 2 – Center. Painter: Alignment option. Alignment for axis labels and text not supported by Render3D graph style.</td>
</tr>
<tr>
<td>AutoSize</td>
<td>(exp) Whether the text element should be autosized according to the amount of text being displayed. Values are: 0 – Do not autosize, 1 – Autosize. Painter: Autosize check box.</td>
</tr>
<tr>
<td>BackColor</td>
<td>(exp) A long value specifying the background color of the text. Painter: BackColor option.</td>
</tr>
<tr>
<td>DisplayExpression</td>
<td>An expression whose value is the label for the graph component. The default expression is the property containing the text for the graph component. The expression can include the text property and add other variable text. Painter: Display Expression option.</td>
</tr>
</tbody>
</table>
### DispAttr.fontproperty

<table>
<thead>
<tr>
<th>Property for DispAttr</th>
<th>Value</th>
</tr>
</thead>
</table>
| Font.CharSet          | *(exp)* An integer specifying the character set to be used. Values are: | 0 – ANSI  
|                       | 1 – The default character set for the specified font  
|                       | 2 – Symbol  
|                       | 128 – Shift JIS  
|                       | 255 – OEM  
|                       | Painter: FontCharSet option. |
| Font.Escapement       | *(exp)* An integer specifying the rotation for the baseline of the text in tenths of a degree. For example, a value of 450 rotates the text 45 degrees. 0 is horizontal. Painter: Escapement option. |
| Font.Face             | *(exp)* A string specifying the name of the font face, such as Arial or Courier. Painter: FaceName option. |
| Font.Family           | *(exp)* An integer specifying the font family (Windows uses both face and family to determine which font to use). Values are: | 0 – AnyFont  
|                       | 1 – Roman  
|                       | 2 – Swiss  
|                       | 3 – Modern  
|                       | 4 – Script  
|                       | 5 – Decorative  
|                       | Painter: Family option. |
| Font.Height           | *(exp)* An integer specifying the height of the text in the unit of measure for the DataWindow. To specify size in points, specify a negative number. Not available when AutoSize is checked. Painter: Size option, specified in points. |
| Font.Italic           | *(exp)* Whether the text should be italic. Values are: | 0 – Not italic (default)  
|                       | 1 – Italic  
|                       | Painter: Italic option. |
| Font.Orientation      | Same as Escapement. |
| Font.Pitch            | *(exp)* The pitch of the font. Values are: | 0 – The default pitch for your system  
|                       | 1 – Fixed  
|                       | 2 – Variable  
|                       | Painter: Pitch option. |
### CHAPTER 3  DataWindow Object Properties

#### Property for DispAttr | Value
---|---
**Font.Strikethrough** | \( (exp) \) Whether the text should be crossed out.  
Values are:  
0 – Not crossed out (default)  
1 – Crossed out  
Painter: Strikeout option.

**Font.Underline** | \( (exp) \) Whether the text should be underlined.  
Values are:  
0 – Not underlined (default)  
1 – Underlined  
Painter: Underline option.

**Font.Weight** | \( (exp) \) An integer specifying the weight of the text, for example, 400 for normal or 700 for bold.  
Painter: Set indirectly using the Bold option.

**Font.Width** | \( (exp) \) An integer specifying the width of the font in the unit of measure specified for the DataWindow. Width is usually unspecified, which results in a default width based on the other properties.  
Painter: Width option.

**Format** | \( (exp) \) A string containing the display format for the text.  
Painter: Format option.

**TextColor** | \( (exp) \) A long specifying the color to be used for the text.  
Painter: TextColor option.

#### Usage

**In the painter**  Select the control and set values in the Properties view, Text tab. Settings apply to the selected item in the Text Object list box.

#### Examples

```plaintext
setting = &
   dw1.Describe("Category.LabelDispAttr.Font.Face")

    'Arial'")
dw1.Modify("gr_1.Title.DispAttr.DisplayExpression=" &
    '"Title + -"-n-" + Today()'")
```
**DisplayType**

**Description**

The way the OLE Object control displays the OLE object it contains. It can display an icon or an image of the object’s contents. The image is reduced to fit inside the OLE container.

Both the icon and the image are provided by the OLE server. If the OLE server does not support a contents view, PowerBuilder displays an icon even if DisplayType is set to contents.

**Applies to**

OLE Object controls

**Syntax**

PowerBuilder dot notation:

```
   dw_control.Object.olecontrolname.DisplayType
```

Describe and Modify argument:

```
   "olecontrolname.DisplayType { = 'type'}"
```

**Parameter** | **Description**
--- | ---
```
   olecontrolname
```

The name of the OLE Object control for which you want to get or set the type of display.

```
   type
```

A number specifying whether the user will see an icon or an image of the OLE object’s contents. *Type* can be a quoted DataWindow expression.

Values are:

- 0 – Icon
- 1 – Content

**Usage**

**In the painter**

Select the control and set the value in the Properties view, Options tab.

**Examples**

```
   string ls_data
   ls_data = dw1.Object.ole_report.DisplayType
   dw1.Object.ole_report.DisplayType = 1

   ls_data = dw1.Describe("ole_report.DisplayType")
   dw1.Modify("ole_report.DisplayType='1'")
```
CHAPTER 3  DataWindow Object Properties

**Edit.property**

**Description**
Settings that affect the appearance and behavior of columns whose edit style is Edit.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:

```
da_w_control.Object.columnname.Edit.property
```

Describe and Modify argument:

```
"columnname.Edit.property { = value }"
```

**SyntaxFromSql:**

```
Column ( Edit.property = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The column with the Edit edit style for which you want to get or set property values. You can specify the column name or a pound sign (#) and the column number.</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property for the column’s Edit style. Properties and their settings are listed in the table below. The table identifies the properties you can use with SyntaxFromSql.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to be assigned to the property. For most Edit properties, you cannot specify a DataWindow expression. The exception is Edit.Format.</td>
</tr>
</tbody>
</table>

**Property for Edit**

<table>
<thead>
<tr>
<th>Value</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AutoHScroll</strong></td>
<td>Whether the edit control scrolls horizontally automatically when data is entered or deleted.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Scroll horizontally automatically.</td>
</tr>
<tr>
<td></td>
<td>No – Do not scroll horizontally automatically.</td>
</tr>
<tr>
<td></td>
<td>You can use AutoHScroll with SyntaxFromSql. The setting applies to all the columns in the generated syntax.</td>
</tr>
<tr>
<td></td>
<td>Painter: Auto Horizontal Scroll option.</td>
</tr>
</tbody>
</table>
**Edit.property**

<table>
<thead>
<tr>
<th>Property for Edit</th>

<tr>
<td></td>
<td>You can use AutoVScroll with SyntaxFromSql. The setting applies to all the columns in the generated syntax.</td>
</tr>
<tr>
<td></td>
<td>Painter: Auto Vertical Scroll option.</td>
</tr>
<tr>
<td><strong>Case</strong></td>
<td>The case of the text in the edit control.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Any – Character of any case allowed.</td>
</tr>
<tr>
<td></td>
<td>Upper – Characters converted to uppercase.</td>
</tr>
<tr>
<td></td>
<td>Lower – Characters converted to lowercase.</td>
</tr>
<tr>
<td></td>
<td>Painter: Case option.</td>
</tr>
<tr>
<td><strong>CodeTable</strong></td>
<td>Whether the column has a code table.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Code table defined.</td>
</tr>
<tr>
<td></td>
<td>No – No code table defined.</td>
</tr>
<tr>
<td></td>
<td>Painter: Use Code Table option.</td>
</tr>
<tr>
<td><strong>DisplayOnly</strong></td>
<td>Whether the column is display only.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Do not allow the user to enter data; make the column display only.</td>
</tr>
<tr>
<td></td>
<td>No – (Default) Allow the user to enter data.</td>
</tr>
<tr>
<td></td>
<td>Painter: Display Only option.</td>
</tr>
<tr>
<td></td>
<td>For conditional control over column editing, use the Protect property.</td>
</tr>
</tbody>
</table>
### Property for Edit

<table>
<thead>
<tr>
<th>Property for Edit</th>
<th>Value</th>
</tr>
</thead>
</table>
| AutoSelect       | Whether to select the contents of the edit control automatically when it receives focus.  
Values are:  
Yes – Select automatically.  
No – Do not select automatically.  
You can use AutoSelect with SyntaxFromSql. The setting applies to all the columns in the generated syntax.  
Painter: Auto Selection option. |
| AutoVScroll      | Whether the edit box scrolls vertically automatically when data is entered or deleted.  
Values are:  
Yes – Scroll vertically automatically.  
No – Do not scroll vertically automatically.  
You can use AutoVScroll with SyntaxFromSql. The setting applies to all the columns in the generated syntax.  
Painter: Auto Vertical Scroll option. |
| Case             | The case of the text in the edit control.  
Values are:  
Any – Character of any case allowed.  
Upper – Characters converted to uppercase.  
Lower – Characters converted to lowercase.  
Painter: Case option. |
| CodeTable        | Whether the column has a code table.  
Values are:  
Yes – Code table defined.  
No – No code table defined.  
Painter: Use Code Table option. |
| DisplayOnly      | Whether the column is display only.  
Values are:  
Yes – Do not allow the user to enter data; make the column display only.  
No – (Default) Allow the user to enter data.  
Painter: Display Only option.  
For conditional control over column editing, use the Protect property. |
### Edit.property

<table>
<thead>
<tr>
<th>Property for Edit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FocusRectangle</td>
<td>Whether a dotted rectangle (the focus rectangle) surrounds the current row of the column when the column has focus. Values are: Yes – Display the focus rectangle. No – Do not display the focus rectangle. You can use FocusRectangle with SyntaxFromSql. The setting applies to all the columns in the generated syntax. Painter: Show Focus Rectangle option.</td>
</tr>
<tr>
<td>Format</td>
<td>(exp) A string containing the display format of the edit control. The value for Format is quoted and can be a DataWindow expression. Painter: Format option (do not use quotes around the value).</td>
</tr>
<tr>
<td>HScrollBar</td>
<td>Whether a horizontal scroll bar displays in the edit control. Values are: Yes – Display the horizontal scroll bar. No – Do not display the horizontal scroll bar. Painter: Horizontal Scroll Bar option.</td>
</tr>
<tr>
<td>Limit</td>
<td>A number specifying the maximum number of characters (0 to 32,767) that the user can enter. 0 means unlimited. Painter: Limit option.</td>
</tr>
<tr>
<td>Name</td>
<td>A string whose value is the name of the predefined edit style associated with the column. Named styles are defined in the Database painter and can be reused. Specifying a name that has not been previously defined associates the name with the column but does not define a new edit style. Painter: Style Name option.</td>
</tr>
<tr>
<td>NilIsNull</td>
<td>Whether to set the value of the edit control to null when the user leaves it blank. Values are: Yes – Make the empty string null. No – Do not make the empty string null. Painter: Empty String is Null option.</td>
</tr>
<tr>
<td>Password</td>
<td>Whether to assign secure display mode to the column. When the user enters characters, they display as asterisks (*). Values are: Yes – Assign secure display mode to the column. No – Do not assign secure-display mode to the column. If you change the Password property, you should also change the Format property to display the results you want (for example, ****). Painter: Password option.</td>
</tr>
</tbody>
</table>
### Property for Edit

<table>
<thead>
<tr>
<th>Property for Edit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>Whether the column is required. Values are: Yes – It is required. No – It is not required. Painter: Required option.</td>
</tr>
<tr>
<td>Style</td>
<td>(Describe only) Returns the edit style of the column. Painter: Style Type option.</td>
</tr>
<tr>
<td>UseEllipsis</td>
<td>Whether an ellipsis (three dots) displays when a column with the Edit edit style contains character data that is too long for the display column in the DataWindow. The ellipsis does not display when the column has focus. Values are: Yes – Truncate the data and add an ellipsis. No – Truncate the data. Do not add an ellipsis. The property is ignored if you: Check Autosize Height on the Position page or set the Height.Autosize property in a script. Specify an expression for the Escapement property on the Font page or set the Font.Escapement property in a script to rotate the text. The UseEllipsis DataWindow object property is not supported in Web Forms applications. Painter: Use Ellipsis check box on the Format page.</td>
</tr>
<tr>
<td>ValidateCode</td>
<td>Whether the code table will be used to validate user-entered values. Values are: Yes – Use the code table. No – Do not use the code table. Painter: Validate option, available when Use Code Table is selected.</td>
</tr>
</tbody>
</table>

### Usage

**In the painter** Select the control and set values in the Properties view, Edit tab, when Style Type is Edit.

### Examples

```java
string setting
setting = dw1.Object.emp_name>Edit.AutoHScroll
dw1.Object.emp_name>Edit.Required = "no"
setting = dw1.Describe("emp_name>Edit.AutoHScroll")
```
EditMask.property

```powerbuilder
dw1.Modify("emp_name.Edit.Required=no")
dw1.Object.col1.Edit.UseEllipsis = Yes
dw1.Modify("col1.Edit.UseEllipsis=Yes")
```

**EditMask.property**

*Description*  
Settings that affect the appearance and behavior of columns with the EditMask edit style.

*Applies to*  
Column controls

*Syntax*  
PowerBuilder dot notation:

```
dw_control.Object.columnname.EditMask.property
```

*Describe and Modify argument:*

```
"columnname.EditMask.property { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The column with the EditMask edit style for which you want to get or set property values. You can specify the column name or a pound sign (#) and the column number.</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property for the column’s EditMask style. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to be assigned to the property. For EditMask properties, you cannot specify a DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for EditMask</th>
<th>Value</th>
</tr>
</thead>
</table>
| **AutoSkip** | Whether the EditMask will automatically skip to the next field when the maximum number of characters has been entered.  
Values are:  
Yes – Skip automatically.  
No – Do not skip automatically.  
Painter: AutoSkip option. |
| **CodeTable** | Whether the column has a code table.  
Values are:  
Yes – Code table defined.  
No – No code table defined.  
Painter: Code Table option. When selected, Display Value and DataValue are displayed for specifying code table entries. |
# DataWindow Object Properties

## Chapter 3

### DDCalendar
Whether a drop-down calendar control displays when a user clicks in a column with a Date or DateTime edit mask.

Values are:
- Yes – Drop-down calendar control displays.
- No – (Default) Drop-down calendar control does not display.

For Web DataWindows, to make sure that dates selected with the drop-down calendar option are displayed with the desired edit mask, you should specify that the Client Formatting option be included with the static JavaScript generated and deployed for the DataWindow. To conserve bandwidth, JavaScript for client formatting is not included by default.

If you do not include script for client formatting, the drop-down calendar will use a default edit mask to display the column data based on the client machine’s default localization settings.

**Painter:** Drop-down Calendar option.

### DDCal_AlignRight
Whether the drop-down calendar is aligned with the right side of the column.

Values are:
- Yes – Column is right aligned.
- No – (Default) Column is left aligned.

**Painter:** Drop Align Right option on Other page.

### DDCal_BackColor
The background color of the drop-down calendar. The default is Window Background. This property is not supported on the Vista operating system.

**Painter:** CalendarBackColor option on Other page.

### DDCal_TextColor
The color of text in the drop-down calendar. The default is Window Text. This property is not supported on the Vista operating system.

**Painter:** CalendarTextColor option on Other page.

### DDCal_TitleBackColor
The background color of the title in the drop-down calendar. The default is Highlight. This property is not supported on the Vista operating system.

**Painter:** CalendarTitleBackColor option on Other page.

### DDCal_TitleTextColor
The color of text in the title of the drop-down calendar. The default is Highlight Text. This property is not supported on the Vista operating system.

**Painter:** CalendarTitleTextColor option on Other page.

### DDCal_TrailingTextColor
The color of trailing text (days in the previous and next months) in the drop-down calendar. The default is Disabled Text. This property is not supported on the Vista operating system.

**Painter:** CalendarTrailingTextColor option on Other page.
### Property for EditMask

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FocusRectangle</td>
<td>Whether a dotted rectangle (the focus rectangle) will surround the current row of the column when the column has focus. Values are: Yes – (Default) Display the focus rectangle. No – Do not display the focus rectangle. Painter: Show Focus Rectangle option.</td>
</tr>
<tr>
<td>Mask</td>
<td>A string containing the edit mask for the column. Painter: Mask option.</td>
</tr>
<tr>
<td>ReadOnly</td>
<td>Whether the column is read-only. This property is valid only if EditMask.Spin is set to Yes. Values are: Yes – Do not allow the user to enter data; make the column read-only. No – (Default) Allow the user to enter data. Painter: Read Only option.</td>
</tr>
<tr>
<td>Required</td>
<td>Whether the column is required. Values are: Yes – It is required. No – It is not required. Painter: Required option.</td>
</tr>
<tr>
<td>Spin</td>
<td>Whether the user can scroll through a list of possible values for the column with a spin control. Values are: Yes – Display a spin control. No – (Default) Do not display a spin control. Painter: Spin Control option.</td>
</tr>
<tr>
<td>SpinIncr</td>
<td>An integer indicating the amount to increment the spin control’s values. The default for numeric values is 1; for dates, 1 year; and for time, 1 minute. Available for numeric, date, and time columns. For columns that are not numeric, date, or time, the spin control scrolls through values in an associated code table. If the EditMask.CodeTable property is No, the spin increment has no effect for these columns. Painter: Spin Increment option.</td>
</tr>
</tbody>
</table>
 CHAPTER 3  DataWindow Object Properties

Property for EditMask | Value
--- | ---
SpinRange | A string containing the maximum and minimum values for the column that will display in the spin control. The two values are separated by a tilde (~). This property is effective only if Style is EditMask. Available for numeric, date, and time columns.

Because the SpinRange string is within another quoted string, the tilde separator becomes four tildes in PowerBuilder, which reduces to a single tilde when parsed.

The format for the string is:

```
"EditMask.SpinRange = 'minval'~~~'maxval'
```

Painter: Spin Range group, Spin Min and Spin Max options.

UseEllipsis | Whether an ellipsis (three dots) displays when a column with the EditMask edit style contains character data that is too long for the display column in the DataWindow. The ellipsis does not display when the column has focus.

Values are:

- Yes – Truncate the data and add an ellipsis.
- No – Truncate the data. Do not add an ellipsis.

The property is ignored if you:

- Check Autosize Height on the Position page or set the Height.Autosize property in a script.
- Specify an expression for the Escapement property on the Font page or set the Font.Escapement property in a script to rotate the text.

The UseEllipsis DataWindow object property is not supported in Web Forms applications.

Painter: Use Ellipsis check box on the Format page.

UseFormat | Whether a Format Display mask is used for a column’s display. A Format Display mask is used only when the column does not have focus.

Values are:

- Yes – Use a Format Display mask.
- No – (Default) Do not use a Format Display mask.

Painter: Use Format option.

Usage | In the painter Select the control and set values in the Properties view, Edit tab, when Style is EditMask.

Examples

```powershell
setting = dw1.Describe("emp_status.EditMask.Spin")
dw1.Modify("empBonus.EditMask.SpinIncr=1000")
dw1.Modify("empBonus.EditMask.SpinRange='0~~~5000'")

string setting
setting = dw1.Object.emp_status.EditMask.Spin
dw1.Object.emp_bonus.EditMask.SpinIncr = 1000
dw1.Object.id.EditMask.SpinRange = "0~~~10"
```
**Elevation**

Description
The elevation in a 3D graph.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:

```
dw1.Object.col1.EditMask.UseEllipsis = Yes
dw1.Modify("col1.EditMask.UseEllipsis=Yes")
```

**Usage**

*In the painter* Select the control and set the value in the Properties view, General tab, Elevation scroll bar (enabled when a 3D graph type is selected).

**Examples**

```powershell
string setting
setting = dw1.Object.graph_1.Elevation
dw1.Object.graph_1.Elevation = 35

setting = dw1.Describe("graph_1.Elevation")
dw1.Modify("graph_1.Elevation=35")
dw1.Modify("graph_1.Elevation='10-tIf(...,20,30)'")
```

**EllipseHeight**

Description
The radius of the vertical part of the corners of a RoundRectangle.

Applies to
RoundRectangle controls

Syntax
PowerBuilder dot notation:

```
dw_control.Object.rectname.EllipseHeight
```

Describe and Modify argument:

```
"rectname.EllipseHeight { = ' integer ' }"
```
CHAPTER 3  DataWindow Object Properties

Usage

In the painter  Select the control and set the value in the Properties view, General tab.

Examples

string setting
setting = dw1.Object.rrect_1.EllipseHeight
dw1.Object.rrect_1.EllipseHeight = 35

setting = dw1.Describe("rrect_1.EllipseHeight")
dw1.Modify("rrect_1.EllipseHeight=35")
dw1.Modify("rrect_1.EllipseHeight='10-tIf(...,20,30)'"
)

**EllipseWidth**

Description  The radius of the horizontal part of the corners of a RoundRectangle.

Applies to  RoundRectangle controls

Syntax  PowerBuilder dot notation:

dw_control.Object.rrectname.EllipseWidth

Describe and Modify argument:

"rrectname.EllipseWidth { = 'integer' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rrectname</td>
<td>The name of the RoundRectangle control in the DataWindow for which you want to get or set the ellipse width.</td>
</tr>
<tr>
<td>integer</td>
<td>(exp) An integer specifying the radius of the horizontal part of the corners of a RoundRectangle in the DataWindow’s unit of measure. EllipseHeight can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage

In the painter  Select the control and set the value in the Properties view, General tab.
**Enabled**

**Examples**

```powerbuilder
string setting
setting = dw1.Object.rrect_1.EllipseWidth
dw1.Object.rrect_1.EllipseWidth = 35

setting = dw1.Describe("rrect_1.EllipseWidth")
dw1.Modify("rrect_1.EllipseWidth=35")
dw1.Modify("rrect_1.EllipseWidth='10-tIf(,...,20,30)'")
```

**Enabled**

**Description**
Determine whether a control in a DataWindow is enabled.

**Applies to**
Button, InkPicture controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.buttonname.Enabled
```

Describe and Modify argument:

```
"buttonname.Enabled { = 'value' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>buttonname</code></td>
<td>The name of the button that you want to enable or disable.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>Whether the button is enabled.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – (Default) The button is enabled.</td>
</tr>
<tr>
<td></td>
<td>No – The button is disabled.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter** Select the control and set the value in the Properties view, General tab, Enabled option.

When the Enabled check box is cleared, or the Enabled property is otherwise set to false, the button control is grayed and its actions are not performed.

**Examples**

```powerbuilder
dw1.Object.b_name.Enabled = "No"

setting = dw1.Describe("b_name.Enabled")
dw1.Modify("b_name.Enabled = 'No'")
```
Export.PDF.Distill.CustomPostScript

Description
Setting that enables you to specify the PostScript printer driver settings used when data is exported to PDF using the Distill! method.

Applies to
DataWindow objects

Syntax
PowerBuilder dot notation:

```
```

Describe and Modify argument:

```
"DataWindow.Export.PDF.Distill.CustomPostScript { = 'value ' }
```

Usage
The Distill! method performs a PostScript “print to file” before distilling to PDF. This property can be set to specify that you want to use a custom PostScript printer before you call the SaveAs method with PDF! as the SaveAsType or select File>Save Rows As with the file type PDF in the DataWindow painter.

Set this property if you want to use a PostScript printer driver for which you have set specific print options such as options for font and graphic handling. If this property is not set, a default PostScript printer driver specifically designed for distilling purposes is used.

This property has no effect if the Export.PDF.Method property is set to XSLFOP!.

In the Data Export tab in the Properties view for the DataWindow object, select PDF from the Format to Configure list and Distill! from the Method list, and then select Distill Custom PostScript.

Examples
This example specifies an HP LaserJet PostScript printer as the printer to be used to export PDF with customized settings, and saves the data to a file called custom.pdf:

```
int li_ret

```

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>(exp) Whether the printer specified in the DataWindow.Printer property is used when data is exported to PDF. Values are: • 1 – The printer specified in DataWindow.Printer is used for PDF export. • 0 – The default printer is used for PDF export (default).</td>
</tr>
</tbody>
</table>
Export.PDF.Method

```
dw1.Object.DataWindow.Printer = &
    "HP LaserJet 4Si/4Si MX PostScript"

dw1.Object.DataWindow.Export.PDF. &
    Distill.CustomPostScript='1'

li_ret = dw1.SaveAs("custom.pdf", PDF!, true)
```

This example uses Modify to set the PDF export properties and specify a network printer:

```
dw1.Modify("DataWindow.Export.PDF.Method = Distill!")
dw1.Modify("Printer = '\print-server\pr-18' ")
dw1.Modify &
    ("DataWindow.Export.PDF.Distill.CustomPostScript='1'")
```

See also  

Export.PDF.Method

Export.PDF.Method

**Description**

Setting that determines whether data is exported to PDF from a DataWindow object by printing to a PostScript file and distilling to PDF, or by saving in XSL Formatting Objects (XSL-FO) format and processing to PDF.

**Applies to**

DataWindow objects

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Export.PDF.Method
```

**Describe and Modify argument:**

```
"DataWindow.Export.PDF.Method { = 'value '}
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>A string specifying a value of the PDFMethod enumerated datatype</td>
</tr>
</tbody>
</table>

**Usage**

This property can be set to specify the method used to export data to PDF before you call the SaveAs method with PDF! as the SaveAsType or select File>Save Rows As with the file type PDF in the DataWindow painter. If this property is not set, the distill method is used by default.

**PDFMethod** is an enumerated datatype that can hold the following values:

<table>
<thead>
<tr>
<th>Enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distill!</td>
<td>0</td>
<td>Data is printed to a PostScript file and distilled to PDF (default).</td>
</tr>
<tr>
<td>XSLFOP!</td>
<td>1</td>
<td>Data is saved as XSL-FO and processed to PDF.</td>
</tr>
</tbody>
</table>
The distill method provides a robust solution that can save all types of DataWindow objects on the Windows platform. The XSL-FO method uses a platform-independent Java process, and is particularly useful for printing DataWindow objects in EAServer on a UNIX operating system.

**Saving as XSL-FO**
You can also save the data in a DataWindow object in XSL-FO format and customize the filters used to convert it to PDF and other output formats. To do so, use XSLFO! as the SaveAsType parameter when you call SaveAs, or select XSL-FO as the file type when you save rows in the DataWindow painter.

**Deployment requirements** If your application uses the distill method, you must distribute the GNU Ghostscript files and default PostScript printer driver and related files (if using the default printer) with your application. If your application uses the XSL-FO method, you must distribute Apache FOP files and the Java Runtime Environment (JRE) with your application. For more information, see the chapter on deploying your application in *Application Techniques*.

**In the painter** On the Data Export page in the Properties view for the DataWindow object, select PDF from the Format to Configure list and Distill! or XSLFOP! from the Method list.

**Examples**

This statement specifies that data is exported to PDF using XSL-FO:

```
dw1.Modify("DataWindow.Export.PDF.Method = XSLFOP! ")
```

**See also**

Export.PDF.Distill.CustomPostScript
Export.PDF.XSLFOP.Print

### Export.PDF.XSLFOP.Print

**Description** Setting that enables you to send a DataWindow object directly to a printer using platform-independent Java printing when using the XSL-FO method to export to PDF. This is an option of the Apache FOP processor.

**Applies to** DataWindow objects

**Syntax** PowerBuilder dot notation:

```
dw_control.Object.DataWindow.PDF.XSLFOP.Print
dw_control.Object.DataWindow.PDF.XSLFOP.Print { = 'value' }
```

DataWindow Reference 255
Export.XHTML.TemplateCount

### Parameter | Description
---|---
value | *(exp)* Whether the exported PDF is sent directly to the default printer.

Values are:
- Yes – The DataWindow object is exported to a PDF file and sent directly to a printer.
- No – The DataWindow object is exported to a PDF file but is not printed (default).

**Usage**

Set this property if you are using the XSL-FO method to export a DataWindow object to a PDF file and you want to send the PDF file directly to a printer. The PDF file is always printed to the default system printer. The DataWindow.Printer property setting is ignored.

This property has no effect if the Export.PDF.Method property is set to Distill!.

**In the painter**

On the Data Export page in the Properties view for the DataWindow object, select PDF from the Format to Configure list and XSLFOP! from the Method list, and then select Print Using XSLFOP.

**Examples**

This example specifies the XSLFOP! method for PDF export, sets the XSLFOP.Print property, and saves the data to a file called *printed.pdf*, which is sent directly to the default printer:

```powershell
int li_ret
dw1.Object.DataWindow.Export.PDF.Method = XSLFOP!
dw1.Object.DataWindow.Export.PDF.xslfop.print='Yes'
li_ret = dw1.SaveAs("printed.pdf", PDF!, true)
```

**See also**

Export.PDF.Method

---

**Export.XHTML.TemplateCount**

**Description**

The number of XHTML export templates associated with a DataWindow object.

**Applies to**

DataWindow objects

**Syntax**

PowerBuilder dot notation:

```powershell
dw_control.Object.DataWindow.Export.XHTML.TemplateCount
```

**Describe argument:**

"DataWindow.Export.XHTML.TemplateCount"
Usage

This property is used to get a count of the XHTML export templates associated with a DataWindow object. It returns a long specifying the number of XHTML export templates previously saved in the DataWindow painter for the specified DataWindow object. The count is used with the DataWindow.Export.XHTML.Template[].Name property to enable an application to select an export template at runtime.

Examples

This code in the open event of a window uses the TemplateCount property to get the number of templates associated with dw1. It then uses the number returned as the upper limit in a FOR loop that populates a drop-down list box with the template names, using the DataWindow.Export.XHTML.Template[].Name property.

```powershell
string ls_template_name
long l_template_count, i

l_template_count = Long &
    (dw1.Object.DataWindow.Export.XHTML.TemplateCount)

for i=1 to l_template_count
    ls_template_name = &
        dw1.Object.DataWindow.Export.XHTML.Template[i].Name
    ddb_1.AddItem(ls_template_name)
next

Before generating the XHTML, set the export template using the text in the drop-down list box:

dw1.Object.DataWindow.Export.XHTML.UseTemplate= ddb_1.text
```

See also

Export.XHTML.Template[].Name
Export.XHTML.UseTemplate

Export.XHTML.Template[].Name

Description

The name of an XHTML export template associated with a DataWindow object.

Applies to

DataWindow objects

Syntax

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Export.XHTML.Template[ num ].Name
```
**Export.XHTML.UseTemplate**

**Description**
Setting that optionally controls the logical structure of the XHTML generated by a DataWindow object from a DataWindow data expression using dot notation.

**Applies to**
DataWindow objects

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.DataWindow.Export.XHTML.UseTemplate
```

**Usage**
This property uses a template defined in the DataWindow painter to specify the logical structure and attribute overrides that PowerBuilder should use to generate XHTML from a DataWindow object. It is designed to be used with the data expression for the DataWindow object, and should be set before a data expression statement.

**Parameter** | **Description**
--- | ---
`value` | `(exp)` A string specifying the name of an XHTML export template previously saved in the DataWindow painter for the specified DataWindow object

---

**Export.XHTML.UseTemplate**

**Usage**
This property returns the names of the XHTML export templates associated with a DataWindow object by index. The index can range from 1 to the value of the `DataWindow.Export.XHTML.TemplateCount` property. The order reflects the serialized storage order of all templates, which is a read-only setting. These properties, with `DataWindow.Export.XHTML.UseTemplate`, enable an application to select an export template dynamically at runtime.

**Examples**
See `Export.XHTML.TemplateCount`.

**See also**
`Export.XHTML.TemplateCount`  
`Export.XHTML.UseTemplate`
In the painter In the Data Export tab in the Properties view for the DataWindow object, select XHTML from the Format to Configure list and select a template from the Use Template list.

Examples

This example stores the name of the export template used in dw1 in the string ls_template. If no template is selected in dw1, an empty string is returned.

```powerbuilder
string ls_template_name
ls_template_name =
dw1.Describe("DataWindow.Export.XHTML.UseTemplate")
```

This example sets the name of the current XHTML export template used in dw1 to t_report. If t_report does not exist, the current template is not changed.

```powerbuilder
dw1.Modify("DataWindow.Export.XHTML.UseTemplate = 't_report' ")
```

See also

Export.XHTML.TemplateCount
Export.XHTML.Template[ ].Name

Export.XML.HeadGroups

Description Setting that causes elements, attributes, and all other items above the Detail Start element in an XML export template for a group DataWindow to be iterated for each group in the exported XML.

Applies to

DataWindow objects

Syntax

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Export.XML.HeadGroups
```

Describe and Modify argument:

```
"DataWindow.Export.XML.HeadGroups { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>(exp) Whether the contents of the header section in an export template iterate in the generated XML. Values are: • Yes – The header section is repeated for each group (default). • No – The header section is not repeated.</td>
</tr>
</tbody>
</table>
**Export.XML.IncludeWhitespace**

### Usage
This property must be set for group DataWindow objects if you want elements and other items added to the header section of an XML export template to be repeated before each group in the exported XML. For DataWindow objects with multiple groups, each XML fragment in the header section between a Group Header element and the next Group Header element or Detail Start element is iterated.

**In the painter** In the Data Export tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select Iterate header for Groups.

**Examples**
```
dw1.Object.DataWindow.Export.XML.HeadGroups = "Yes"
dw1.Modify("DataWindow.Export.XML.HeadGroups = 'No' ")
```

### Description
Setting that determines whether the XML document is formatted by inserting whitespace characters (carriage returns, linefeeds, tabs, and spacebar spaces).

### Applies to
DataWindow objects

### Syntax
PowerBuilder dot notation:
```
dw_control/Object.DataWindow.Export.XML.IncludeWhitespace
```

**Describe and Modify** argument:
```
"DataWindow.Export.XML.IncludeWhitespace { = 'value' }"
```

### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| value     | (exp) Whether the generated XML is formatted with whitespace characters. Values are:  
  • Yes – Whitespace characters are inserted.  
  • No – Whitespace characters are not inserted (default). |

### Usage
This property should be set before you export a DataWindow object if you want to view or verify the exported XML using a text editor.

**In the painter** In the Data Export tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select Include Whitespace.

**Examples**
```
dw1.Object.DataWindow.Export.XML.IncludeWhitespace = "No"
dw1.Modify("DataWindow.Export.XML.IncludeWhitespace = 'Yes' ")
```
Export.XML.MetaDataType

**Description**
Setting that controls the type of metadata generated with the XML exported from a DataWindow object using the SaveAs method or a .Data.XML expression.

**Applies to**
DataWindow objects

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Export.XML.MetaDataType
```

**Describe and Modify argument:**

```
"DataWindow.Export.XML.MetaDataType { = 'value' }"
```

**Parameter** | **Description**
--- | ---
value | (exp) A string specifying a value of the Export.XML.MetaDataType enumerated datatype

**Usage**
This property must be set to specify the type of metadata generated before you call the SaveAs method with XML! as the SaveAsType to save data as an XML document, or use the .Data.XML expression to save data as an XML string. The metadata is saved into the exported XML itself or into an associated file, depending on the value of the Export.XML.SaveMetaData property.

The Export.XML.MetaDataType property is an enumerated datatype that can hold the following values:

<table>
<thead>
<tr>
<th>Enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNone!</td>
<td>0</td>
<td>Metadata (XML Schema or DTD) is not generated when XML is exported</td>
</tr>
<tr>
<td>XMLSchema!</td>
<td>1</td>
<td>XML Schema is generated when XML is exported</td>
</tr>
<tr>
<td>XMLDTD!</td>
<td>2</td>
<td>DTD is generated when XML is exported</td>
</tr>
</tbody>
</table>

If the data item for a column is null or an empty string, an empty element is created when you export XML. If you select XMLSchema!, child elements with null data items are created with the content "xsi:nil='true'".

**In the painter**
In the Data Export tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select a value from the Meta Data Type list.

**Examples**
This statement specifies that no metadata will be generated when the DataWindow is exported to XML:

```
"DataWindow.Export.XML.MetaDataType { = 'XMLNone!' }"
```
Export.XML.SaveMetaData

These statements export the contents of dw1 to the file c:\myxml.xml using the XML export template called t_schema, and generate an external XML schema file at c:\myxml.xsd:

```powershell
dw1.Modify("DataWindow.Export.XML.UseTemplate = 't_schema'")
dw1.Modify("DataWindow.Export.XML.MetaDataType = 1")
dw1.Modify("DataWindow.Export.XML.SaveMetaData = 1")
dw1.SaveAs("c:\myxml.xml", XML!, false)
```

See also Export.XML.SaveMetaData

Export.XML.SaveMetaData

Description Setting that controls the storage format for the metadata generated with the XML exported from a DataWindow object using the SaveAs method or a .Data.XML expression.

Applies to DataWindow objects

Syntax PowerBuilder dot notation:

```powershell
dw_control.Object.DataWindow.Export.XML.SaveMetaData
```

Describe and Modify argument:

```powershell
"DataWindow.Export.XML.SaveMetaData { = 'value' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| value     | (exp) A string specifying a value of the Export.XML.SaveMetaData enumerated datatype

Usage This property must be set to specify how to store the generated metadata before you call the SaveAs method with XML! as the SaveAsType to save data as an XML document, or use the .Data.XML expression to save data as an XML string. The metadata can be saved into the exported XML document or string or into an associated file.

Note
If Export.XML.MetaDataType is set to XMLNone!, the value of the Export.XML.SaveMetaData property is not used.
The Export.XML.SaveMetaData property is an enumerated datatype that can hold the following values:

<table>
<thead>
<tr>
<th>Enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MetaDataInternal!</td>
<td>0</td>
<td>The metadata is saved into the generated XML document or string. To save metadata using the .Data.XML expression syntax, you must use this value.</td>
</tr>
<tr>
<td>MetaDataExternal!</td>
<td>1</td>
<td>With the SaveAs method, metadata is saved as an external file with the same name as the XML document but with the extension .xsd (for XMLSchema type) or .dtd (for XMLDTD type). A reference to the name of the metadata file is included in the output XML document. With .Data.XML, no metadata is generated in the XML string.</td>
</tr>
</tbody>
</table>

**In the painter** In the Data Export tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select a value from the Save Meta Data list.

**Examples**

```
   dw1.Object.DataWindow.Export.XML.SaveMetaData = 0
   dw1.Modify("DataWindow.Export.XML.SaveMetaData = MetaDataExternal!")
```

**See also**

Export.XML.MetaDataType

---

**Export.XML.TemplateCount**

**Description**

The number of XML export templates associated with a DataWindow object.

**Applies to**

DataWindow objects

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Export.XML.TemplateCount
```

Describe argument:

"DataWindow.Export.XML.TemplateCount"
**Export.XML.Template[ ].Name**

**Usage**

This property is used to get a count of the XML export templates associated with a DataWindow object. It returns a long specifying the number of XML export templates previously saved in the DataWindow painter for the specified DataWindow object. The count is used with the DataWindow.Export.XML.Template[ ].Name property to enable an application to select an export template at runtime.

**Examples**

This code in the open event of a window uses the TemplateCount property to get the number of templates associated with dw1. It then uses the number returned as the upper limit in a FOR loop that populates a drop-down list box with the template names, using the DataWindow.Export.XML.Template[ ].Name property.

```powerbuilder
string ls_template_count, ls_template_name
long i

ls_template_count=dw1.Describe
("DataWindow.Export.XML.TemplateCount")

for i=1 to Long(ls_template_count)
  ls_template_name=
    dw1.Object.DataWindow.Export.XML.Template[i].Name
  ddb_1.AddItem(ls_template_name)
next

Before generating the XML, set the export template using the text in the drop-down list box:

dw1.Object.DataWindow.Export.XML.UseTemplate=
  ddb_1.text
```

**See also**

Export.XML.Template[ ].Name
Export.XML.UseTemplate

---

**Export.XML.Template[ ].Name**

**Description**

The name of an XML export template associated with a DataWindow object.

**Applies to**

DataWindow objects

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Export.XML.Template[num ].Name
```

**Describe argument:**

"DataWindow.Export.XML.Template[num ]Name"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num</td>
<td>(exp) A long specifying the index of the export template</td>
</tr>
</tbody>
</table>
CHAPTER 3 DataWindow Object Properties

DataWindow Reference 265

Usage
This property is used to get the names of the XML export templates associated with a DataWindow object. It returns a string specifying the name of an export template previously saved in the DataWindow painter for the specified DataWindow object. The property is used with the DataWindow.Export.XML.TemplateCount property to enable an application to select an export template at runtime.

Examples
See Export.XML.TemplateCount.

See also
Export.XML.TemplateCount
Export.XML.UseTemplate

Export.XML.UseTemplate

Description
Setting that optionally controls the logical structure of the XML exported from a DataWindow object using the SaveAs method or the .Data.XML property.

Applies to
DataWindow objects

Syntax
PowerBuilder dot notation:

dw_control.Object.DataWindow.Export.XML.UseTemplate

Describe and Modify argument:

"DataWindow.Export.XML.UseTemplate { = 'value' }"

Parameter | Description
--- | ---
value | (exp) A string specifying the name of an export template previously saved in the DataWindow painter for the specified DataWindow object

Usage
This property should be set to specify the logical structure of the XML generated before you call the SaveAs method with XML! as the SaveAsType to save data as an XML document, or use the .Data.XML expression to save data as an XML string.

In the painter In the Data Export tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select a template from the Use Template list.

Examples
This example stores the name of the export template used in dw1 in the string ls_template. If no template is selected in dw1, an empty string is returned.

```powerbuilder
string ls_template_name
ls_template_name =
dw1.Describe("DataWindow.Export.XML.UseTemplate")
```
Expression

This example sets the name of the current XML export template used in dw1 to t_report. If t_report does not exist, the current template is not changed.

```
dw1.Modify("DataWindow.Export.XML.UseTemplate = 't_report' ")
```

See also

Export.XML.MetaDataType
Export.XML.SaveMetaData

Expression

Description

The expression for a computed field control in the DataWindow. The expression is made up of calculations and DataWindow expression functions. The DataWindow evaluates the expression to get the value it will display in the computed field.

Applies to

Computed field controls

Syntax

PowerBuilder dot notation:

```
dw_control.Object.computename.Expression
```

Describe and Modify argument:

```
"computename.Expression { = 'string' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>computename</td>
<td>The name of the computed field control in the DataWindow for which you want to get or set the expression</td>
</tr>
<tr>
<td>string</td>
<td>A string whose value is the expression for the computed field</td>
</tr>
</tbody>
</table>

Usage

**In the painter** Select the control and set the value in the Properties view, General tab, Expression option. The More button displays the Modify Expression dialog, which provides help in specifying the expression. The Verify button tests the expression.

Examples

```
setting = dw1.Object.comp_1.Expression
dw1.Object.comp_1.Expression = "avg(salary for all)"
```

```
setting = dw1.Describe("comp_1.Expression")
dw1.Modify("comp_1.Expression='avg(salary for all)'")
```
Filename

The file name containing the image for a Picture or Button control in the DataWindow. If no image is specified for a Button control, only text is used for the button label.

Applies to
Picture and Button controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Filename

Describe and Modify argument:
"controlname.Filename = 'filestring'"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the Picture or Button control in the DataWindow for which you want to get or set the image file name.</td>
</tr>
<tr>
<td>filestring</td>
<td>(exp) A string containing the name of the file that contains the image. Filestring can be a quoted DataWindow expression. Button pictures can be BMP, GIF, or JPEG files. You can use a URL instead of a full path name, and if you set the HTMLGen.ResourceBase property to the URL address, you need to specify only a relative file name for this string. If you include the name of the file containing the image in the executable for the application, PowerBuilder will always use that image; you cannot use Modify to change the image.</td>
</tr>
</tbody>
</table>

Usage
In the painter For a Picture control, select the control and set the value in the Properties view, General tab, File Name option. For a Button control, select the control and set the value in the Properties view, General tab, Picture File option. The Action Default Picture check box must be cleared to set the value for the picture file.

Examples
Example for a Picture control:

setting = dw1.Object.bitmap_1.Filename
dw1.Object.bitmap_1.Filename = "exclaim.bmp"

setting = dw1.Describe("bitmap_1.Filename")
dw1.Modify("bitmap_1.Filename='exclaim.bmp'")

Example for a Button control:

dw1.Object.b_name.FileName = "logo.gif"
ls_data = dw1.Describe("b_name.FileName")
dw1.Modify("b_name.FileName = 'logo.jpg'")

See also
DefaultPicture
**FirstRowOnPage**

**Description**
The first row currently visible in the DataWindow.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.FirstRowOnPage
```

**Describe argument:**

```
"DataWindow.FirstRowOnPage"
```

**Examples**

```
string setting
setting = dw1.Object.DataWindow.FirstRowOnPage
setting = dw1.Describe("DataWindow.FirstRowOnPage")
```

**Font.Bias**

**Description**
The way fonts are manipulated in the DataWindow at runtime.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Font.Bias
```

**Describe and Modify argument:**

```
"DataWindow.Font.Bias { = biasvalue }
```

**Parameter** | **Description**
--- | ---
`biasvalue` | An integer indicating how the fonts will be manipulated at execution. *Biasvalue* cannot be a DataWindow expression. Values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>As display fonts</td>
</tr>
<tr>
<td>1</td>
<td>As printer fonts</td>
</tr>
<tr>
<td>2</td>
<td>Neutral; no manipulation will take place</td>
</tr>
</tbody>
</table>

**Examples**

```
string setting
setting = dw1.Object.DataWindow.Font.Bias
dw1.Object.DataWindow.Font.Bias = 1

setting = dw1.Describe("DataWindow.Font.Bias")
dw1.Modify("DataWindow.Font.Bias=1")
```
Font.property

Description: Settings that control the appearance of fonts within a DataWindow, except for graphs, which have their own settings (see DispAttr).

Applies to: Button, Column, Computed Field, GroupBox, and Text controls

Syntax: PowerBuilder dot notation:

```
dw_control.Object.controlname.Font.property
```

SyntaxFromSql:

```
Column(Font.property = value)
    Text(Font.property = value)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>controlname</code></td>
<td>The name of a column, computed field, or text control for which you want to get or set font properties. For a column, you can specify the column name or a pound sign (#) followed by the column number. When you generate DataWindow syntax with SyntaxFromSql, the Font settings apply to all columns or all text controls.</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property of the text. The properties and their values are listed in the table below.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to be assigned to the property. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for Font</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CharSet</td>
<td><code>(exp)</code> An integer specifying the character set to be used. Values are: 0 – ANSI 1 – The default character set for the specified font 2 – Symbol 128 – Shift JIS 255 – OEM Painter: Font tab, CharSet option.</td>
</tr>
<tr>
<td>Escapement</td>
<td><code>(exp)</code> An integer specifying the rotation for the baseline of the text in tenths of a degree. For example, a value of 450 rotates the text 45 degrees. 0 is horizontal. Painter: Font tab, Escapement option.</td>
</tr>
<tr>
<td>Face</td>
<td><code>(exp)</code> A string specifying the name of the font face, such as Arial or Courier. Painter: Font tab, FaceName option or StyleBar.</td>
</tr>
</tbody>
</table>
### Property for Font

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
</table>
| Family         | *(exp)* An integer specifying the font family (Windows uses both face and family to determine which font to use).  
|                | Values are:  
|                | 0 – AnyFont  
|                | 1 – Roman  
|                | 2 – Swiss  
|                | 3 – Modern  
|                | 4 – Script  
|                | 5 – Decorative  
|                | Painter: Font tab, Family option.                                                      |
| Height         | *(exp)* An integer specifying the height of the text in the unit measure for the DataWindow. To specify size in points, specify a negative number.  
|                | Painter: Font tab, Size option (specified in points) or StyleBar or Expressions tab.    |
| Italic         | *(exp)* Whether the text should be italic. The default is no.  
|                | Painter: Font tab, Italic check box or StyleBar.                                        |
| Pitch          | *(exp)* The pitch of the font.  
|                | Values are:  
|                | 0 – The default pitch for your system  
|                | 1 – Fixed  
|                | 2 – Variable  
|                | Painter: Font tab, Pitch option.                                                       |
| Strikethrough  | *(exp)* Whether the text should be crossed out. The default is no.  
|                | Painter: Font tab, Strikeout check box.                                                 |
| Underline      | *(exp)* Whether the text should be underlined. The default is no.  
|                | Painter: Font tab, Underline check box or StyleBar.                                    |
| Weight         | *(exp)* An integer specifying the weight of the text; for example, 400 for normal or 700 for bold.  
|                | Painter: Set indirectly using the Font tab, Bold option or the StyleBar, Bold button.   |
| Width          | *(exp)* An integer specifying the average character width of the font in the unit of measure specified for the DataWindow. Width is usually unspecified, which results in a default width based on the other properties.  
|                | Painter: Set indirectly using the font selection.                                       |

**Usage**

**In the painter**  
Select the control and set the value using the:  
- Properties view, Font tab  
- For some font settings, StyleBar
Examples

- `dw1.Object.emp_name_t.Font.Face`
- `dw1.Object.emp_name_t.Font.Face = "Arial"`
- `dw1.Describe("emp_name_t.Font.Face")`
- `dw1.Modify("emp_name_t.Font.Face='Arial'")`

See also
- Transparency (columns and controls)

**Footer.property**

See Bandname.property.

**Format**

**Description**
The display format for a column.

You can use the `GetFormat` and `SetFormat` methods instead of `Describe` and `Modify` to get and change a column’s display format. The advantage to using `Modify` is the ability to specify an expression.

**Applies to**
- Column and Computed Field controls

**Syntax**
- PowerBuilder dot notation:
  
  \[ dw_{control}.Object.controlname.Format \]

  `Describe` and `Modify` argument:

  \[ "controlname.Format { = ' value' }" \]

**Parameter** | **Description**
--- | ---
`controlname` | The name of the column or computed field for which you want to get or set the display format.
`value` | `(exp)` A string specifying the display format. See the *Users Guide* for information on constructing display formats. *Value* can be a quoted DataWindow expression.

**Usage**

**In the painter**
Select the control and set the value in the Properties view, Format tab.

If you want to add text to a numeric display format and use a color attribute, you must include the escape character (\) before each literal in the mask. For example:

\[ \text{[red]}\D\e\p\t\:\#\#\# \]
Gradient.property

Examples

```
setting = dw1.Object.phone.Format
dw1.Object."phone.Format = "[red](@@@)@@@-@@@@;'None''

setting = dw1.Describe("phone.Format")
dw1.Modify( &
   "phone.Format='[red](@@@)@@@-@@@@;'None''"
)
```

See also

GetFormat function in the PowerScript Reference
SetFormat function in the PowerScript Reference

Gradient.property

Description

Settings that control the gradient display in a DataWindow object. Gradient display properties are not supported in Web Forms applications or in RichText, Graph, or OLE DataWindow presentation styles.

Applies to

DataWindows

Syntax

PowerBuilder dot notation:

```
dw_control.Object.datawindow.gradient.property
```

Describe and Modify argument:

```
"DataWindow.gradient.property { = value }"
```

Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for the gradient. Properties and their settings are listed in the table that follows.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. For gradient properties, value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for Gradient</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Angle</td>
<td>An integer indicating the angle in degrees (values are 0 to 360) used to offset the color and transparency gradient. This property is used only when datawindow.brushmode takes values of 3 or 4. Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Color</td>
<td>The gradient color of the DataWindow. This property is only in effect when datawindow.brushmode takes values 1 through 5. Painter: Background tab, Gradient group</td>
</tr>
<tr>
<td>Property for Gradient</td>
<td>Value</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------</td>
</tr>
<tr>
<td>Focus</td>
<td>An integer in the range 0 to 100, specifying the distance (as a percentage) from the center where the background color is at its maximum. (For example, if the radial gradient is used and the value is set to 0, the color will be at the center of the background; if the value is set to 100, the color will be at the edges of the background.)</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group</td>
</tr>
<tr>
<td>Repetition.Mode</td>
<td>Specifies the mode for determining the number of gradient transitions.</td>
</tr>
<tr>
<td></td>
<td>Permitted values and their meanings are:</td>
</tr>
<tr>
<td></td>
<td>• 0 Gradient.repetition.count determines the number of gradient transitions</td>
</tr>
<tr>
<td></td>
<td>• 1 Gradient.repetition.length determines the number of gradient transitions</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Repetition.Count</td>
<td>An integer specifying the number of gradient transitions for background color and transparency. A value of 0 indicates 1 transition. A value of 3 indicates 4 transitions. This property is used only when the datawindow.brushmode property takes values from 1 to 4 and when the when the datawindow.gradient.repetition.mode value is 0 (by count). The maximum is 10,000.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Repetition.Length</td>
<td>A long specifying the number of gradient transitions. This property is used only when the datawindow.gradient.repetition.mode property takes the value of 1 (by length). The units for the length that you assign for gradient transitions are set by the datawindow.units property.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group.</td>
</tr>
<tr>
<td>Scale</td>
<td>An integer in the range 0 to 100 specifying the rate of transition to the gradient color (as a percentage).</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group</td>
</tr>
<tr>
<td>Spread</td>
<td>An integer in the range 0 to 100 indicating the contribution of the second color to the blend (as a percentage).</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group</td>
</tr>
<tr>
<td>Transparency</td>
<td>An integer in the range 0 to 100, where 0 means that the secondary (gradient) background is opaque and 100 that it is completely transparent. The gradient defines transitions between the primary and secondary transparency settings.</td>
</tr>
<tr>
<td></td>
<td>Painter: Background tab, Gradient group</td>
</tr>
</tbody>
</table>

**Usage**

In the painter  Select the DataWindow object and set the value on the Background tab of the Properties view.

If you save to an EMF or WMF, the properties on the Background tab are not saved with the DataWindow.
GraphType

Examples

```
string ls_data
ls_data = dw_1.Object.datawindow.brushmode
dw_1.Object.datawindow.Brushmode = 5
ls_data = dw_1.Describe("datawindow.brushmode")
dw_1.Modify("datawindow.Brushmode=6")
dw_1.Modify("datawindow.Gradient.Transparency=75")
```

See also

Brushmode
Picture.property

GraphType

Description
The type of graph, such as bar, pie, column, and so on.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:
```
dw_control.Object.graphname.GraphType
```

Describe and Modify argument:
```
"graphname.GraphType { = 'typeinteger'}"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The graph control for which you want to get or change the type.</td>
</tr>
<tr>
<td>typeinteger</td>
<td>(exp) An integer identifying the type of graph in the DataWindow object. Type integer can be a quoted DataWindow expression. Values are:</td>
</tr>
<tr>
<td>1 – Area</td>
<td>10 – ColStacked</td>
</tr>
<tr>
<td>2 – Bar</td>
<td>11 – ColStacked3DObj</td>
</tr>
<tr>
<td>3 – Bar3D</td>
<td>12 – Line</td>
</tr>
<tr>
<td>4 – Bar3DObj</td>
<td>13 – Pie</td>
</tr>
<tr>
<td>5 – BarStacked</td>
<td>14 – Scatter</td>
</tr>
<tr>
<td>6 – BarStacked3DObj</td>
<td>15 – Area3D</td>
</tr>
<tr>
<td>7 – Col</td>
<td>16 – Line3D</td>
</tr>
<tr>
<td>8 – Col3D</td>
<td>17 – Pie3D</td>
</tr>
<tr>
<td>9 – Col3DObj</td>
<td></td>
</tr>
</tbody>
</table>

Usage
In the painter Select the control and set the value in the Properties view, General tab.

Examples
```
string setting
setting = dw1.Object.graph_1.GraphType
dw1.Object.graph_1.GraphType = 17
```
setting = dw1.Describe("graph_1.GraphType")
dw1.Modify("graph_1.GraphType=17")

**Grid.ColumnMove**

**Description**
Whether the user can rearrange columns by dragging.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

Describe and Modify argument:

"DataWindow.Grid.ColumnMove { = value }

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether the user can rearrange columns.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – The user can drag columns.</td>
</tr>
<tr>
<td></td>
<td>No – The user cannot drag columns.</td>
</tr>
</tbody>
</table>

**Usage**
**In the painter**
Select the DataWindow object by deselecting all controls; then set the value in the Properties view, General tab, Grid group, Column Moving check box (available when the presentation style is Grid, Crosstab, or TreeView with the Grid Style option selected).

**Examples**

string setting
dw1.Object.DataWindow.Grid.ColumnMove = No

setting = dw1.Describe("DataWindow.Grid.ColumnMove")
dw1.Modify("DataWindow.Grid.ColumnMove=No")

**Grid.Lines**

**Description**
The way grid lines display and print in a DataWindow whose presentation style is Grid, Crosstab, or TreeView.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

dw_control.Object.DataWindow.Grid.Lines
GroupBy

**Description**
A comma-separated list of the columns or expressions that control the grouping of the data transferred from the DataWindow to the OLE object. When there is more than one grouping column, the first one is the primary group and the columns that follow are nested groups.

**Applies to**
OLE Object controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.olecontrolname.GroupBy
```

Describe and Modify argument:
```
"olecontrolname.GroupBy { = columnlist }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>olecontrolname</td>
<td>The name of the OLE Object control for which you want to get or set the grouping columns.</td>
</tr>
</tbody>
</table>
Usage

Target and Range also affect the data that is transferred to the OLE object.

**In the painter** Select the control and set the value in the Properties view, Data tab, Group By option.

### Examples

```python
ls_data = dw1.Object.ole_report.GroupBy
dw1.Object.ole_report.GroupBy = "emp_state, emp_office"
dw1.Object.ole_report.GroupBy = "year"
ls_data = dw1.Describe("ole_report.GroupBy")
dw1.Modify("&
    ole_report.GroupBy='emp_state, emp_office'")
dw1.Modify("ole_report.GroupBy='year'")
```

---

**Header_Bottom_Margin**

**Description**

The size of the bottom margin of the DataWindow’s header area.

Header_Bottom_Margin is meaningful only when type is Grid or Tabular.

**Applies to**

Style keywords

**Syntax**

SyntaxFromSql:

```
Style ( Header_Bottom_Margin = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the size of the bottom margin of the header area in the units specified for the DataWindow. The bottom margin is the distance between the bottom of the header area and the last line of the header.</td>
</tr>
</tbody>
</table>

**Examples**

```python
SQLCA.SyntaxFromSQL(sqlstring, &
    'Style(...Header_Bottom_Margin = 25 ...)', &
    errstring)
```

---

**Header_Top_Margin**

**Description**

The size of the top margin of the DataWindow’s header area.

Header_Top_MARGIN is meaningful only when type is Grid or Tabular.
Header.property

Applies to Style keywords
Syntax SyntaxFromSql:
   Style ( Header_Top_Margin = value )

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the size of the top margin of the header area in the units specified for the DataWindow. The top margin is the distance between the top of the header area and the first line of the header.</td>
</tr>
</tbody>
</table>

Examples SQLCA.SyntaxFromSQL(sqlstring, & 'Style(...Header_Top_Margin = 500 ...)', errstring)

---

Header.property

See Bandname.property.

Header.#.property

See Bandname.property.

Height

Description The height of a control in the DataWindow.
Applies to Button, Column, Computed Field, Graph, GroupBox, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls
Syntax PowerBuilder dot notation:
   dw_control.Object.controlname.Height

Describe and Modify argument:
   "controlname.Height { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The control within the DataWindow whose height you want to get or set.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) An integer specifying the height of the control in the unit of measure specified for the DataWindow. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage In the painter Select the control and set the value in the Properties view. Position tab.
CHAPTER 3      DataWindow Object Properties

Examples

string setting
setting = dw1.Object.empname.Height
dw1.Object.empname.Height = 50
setting = dw1.Describe("empname.Height")
dw1.Modify("empname.Height=50")

Height.AutoSize

Description
Whether the control’s width should be held constant and its height adjusted so
that all the data is visible. This property is for use with read-only controls and
printed reports. It should not be used with data entry fields or controls.

Applies to
Column, Computed Field, Report, and Text controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Height.AutoSize

Describe and Modify argument:
"controlname.Height.AutoSize { = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The control for which you want to get or set the AutoSize property.</td>
</tr>
<tr>
<td>value</td>
<td>Whether the width or height of the control will be adjusted to display all the data. The height is limited to what can fit on the page. Values are: No – Use the height defined in the painter. Yes – Calculate the height so that all the data is visible.</td>
</tr>
</tbody>
</table>

Usage

In the painter
Select the control and set the value in the Properties view, Position tab, Autosize Height check box.

Minimum height
The height of the column, computed field, or text will never be less than the minimum height (the height selected in the painter).

When the band has Autosize Height set to true, you should avoid using the RowHeight DataWindow expression function to set the height of any element in the row. Doing so can result in a logical inconsistency between the height of the row and the height of the element. For more information, see the RowHeight function description.

Examples

string setting
setting = dw1.Object.empname.Height.AutoSize
Help.property

```powerbuilder
dw1.Object.empname.Height.AutoSize = "Yes"
setting = dw1Describew(empname.Height.AutoSize"
dw1.Modify("empname.Height.AutoSize=Yes")
```

See also Bandname.property

**Help.property**

**Description**
Settings for customizing the Help topics associated with DataWindow dialog boxes.

For more information about Help, see the ShowHelp function in the PowerScript Reference.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Help.property
```

**Describe and Modify argument:**

```
"DataWindow.Help.property \{ = value \}"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>property</strong></td>
<td>A property for specifying DataWindow Help. Help properties and their settings are listed in the table below. The File property must have a valid file name before the rest of the Help property settings can become valid.</td>
</tr>
<tr>
<td><strong>value</strong></td>
<td>The value to be assigned to the property. For Help properties, value cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for Help</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command</strong></td>
<td>An integer specifying the type of Help command that is specified in the following <strong>TypeID</strong> properties. Values are: 0 – Index 1 – TopicID 2 – Search keyword</td>
</tr>
<tr>
<td><strong>File</strong></td>
<td>A string containing the fully qualified name of the compiled Help file (for example, C:\proj\MYHELP.HLP). When this property has a value, Help buttons display on the DataWindow dialog boxes at runtime.</td>
</tr>
<tr>
<td><strong>TypeID</strong></td>
<td>A string specifying the default Help command to be used when a Help topic is not specified for the dialog using one of the following eight dialog-specific properties listed in this table.</td>
</tr>
</tbody>
</table>
CHAPTER 3  DataWindow Object Properties

Property for Help | Value
--- | ---
TypeID. ImportFile | A string specifying the Help topic for the Import File dialog box, which might display when the ImportFile method is called in code.
TypeID.Retrieve. Argument | A string specifying the Help topic for the Retrieval Arguments dialog box, which displays when retrieval arguments expected by the DataWindow’s SELECT statement are not specified for the Retrieve method in code.
TypeID.Retrieve. Criteria | A string specifying the Help topic for the Prompt for Criteria dialog box, which displays when the Criteria properties have been turned on for at least one column and the Retrieve method is called in code.
TypeID.SaveAs | A string specifying the Help topic for the Save As dialog box, which might display when the SaveAs method is called in code.
TypeID. SetCrosstab | A string specifying the Help topic for the Crosstab Definition dialog box, which might display when the CrosstabDialog method is called in code.
TypeID.SetFilter | A string specifying the Help topic for the Set Filter dialog box, which might display when the SetFilter and Filter methods are called in code.
TypeID.SetSort | A string specifying the Help topic for the Set Sort dialog box, which might display when the SetSort and Sort methods are called in code.
TypeID. SetSortExpr | A string specifying the Help topic for the Modify Expression dialog, which displays when the user double-clicks on a column in the Set Sort dialog.

Usage  | In the painter  Can be set only in code, not in the painter.

Examples

```PowerBuilder
class string setting

setting = dw1.Describe("DataWindow.Help.Command")
dw1.Modify("DataWindow.Help.File='myhelp.hlp'")
dw1.Modify("DataWindow.Help.Command=1")
dw1.Modify("DataWindow.Help.TypeID.SetFilter = 'filter_topic'")
dw1.Modify("DataWindow.Help.TypeID.Retrieve.Criteria = 'criteria_topic'")
```

HideGrayLine
Description  | Shows or hides a gray line to indicate that a fixed page has been crossed when scrolling in a DataWindow with group headers.
Applies to  | DataWindow control
Syntax  | PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HideGrayLine
```

DataWindow Reference  | 281
**HideSnaked**

Describe and Modify argument:

```
"DataWindow.HideGrayLine { = 'value' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| value      | (exp) Whether a gray line displays in the Preview view and at runtime.  
            | Values are:  
            | Yes – The gray line is hidden.  
            | No – The gray line displays (default).  
            | Value can be a quoted DataWindow expression. |

Usage

This property can be set in the open event for the window in which the DataWindow displays. Note that you cannot suppress the display of repeating group headers.

**In the painter**  Select the DataWindow object by deselecting all controls; then set the value in the Properties view, General tab. This option is enabled only for DataWindows with group headers.

Examples

```
dw1.Object.DataWindow.HideGrayLine = yes
```

---

**HideSnaked**

Description  Whether the control appears only once per page when you print the DataWindow using the newspaper columns format.

Applies to  Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

Syntax  PowerBuilder dot notation:

```
dw_control.Object.controlname.HideSnaked
```

Describe and Modify argument:

```
"controlname.HideSnaked { = 'value' }"
```
**CHAPTER 3  DataWindow Object Properties**

### Horizontal_Spread

**Description**
The space between columns in the detail area of the DataWindow object.

**Applies to**
Style keywords

**Syntax**

```
SyntaxFromSql:

    Style ( Horizontal_Spread = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the space between columns in the detail area of the DataWindow object area in the units specified for the DataWindow</td>
</tr>
</tbody>
</table>

**Examples**

```
SQLCA.SyntaxFromSQL(sqlstring, &
    'Style(...Horizontal_Spread = 25 ...)', errstring)
```
**HorizontalScrollMaximum**

**Description**
The maximum width of the scroll box of the DataWindow’s horizontal scroll bar. This value is set by PowerBuilder based on the layout of the DataWindow object and the size of the DataWindow control. Use HorizontalScrollMaximum with HorizontalScrollPosition to synchronize horizontal scrolling in multiple DataWindow objects.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HorizontalScrollMaximum
```

Describe argument:

```
"DataWindow.HorizontalScrollMaximum"
```

**Examples**

```
string setting
setting = dw1.Object.DataWindow.HorizontalScrollMaximum
setting = dw1.Describe("DataWindow.HorizontalScrollMaximum")
```

---

**HorizontalScrollMaximum2**

**Description**
The maximum width of the second scroll box when the horizontal scroll bar is split (HorizontalScrollSplit is greater than 0). This value is set by PowerBuilder based on the content of the DataWindow. Use HorizontalScrollMaximum2 with HorizontalScrollPosition2 to synchronize horizontal scrolling in multiple DataWindow objects.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HorizontalScrollMaximum2
```

Describe argument:

```
"DataWindow.HorizontalScrollMaximum2"
```

**Examples**

```
string setting
setting = dw1.Object.DataWindow.HorizontalScrollMaximum2
setting = dw1.Describe("DataWindow.HorizontalScrollMaximum2")
```
**HorizontalScrollPosition**

**Description**
The position of the scroll box in the horizontal scroll bar. Use HorizontalScrollMaximum with HorizontalScrollPosition to synchronize horizontal scrolling in multiple DataWindow objects.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HorizontalScrollPosition
```

**Describe and Modify argument:**

```
"DataWindow.HorizontalScrollPosition { = scrollvalue }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scrollvalue</td>
<td>An integer specifying the position of the scroll box in the horizontal scroll bar of the DataWindow</td>
</tr>
</tbody>
</table>

**Examples**

```java
string spos1
spos1 = dw1.Object.DataWindow.HorizontalScrollPosition

string smax1, smax2, spos1, modstring
integer pos2
smax1 = dw1.Describe( & "DataWindow.HorizontalScrollMaximum")
spos1 = dw1.Describe( & "DataWindow.HorizontalScrollPosition")
smax2 = dw_2.Describe( & "DataWindow.HorizontalScrollMaximum")
pos2 = Integer(spos1) * Integer(smax2) / Integer(smax1)
modstring = "DataWindow.HorizontalScrollPosition=" & + String(pos2)
dw1.Modify(modstring)
```

**HorizontalScrollPosition2**

**Description**
The position of the scroll box in the second portion of the horizontal scroll bar when the scroll bar is split (HorizontalScrollSplit is greater than 0). Use HorizontalScrollMaximum2 with HorizontalScrollPosition2 to synchronize horizontal scrolling in multiple DataWindow objects.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HorizontalScrollPosition2
```
**HorizontalScrollSplit**

Describe and Modify argument:

"DataWindow.HorizontalScrollPosition2 { = scrollvalue }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scrollvalue</td>
<td>An integer specifying the position of the scroll box in the second portion of a split horizontal scroll bar of the DataWindow</td>
</tr>
</tbody>
</table>

Examples

```powershell
spos = dw1.Describe( &
    "DataWindow.HorizontalScrollPosition2")
dw1.Modify( &
    "DataWindow.HorizontalScrollPosition2=200")
```

**HorizontalScrollSplit**

Description

The position of the split in the DataWindow’s horizontal scroll bar. If HorizontalScrollSplit is zero, the scroll bar is not split.

Applies to

DataWindows

Syntax

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HorizontalScrollSplit
```

Describe and Modify argument:

"DataWindow.HorizontalScrollSplit { = splitdistance }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>splitdistance</td>
<td>An integer indicating where the split will occur in the horizontal scroll bar in a DataWindow object in the unit of measure specified for the DataWindow object</td>
</tr>
</tbody>
</table>

Examples

```powershell
setting = dw1.Object.DataWindow.HorizontalScrollSplit
dw1.Object.DataWindow.HorizontalScrollSplit = 250
str = dw1.Describe("DataWindow.HorizontalScrollSplit")
dw1.Modify("DataWindow.HorizontalScrollSplit=250")
```
**HTextAlign**

**Description**  
The way text in a button is horizontally aligned.

**Applies to**  
Button controls

**Syntax**  
PowerBuilder dot notation:

```
   dw_control.Object.buttonname.HTextAlign
```

**Describe and Modify argument:**

```
   "buttonname.HTextAlign { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>buttonname</code></td>
<td>The name of the button for which you want to align text.</td>
</tr>
</tbody>
</table>
| `value` | An integer indicating how the button text is horizontally aligned.  
Values are:  
  0 – Center  
  1 – Left  
  2 – Right |

**Usage**  
**In the painter**  
Select the control and set the value in the Properties view, General tab, Horizontal Alignment option.

**Examples**

```
   dw1.Object.b_name.HTextAlign = "1"
   setting = dw1.Describe("b_name.HTextAlign")
   dw1.Modify("b_name.HTextAlign = '1'")
```

**HTML_property**

**Description**  
Settings for adding user-defined HTML syntax and hyperlinks to controls in a Web DataWindow.

**Applies to**  
Column, Computed Field, Picture, and Text controls

**Syntax**  
PowerBuilder dot notation:

```
   dw_control.Object.controlname.HTML_property
```

**Describe and Modify argument:**

```
   "controlname.HTML_property { = 'value' }"
```
### HTML.property

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control whose HTML properties you want to get or set.</td>
</tr>
<tr>
<td>property</td>
<td>A property for generating HTML syntax and hyperlinks in a Web DataWindow. Properties and their values are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. Value can be a quoted DataWindow expression only where noted.</td>
</tr>
</tbody>
</table>

#### Property for HTML

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AppendedHTML</td>
<td>HTML you want to append to the generated syntax for the rendering of a DataWindow control before the closing bracket of the HTML element for that control.</td>
</tr>
<tr>
<td>Link</td>
<td><em>(exp)</em> A URL that is the target of a link (HTML anchor element) generated for each data item in the column or for the specified control. The text or user-visible part of the link will be the data value in the column, the value of the computed field, the text in the Text control, or the image of a Picture control. The URL can include parameters. Other properties, such as LinkArgs, can cause additional parameters to be added when the HTML is generated.</td>
</tr>
</tbody>
</table>
| LinkArgs | A string in the form:  

```
argname='exp' [ | argname = 'exp' ] ...  
```

*Argname* is a page parameter to be passed to the server.  
*Exp* is a DataWindow expression whose value is a string. It is evaluated and converted using URL encoding and included in the *linkargs* string.  
The evaluated LinkArgs string is appended to the HTML.Link property when HTML is generated to produce a hyperlink for each data item in a column or other DataWindow control. |
| LinkTarget | *(exp)* The name of a target frame or window for the hyperlink (HTML A element) specified in the Link property. The target is included using the TARGET attribute.  
You can use the LinkTarget property to direct the new page to a detail window or frame in a master/detail page design.  
If LinkTarget is null or an empty string (""), then no TARGET attribute is generated. |
| ValueIsHTML (does not apply to Picture controls) | *(exp)* A boolean that, if true, allows the control contents (data value in a read-only column, the value of a computed field that is not calculated on the client, or the text in a Text control) to be generated as HTML. For XHTML, the control contents must be well-formed XHTML. |
CHAPTER 3      DataWindow Object Properties

Usage

The Link properties are typically used to create master/detail Web pages where a link on a data item jumps to a detail DataWindow for that item. LinkArgs is used to pass a retrieval argument identifying the particular item.

The AppendedHTML property is used to specify attributes and event actions to add to the HTML rendered for Web DataWindow controls.

ScrollToRow emulation

The ValueIsHTML property allows you to include standalone HTML syntax or tags in the generated Web DataWindow. You can use this feature to add horizontal rules (HR) and anchor tags (A HREF="home.htm">home</A>) to Web DataWindows. If you add row-specific anchor tags, you can use the Modify method or DataWindow expressions to generate conditional HTML for each row.

The HTML generator does not validate the HTML you append to or include in controls in DataWindow objects. If the HTML is invalid, the DataWindow might not display correctly. You must also be careful not to append an event name that is already generated for the control as a coded client-side event.

In the painter

Select the control and set the value in the Properties view, HTML tab.

Examples

// EMPID and PAGE are page parameters for the // page server's session object
dw1.Object.empid.HTML.Link = "empform.html"
dw1.Object.empid.HTML.LinkArgs = "EMPID = 'empid'"
dw1.Object.empid.HTML.LinkTarget = "detail_win"
dw1.Object.empid.HTML.ValueIsHTML = "true"
dw1.Object.helpicon.HTML.Link = "help.html"
dw1.Object.helpicon.LinkArgs = "PAGE = 'empform'"

setting = dw1.Describe("DataWindow.HTML.Link")
dw1.Modify("empid.HTML.Link = 'empform.html'")

HTMLDW

Description

Specifies whether HTML generated for the DataWindow object provides updates and interactivity.

Applies to

DataWindow objects

Syntax

PowerBuilder dot notation:

dw_control/Object/DataWindow.HTMLDW = value
Describe and Modify argument:

"DataWindow.HTMLDW { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value to be assigned to the property. Value can be a quoted DataWindow expression. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Yes – DataWindow HTML generation uses the HTMLGen properties.</td>
</tr>
<tr>
<td></td>
<td>• No – DataWindow HTML generation is a read-only. table as described for the Data.HTMLTable property.</td>
</tr>
</tbody>
</table>

Usage

When HTMLDW is set to Yes, the generated HTML supports data entry and takes advantage of browser features that enable user interaction when used with a page server (as described for the Data.HTML property). The generated HTML can be used to produce a page that displays a subset of retrieved rows and can include JavaScript code requesting additional pages with other subsets of the retrieved rows.

The resulting HTML can be used as a Web DataWindow control, which is a cooperation between a server component, a page server, and a client Web browser. The server component produces the HTML and the page server incorporates it into a Web page.

**HTMLDW set to Yes**

The HTMLDW property is set to Yes automatically when you create an instance of the generic Web DataWindow server component (DataWindow/HTMLGenerator115 for EAServer). In this case, you do not need to set this property in the DataWindow painter or in a script.

The user interacts with the DataWindow in the client browser, and actions produced by buttons in the DataWindow object are sent back to the page server. The page server calls methods of the server component to request processing for the data in the DataWindow object, including applying actions, updating data, and scrolling to other subsets.

For more information, see the DataWindow Programmers Guide. To affect the level of DataWindow features in the resulting HTML, or to produce master/detail links between two Web DataWindow controls, see HTMLGen.property.
DataWindow features that will not be rendered into HTML include:

- Graph, OLE, and RichText presentation styles and controls.
- Client-side expressions that include aggregate functions. Aggregate functions cannot be evaluated in the browser. Instead, they will be evaluated on the server and the resulting value included in the HTML.
- Resizable and movable controls.
- Sliding of controls to fill empty space.
- Autosizing of height or width.
- EditMasks for column data entry.

**In the painter** Select the DataWindow object by deselecting all controls; then select or clear the Web DataWindow check box on the General tab in the Properties view.

**Examples**

```
dw1.Object.DataWindow.HTMLDW = "yes"
```

```
setting = dw1.Describe
        ("DataWindow.HTMLDW")

dw1.Modify("DataWindow.HTMLDW = 'yes'")
```

---

### HTMLGen.property

**Description**
Settings that control the level of features incorporated into HTML generated for the DataWindow.

**Applies to**
DataWindow objects

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HTMLGen.property
```

**Describe** and **Modify** argument:

```
"DataWindow.HTMLGen.property { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property that controls how HTML is generated for a DataWindow. Properties and their values are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. Value can be a quoted DataWindow expression where noted.</td>
</tr>
</tbody>
</table>
**HTMLGen**.property

<table>
<thead>
<tr>
<th>Property for HTMLGen</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Browser</strong></td>
<td><em>(exp)</em> A string identifying the browser in which you want to display the generated HTML. The value should match the browser identifier part of the text string that the browser specifies in the HTTP header it sends to the server. This property is usually set dynamically on the server according to the HTTP header returned from the client. Recognized strings are listed in “Browser recognition” on page 296.</td>
</tr>
</tbody>
</table>
| **ClientComputedFields** | *(exp)* Whether computed fields that reference column data are translated into JavaScript and computed in the client browser. Values are:  
  - Yes – (Default) Computed fields are translated to JavaScript where possible.  
  - No – Computed fields are always calculated on the server. Regardless of this setting, if the computed field includes aggregation functions, the computed field is calculated on the server. For more information about this and the following properties, see “Client properties” on page 296 |
| **ClientEvents**     | *(exp)* Whether JavaScript code to trigger events is included in the generated HTML. Values are:  
  - Yes – (Default) JavaScript for triggering events is generated.  
  - No – JavaScript for events is not generated. |
| **ClientFormatting** | *(exp)* Whether display formats are applied to data items that do not have focus. JavaScript for formatting the data is translated from display formats specified in the DataWindow painter. If you want to use regional settings, such as a period as a date separator and a comma as a decimal separator, you must set ClientFormatting to Yes. Values are:  
  - Yes – (Default) Display formats are applied to data.  
  - No – Display formats are not used. |
| **ClientScriptable** | *(exp)* Whether client-side JavaScript can interact with the control. Values are:  
  - Yes – Client-side JavaScript can call methods of the control.  
  - No – (Default) Client-side JavaScript cannot call methods. This option adds approximately 20K to the size of the generated HTML. |
| **ClientValidation** | *(exp)* Whether JavaScript code to perform validation of user-entered data is included in the generated HTML. The validation code is translated from validation expressions specified in the DataWindow painter. Values are:  
  - Yes – (Default) Validation expressions are generated.  
  - No – Validation expressions are not generated. |
### CommonJSFile

*exp* Cache file name for common JavaScript functions required by Web DataWindows at runtime. If you set this property, the file is downloaded to the browser client once per session for use by all Web DataWindows. You can prefix the file name to a URL, or you can use the URL that you set with the HTMLGen.ResourceBase property. See “JavaScript caching” on page 297.

### DateJSFile

*exp* Cache file name for common Web DataWindow functions that use a date format. If you set this property, the file is downloaded to the browser client once per session for use by all Web DataWindows. You can prefix the file name with a URL, or you can use the URL that you set with the HTMLGen.ResourceBase property. See “JavaScript caching” on page 297.

### EncodeSelfLinkArgs

*exp* A switch to disable HTML 4 encoding of the evaluated HTMLGen.SelfLinkArgs expressions that are generated as hidden fields. The standard encoding limits character replacement to "", ", <, and >. Disabling the standard encoding allows you to encode additional characters, but you must encode the argument expressions yourself.

**Values are:**
- Yes – (Default) Encoding performed by PowerBuilder.
- No – Encoding not performed.

### GenerateDDDWFrames

*exp* Specifies whether drop-down DataWindows are generated using inline frames (iFrames). The use of iFrames enhances the display so that the drop-down DataWindow displays in a Web application as it would in a Windows application. Using iFrames increases the volume of markup generated.

**Values are:**
- Yes – (Default) Drop-down DataWindows are generated in formatted div elements over an iFrame.
- No – Drop-down DataWindows are generated in HTML select elements.

The use of the GenerateDDDWFrames option for drop-down DataWindows is supported only in the Internet Explorer browser. In other browsers, the HTML select element is always used.

### GenerateJavaScript

*exp* Specifies whether to generate JavaScript if the browser is not recognized. Keep in mind that without JavaScript, updating of data is not available. Navigation links are still supported.

**Values are:**
- Yes – (Default) JavaScript is generated even if the browser is not recognized. The resulting JavaScript is portable and does not use browser-specific features.
- No – JavaScript is not generated unless the browser is recognized.
### Property for HTMLGen Value

<table>
<thead>
<tr>
<th>Property for HTMLGen</th>
<th>Value</th>
</tr>
</thead>
</table>
| **HTMLVersion**     | *(exp)* The version of HTML to generate.  
Values are:  
• 3.2 – (Default) The HTML will include style sheets, but no absolute positioning or regular expressions.  
• 4.0 – The HTML will include style sheets, absolute positioning, and regular expressions.  
If the browser is recognized, this property is ignored and browser-specific HTML is generated. |
| **NetscapeLayers**   | *(exp)* Formats the Web DataWindow for Netscape 4.0 or later using absolute positioning (in a manner similar to the formatting for Internet Explorer). See “NetscapeLayers property” on page 298. |
| **NumberJSFile**     | *(exp)* Cache file name for common Web DataWindow functions that use a number format. If you set this property, the file is downloaded to the browser client once per session for use by all Web DataWindows. You can prefix the file name with a URL, or you can use the URL that you set with the HTMLGen.ResourceBase property. See “JavaScript caching” on page 297. |
| **ObjectName**       | *(exp)* A string specifying a name used in generated code for the Web DataWindow client control, page parameters, and client-side events.  
You must specify a unique object name when there will be more than one Web DataWindow on a Web page so that names will not conflict. |
| **PageSize**         | *(exp)* The number of rows of data to include in a generated Web page. If the Web page does not include all available rows, you can include button controls to navigate to the rest of the data. To include all available rows in the page, specify 0 for PageSize.  
If the HTMLDW property is set to Yes, PageSize is used.  
If it is set to No, PageSize is ignored and all rows in the result set are generated in a single page. |
| **PagingMethod**     | A value of the WebPagingMethod enumerated variable that determines how paging is handled.  
Values are:  
  - PostBack! (0) – (default) The control posts back to the server to perform paging operations.  
  - Callback! (1) – The control calls a service on the client to perform paging operations.  
  - XMLClientSide! (2) – The control retrieves the entire XML result set and performs paging operations on the client. This option is only available when the XML rendering format is used.  
See “PagingMethod” on page 297. |
| **ResourceBase**     | *(exp)* The URL for included JavaScript files. If you set this property, you do not need to include a URL in the values for these other HTMLGen properties: CommonJSFile, DateJSFile, NumberJSFile, and StringJSFile. |
## Property for HTMLGen | Value
--- | ---
SelfLink | *(exp)* A string specifying the URL for the current page. It cannot include parameters. Parameters specified in SelfLinkArgs can be added when HTML is generated. SelfLink is used to generate URLs for navigation buttons that obtain additional rows from the result set and for other buttons that reload the page, such as Update and Retrieve.

SelfLinkArgs | A string in the form:

\[
argname='exp1' | argname='exp2' \ldots
\]

*Argname* is a page parameter to be passed to the server.

*Exp* is a DataWindow expression whose value is a string. The DataWindow in the server component evaluates it, converts it using URL encoding, and includes it in the SelfLinkArgs string.

The evaluated SelfLinkArgs expressions are included in the generated HTML as hidden fields. The arguments supply information that the server needs to render additional pages of the result set, such as retrieval arguments.

StringJSFile | *(exp)* Cache file name for common Web DataWindow functions that use a string format. If you set this property, the file is downloaded to the browser client once per session for use by all Web DataWindows. You can prefix the file name with a URL, or you can use the URL that you set with the HTMLGen.ResourceBase property. See “JavaScript caching” on page 297.

TabIndexBase | *(exp)* Sets the starting tab order number for a Web DataWindow. This property is useful for a Web page with multiple Web DataWindows when you can tab between columns of the DataWindows. Setting this property has no effect on page functionality when the page is viewed in a browser that does not support the tab index attribute. The maximum tab index allowed for a page is 32767. See “TabIndexBase property” on page 298.

UserJSFile | *(exp)* Cache file name for user-defined Web DataWindow functions. If you set this property, the file is downloaded to the browser client once per session for use by all Web DataWindows. You can prefix the file name to a URL, or you can use the URL that you set with the HTMLGen.ResourceBase property. See “JavaScript caching” on page 297.

Usage | Most of these properties are considered only when the HTMLDW property is set to Yes.

### HTMLDW set to Yes
The HTMLDW property is set to Yes automatically when you create an instance of the generic Web DataWindow server component (DataWindow/HTMLGenerator115 for EAServer. In this case, you do not need to set this property in the DataWindow painter or in a script.
Browser recognition  The Browser and HTMLVersion properties are always considered when HTML is generated, regardless of the HTMLDW setting.

Browser identification strings are sent by the client to the server in the HTTP header. The server component can assign the HTTP_USER_AGENT value from the HTTP header to the Browser property. If the string specifies a browser that the DataWindow engine supports, the DataWindow will generate HTML optimized for that browser. Browser-specific HTML is generated only for Microsoft Internet Explorer and Netscape browsers.

If the browser is not recognized or not specified, then the generated HTML will use the HTMLVersion and GenerateJavaScript properties to decide what features to include. DataWindow HTML generation recognizes these browsers:

<table>
<thead>
<tr>
<th>Browser</th>
<th>HTTP header string</th>
<th>HTML features used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Netscape</td>
<td>Mozilla/1.x</td>
<td>No style sheets, no absolute positioning, no JavaScript.</td>
</tr>
<tr>
<td></td>
<td>Mozilla/2.x</td>
<td>JavaScript.</td>
</tr>
<tr>
<td></td>
<td>Mozilla/3.x</td>
<td>No style sheets, no absolute positioning, no regular expressions.</td>
</tr>
<tr>
<td></td>
<td>Mozilla/4.x</td>
<td>Style sheets, JavaScript, regular expressions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No absolute positioning.</td>
</tr>
<tr>
<td>Microsoft Internet Explorer</td>
<td>Mozilla/1.22 (compatible; MSIE 2.x)</td>
<td>No style sheets, no absolute positioning, no tab order, no JavaScript.</td>
</tr>
<tr>
<td></td>
<td>Mozilla/2.0 (compatible; MSIE 3.x)</td>
<td>Style sheets, tab order, JavaScript.</td>
</tr>
<tr>
<td></td>
<td>Mozilla/4.0 (compatible; MSIE 4.x, 5.x, 6.x)</td>
<td>Style sheets, absolute positioning, tab order, regular expressions.</td>
</tr>
<tr>
<td>Opera</td>
<td>Mozilla/3.0 (compatible; Opera 3.x)</td>
<td>JavaScript, regular expressions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No style sheets, no absolute positioning.</td>
</tr>
</tbody>
</table>

Client properties  The ClientEvents, ClientFormatting, ClientValidation, ClientComputedFields, and ClientScriptable properties control the amount of JavaScript that is generated for the Web DataWindow, which impacts the size of the page that is downloaded to the browser. You can reduce the size of the generated HTML by setting one or more of the properties to No.
JavaScript caching  You can also reduce the size of the generated HTML by setting up cache files for common Web DataWindow client-side methods. You can generate these files using the JavaScript Generation wizard that you launch from a button on the JavaScript Generation tab of the Properties view in the DataWindow painter.

Once you generate these files, you can set the file names as values for the CommonJSFile, DateJSFile, NumberJSFile, and/or StringJSFile properties. When you set these properties, the methods defined in the referenced files will not be generated with the HTML in any Web DataWindow pages that are sent to the page server and client browser.

With JavaScript caching, you improve performance after the first Web DataWindow page is generated—as long as the browser on the client computer is configured to use cached files. With caching enabled, the browser loads the JS files from the Web server into its cache, and these become available for all the Web DataWindow pages in your application. There is no performance gain if the browser does not find the JS files in its cache since, in this case, it reloads the files from the Web server.

PagingMethod  The PagingMethod property determines whether the control uses the client-side script callback mechanism introduced in the .NET Framework 2.0 to execute server-side code without posting and refreshing the current page.

The default is to post back to the server (PostBack!).

The Callback! option uses script callbacks to retrieve the next page of XML data. It corresponds to the Microsoft GridView control’s EnableSortingAndPagingCallback property, but applies only to paging. Client-side sorting is handled by another mechanism.

For the XML rendering format, the design of the Callback! option requires that a reusable XSLT stylesheet be generated so that the browser can cache it. The benefit from this requirement is that only the XML data for the next requested page need be returned by the callback. This XML data is always trivial in size (about a 1 to 20 ratio), resulting in significant bandwidth savings. This is unlike other implementations, where the entire presentation is always regenerated and downloaded again from every callback.

The generated XSLT stylesheet is not reusable, and therefore cannot be cached by the browser, if the DataWindow layout is inconsistent page-to-page, or it does not contain a complete first page of data. In these scenarios, the Callback! option defers to PostBack! until a stylesheet can be generated that is reusable, and can therefore be cached in the browser.
The XMLClientSide! option is only available with the XML rendering format. It retrieves the entire XML result set and uses XSLT re-transformation of the cached stylesheet to perform paging on the client. This option can currently be used only if the presentation style is uniform from page to page. For example, it cannot handle a summary band on the last page.

When PagingMethod is set to XMLClientSide!, InsertRow, AppendRow, and DeleteRow actions do not require a postback or callback to the server. However, computed fields in the DataWindow that are dependent on the RowCount method are not refreshed until an action such as Update or Retrieve forces a postback to the server.

**NetscapeLayers property** Even if you set the NetscapeLayers property to true, certain functionality in a Netscape browser using absolute positioning might not be identical to the functionality available with Internet Explorer. For example, you cannot tab between DataWindow columns using a Netscape browser on an NT machine (although you can do this using a Netscape browser on a Solaris machine).

**TabIndexBase property** If you add Web DataWindows to a page that already has a Web DataWindow on it, you can set the TabIndexBase property for each Web DataWindow you add.

For a page with two Web DataWindows, setting the tab index base for the second DataWindow to a number greater than the tab index for the last column of the first DataWindow allows the user (using an Internet Explorer browser) to tab through all the columns of the first DataWindow before tabbing to the second DataWindow. Otherwise, pressing the Tab key could cause the cursor and focus to jump from one DataWindow to another instead of tabbing to the next column in the DataWindow that initially had focus.

**In the painter** Select the DataWindow object by deselecting all controls; then set the values in the Properties view, Web Generation tab or JavaScript Generation tab. Select HTML/XHTML from the Format to Configure list to display the properties.

```
Examples

dw1.Object.DataWindow.HTMLGen.HTMLVersion = "4.0"
setting = dw1.Describe
("DataWindow.HTMLGen.Browser")
dw1.Modify("DataWindow.HTMLGen.ClientValidation = 'no'")
dw1.Modify("DataWindow.HTMLGen.PublishPath= 'C:\Inetpub\wwwroot\MyWebApp\generatedfiles'")
dw1.Modify("DataWindow.HTMLGen.ResourceBase= '/MyWebApp/generatedfiles'")
```

PowerBuilder
This statement sets the XMLGen.Paging property so that the complete result set is downloaded to the client and paging takes place on the client:

```
dw1.Modify("DataWindow.HTMLGen.PagingMethod=XMLClientSide!")
```

This statement sets the HTMLGen.PagingMethod property to use script callbacks:

```
dw1.Object.DataWindow.HTMLGen.PagingMethod=1
```

**HTMLTable.property**

Description: Settings for the display of DataWindow data when displayed in HTML table format. These settings simplify the transfer of data from a database to an HTML page. They are particularly useful when used to create HTML pages dynamically.

Applies to: DataWindow objects

Syntax: PowerBuilder dot notation:

```
dw_control.Object.DataWindow.HTMLTable.property
```

Describe and Modify argument:

```
"DataWindow.HTMLTable.property { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for a DataWindow to be displayed in HTML table format. Properties and their values are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for HTMLTable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Border</td>
<td>(exp) Border attribute for the HTMLTable element. The default is 1 (line around the table).</td>
</tr>
<tr>
<td>CellPadding</td>
<td>(exp) CellPadding attribute for the HTMLTable element. The default is 0.</td>
</tr>
<tr>
<td>CellSpacing</td>
<td>(exp) CellSpacing attribute for the HTMLTable element. The default is 0.</td>
</tr>
<tr>
<td>GenerateCSS</td>
<td>(exp) Controls whether the DataWindow HTMLTable property’s Table element contains border, cellpadding, cellspacing, nowrap, and width attributes. Also controls whether elements within the table contain CLASS references that control style sheet use. The default is no.</td>
</tr>
<tr>
<td>NoWrap</td>
<td>(exp) NoWrap attribute for the HTMLTable element. The default is to include this attribute.</td>
</tr>
</tbody>
</table>
### ID

**Description**
The number of the column or TableBlob.

**Applies to**
Column and TableBlob controls

**Syntax**
PowerBuilder dot notation:

```powerbuilder
dw_control/Object/controlname.ID
```

**Describe and Modify argument:**

```
"controlname.ID"
```

**Examples**

```powerbuilder
setting = dw1.Object.empname.ID
setting = dw1.Describe("empname.ID")
```

### Identity

**Description**
Whether the database is to supply the value of the column in a newly inserted row. If so, the column is not updatable; the column is excluded from the INSERT statement.

Not all DBMSs support the identity property. For more information see the documentation for your DBMS.

**Applies to**
Column controls

---

**Property for HTMLTable**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StyleSheet</td>
<td><em>(exp)</em> HTML cascading style sheet generated for the DataWindow.</td>
</tr>
<tr>
<td>Width</td>
<td>Width attribute for the HTMLTable element. The default is 0.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**
Set the value using the Properties view, HTML Table tab.

**Examples**

```powerbuilder
dw1.Object.DataWindow.HTMLTable.Border = "2"

setting = dw1.Describe
("DataWindow.HTMLTable.StyleSheet")

dw1.Modify("DataWindow.HTMLTable.NoWrap = 'yes'")
```
CHAPTER 3  DataWindow Object Properties

Syntax

PowerBuilder dot notation:

\[
\text{dw\_control}\cdot\text{Object}\cdot\text{columnname}\cdot\text{Identity}
\]

Describe and Modify argument:

\["\text{columnname}\cdot\text{Identity} \{= \text{value}\}\"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>A string containing the name of the column for which you want to get or set the identity property.</td>
</tr>
<tr>
<td>value</td>
<td>A string indicating whether a column’s value in a newly inserted row is supplied by the DBMS: Yes – The DBMS will supply the value of the column in a newly inserted row; the column is not updatable. No – The column is updatable.</td>
</tr>
</tbody>
</table>

Examples

dw1\cdot\text{Object}\cdot\text{empid}\cdot\text{Identity} = "yes"
dw1\cdot\text{Modify}("\text{empid}\cdot\text{Identity}='yes'")

Import.XML.Trace

Description

Setting that determines whether import trace information is written to a log file.

Applies to

DataWindow objects

Syntax

PowerBuilder dot notation:

\[
\text{dw\_control}\cdot\text{Object}\cdot\text{DataWindow}\cdot\text{Import.XML}\cdot\text{Trace}
\]

Describe and Modify argument:

\["\text{DataWindow}\cdot\text{Import.XML}\cdot\text{Trace} \{= \text{value}\}\"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether trace information is written to a log file. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Yes – Trace information is written to a log file.</td>
</tr>
<tr>
<td></td>
<td>• No – Trace information is not written to a log file (default).</td>
</tr>
</tbody>
</table>

Usage

If you want to collect trace information, this property should be set before you call the ImportClipboard, ImportFile, or ImportString method to import data from an XML document. The trace information is appended to the file you specify using the Import.XML.TraceFile property. If no trace file is specified, trace information is appended to a file named \text{pbxmltrc.log} in the current directory.
Import.XML.TraceFile

**In the painter**  In the Data Import tab in the Properties view for the DataWindow object, select XML from the Format to Configure list, and type a file name in the Trace File Name text box.

**Examples**  This example specifies that trace information should be written to a file called xmltrace.log in the C:\temp directory.

```powerbuilder
    dw1.Modify("DataWindow.Import.XML.Trace = 'yes' ")
    dw1.Modify("DataWindow.Import.XML.TraceFile = 'C:\temp\xmltrace.log' ")
```

**See also**  Import.XML.TraceFile

---

Import.XML.TraceFile

**Description**  Specifies the name and location of an import trace file.

**Applies to**  PowerBuilder dot notation:

```powerbuilder
    dw_control.Object.DataWindow.Import.XML.TraceFile
```

**Syntax**  Describe and Modify argument:

```powerbuilder
    "DataWindow.Import.XML.TraceFile { = 'value'}"
```

**Parameter Description**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>A string whose value is the name of the trace output file. If the file does not exist, it is created.</td>
</tr>
</tbody>
</table>

**Usage**  If you want to collect trace information, the Import.XML.Trace property should be set before you call the ImportClipboard, ImportFile, or ImportString method to import data from an XML document. The trace information is appended to the file you specify using the Import.XML.TraceFile property. If no trace file is specified, trace information is appended to a file named pbxmltrc.log in the current directory.

**In the painter**  In the Data Import tab in the Properties view for the DataWindow object, select XML from the Format to Configure list, and type a file name in the Trace File Name text box.

**Examples**  This example specifies that trace information should be written to a file called xmltrace.log in the C:\temp directory.

```powerbuilder
    dw1.Object.DataWindow.Import.XML.Trace = 'yes'
    dw1.Object.DataWindow.Import.XML.TraceFile = 'C:\temp\xmltrace.log'
```

**See also**  Import.XML.Trace
**Import.XML.UseTemplate**

**Description**
Setting that optionally controls the logical structure of the XML imported from an XML file into a DataWindow object using the ImportFile method.

**Applies to**
DataWindow objects

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Import.XML.UseTemplate
```

Describe and Modify argument:

```
"DataWindow.Import.XML.UseTemplate { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>(exp) A string specifying the name of an import template previously saved in the DataWindow painter for the specified DataWindow object</td>
</tr>
</tbody>
</table>

**Usage**
This property should be set to specify the logical structure of the XML imported before you call the ImportFile method to import data from an XML document. An import template is not required if the XML document from which data is imported corresponds to the DataWindow column definition.

If an export template for a DataWindow object exists, it can be used as an import template. Only the mapping of column names to element attribute names is used for import. The order of elements within the template is not significant, because import values are located by name match and nesting depth within the XML document. All other information in the template, such as controls and comments, is ignored.

**In the painter**
In the Data Import tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select a template from the Use Template list.

**Examples**
This example sets the name of the current XML import template used in dw1 to `t_import_report`. If `t_import_report` does not exist, the current template is not changed.

```
dw1.Modify("DataWindow.Import.XML.UseTemplate = 't_import_report' ")
```

**See also**
Export.XML.UseTemplate
### Initial

**Description**

The initial value of the column in a newly inserted row.

**Applies to**

Column controls

**Syntax**

PowerBuilder dot notation:

\[
\text{dw\_control.Object.columnname.Initial}
\]

**Describe and Modify argument:**

"\text{columnname.Initia}l \{ = \text{initialvalue} \}"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{columnname}</td>
<td>A string containing the name of the column for which you want to get or set the initial property.</td>
</tr>
<tr>
<td>\text{initialvalue}</td>
<td>A string containing the initial value of the column. Special values include: Empty – A string of length 0, Null – No value, Spaces – All blanks, Today – Current date, time, or date and time</td>
</tr>
</tbody>
</table>

**Examples**

```
setting = dw1.Object.empname.Initial
```

```
dw1.Object.empname.Initial = "empty"
```

```
setting = dw1.Describe("empname.Initial")
```

```
dw1.Modify("empname.Initial='empty'")
```

```
dw1.Modify("empstatus.Initial='A'")
```

### Ink.property

**Description**

Properties that control the attributes of ink in an InkPicture control or a column with the InkEdit edit style.

**Applies to**

Column and InkPicture controls

**Syntax**

PowerBuilder dot notation:

\[
\text{dw\_control.Object.inkpicname.Ink.property}
\]

\[
\text{dw\_control.Object.columnname.Ink.property}
\]

**Describe and Modify argument:**

"\text{inkpicname.Ink.property} \{ = \text{value} \}"

"\text{columnname.Ink.property} \{ = \text{value} \}"

---

304 PowerBuilder
# CHAPTER 3   DataWindow Object Properties

## Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inkpicname</td>
<td>The name of an InkPicture control.</td>
</tr>
<tr>
<td>columnname</td>
<td>The name of a column that has the InkEdit edit style.</td>
</tr>
<tr>
<td>property</td>
<td>A property for the InkPicture control or InkEdit column. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property.</td>
</tr>
</tbody>
</table>

## Property for Ink

<table>
<thead>
<tr>
<th>Property for Ink</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AntiAliased</td>
<td>A drawing attribute that specifies whether the foreground and background colors along the edge of the drawn ink are blended (antialiased) to make the stroke smoother and sharper. Values are: true – The ink stroke appears smoother and sharper (default) false – The ink stroke is not antialiased Painter: InkAntiAliased option.</td>
</tr>
<tr>
<td>Color</td>
<td>A drawing attribute that specifies the current ink color. The default color is black. Painter: InkColor option.</td>
</tr>
<tr>
<td>Height</td>
<td>A drawing attribute that specifies the height of the side of the rectangular pen tip in HIMETRIC units (1 HIMETRIC unit = .01mm). The default is 1. Painter: InkHeight option.</td>
</tr>
<tr>
<td>IgnorePressure</td>
<td>A drawing attribute that specifies whether the drawn ink gets wider as the pressure of the pen tip on the tablet surface increases. Values are: true – Pressure from the pen tip is ignored false – The width of the ink increases with the pressure of the pen tip (default) Painter: IgnorePressure option.</td>
</tr>
<tr>
<td>Pentip</td>
<td>A drawing attribute that specifies whether the pen tip is round or rectangular. Values are: Ball (0) – The pen tip is round (default) Rectangle (1) – The pen tip is rectangular Painter: PenTip option.</td>
</tr>
<tr>
<td>Transparency</td>
<td>A drawing attribute that specifies the transparency of drawn ink. The range of values is from 0 for totally opaque (the default) to 255 for totally transparent. Painter: InkTransparency option.</td>
</tr>
<tr>
<td>Width</td>
<td>A drawing attribute that specifies the width of the side of the rectangular pen tip in HIMETRIC units (1 HIMETRIC unit = .01mm). The default is 53. Painter: InkWidth option.</td>
</tr>
</tbody>
</table>
**InkEdit.property**

**Usage**

*In the painter*  
Select the control and set values in the Properties view, Ink or InkPicture tab, InkAttributes section.

**Examples**

```powershell
dw1.Object.inkpic1.Ink.Antialiased = true
li_color = dw1.Describe("emp_status.Ink.Color")
```

**See also**

InkEdit.property  
InkPic.property

---

**InkEdit.property**

**Description**  
Properties that control the behavior of a column with the InkEdit edit style.

**Applies to**  
Column controls

**Syntax**  
PowerBuilder dot notation:

```powershell
dw_control.Object.columnname.InkEdit.property
```

Describe and Modify argument:

```powershell"columnname.InkEdit.property { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The name of a column that has the InkEdit edit style.</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property for the InkEdit column. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to be assigned to the property.</td>
</tr>
</tbody>
</table>

**Property for InkEdit**

<table>
<thead>
<tr>
<th><strong>Value</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AutoSelect</strong></td>
</tr>
<tr>
<td>Whether to select the contents of the edit control automatically when it receives focus. Values are:</td>
</tr>
<tr>
<td>Yes – Select automatically (default).</td>
</tr>
<tr>
<td>No – Do not select automatically.</td>
</tr>
<tr>
<td>You can use AutoSelect with SyntaxFromSql. The setting applies to all the columns in the generated syntax.</td>
</tr>
<tr>
<td>Painter: Auto Selection option.</td>
</tr>
<tr>
<td><strong>DisplayOnly</strong></td>
</tr>
<tr>
<td>Specifies whether the text is display-only and cannot be changed by the user. Values are:</td>
</tr>
<tr>
<td>true – Text cannot be changed by user.</td>
</tr>
<tr>
<td>false – Text can be changed by user (default).</td>
</tr>
<tr>
<td>Painter: Display Only option.</td>
</tr>
</tbody>
</table>
CHAPTER 3  DataWindow Object Properties

<table>
<thead>
<tr>
<th>Property for InkEdit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Factoid</td>
<td>Specifies a context for ink recognition. Set this property if the input data is of a known type, such as a date or Web address, to constrain the search for a recognition result. Possible values include digit, e-mail, Web, date, time, number, currency, percent, and telephone. For a list of values, see the table that follows. Painter: Factoid option.</td>
</tr>
<tr>
<td>FocusRectangle</td>
<td>Whether a dotted rectangle (the focus rectangle) will surround the current row of the column when the column has focus. Values are: Yes – (Default) Display the focus rectangle. No – Do not display the focus rectangle (default). You can use FocusRectangle with SyntaxFromSql. The setting applies to all the columns in the generated syntax. Painter: Show Focus Rectangle option.</td>
</tr>
<tr>
<td>HScrollbar</td>
<td>Whether a horizontal scroll bar displays in the edit control. Values are: Yes – Display the horizontal scroll bar. No – Do not display the horizontal scroll bar (default). Painter: Horizontal Scroll Bar option.</td>
</tr>
<tr>
<td>InkMode</td>
<td>Specifies whether ink collection is enabled and whether ink only or ink and gestures are collected. Values are: InkDisabled (0) – Ink collection is disabled. CollectInkOnly (1) – Only ink is collected. CollectInkAndGestures (2) – Ink and gestures are collected (default). Painter: InkMode option.</td>
</tr>
<tr>
<td>Limit</td>
<td>A number specifying the maximum number of characters (0 to 32,767) that the user can enter. 0 means unlimited. Painter: Limit option.</td>
</tr>
<tr>
<td>NilIsNull</td>
<td>Whether to set the data value of the InkEdit to null when the user leaves the edit box blank. Values are: Yes – Make the Empty string null. No – Do not make the empty string null (default). Painter: Empty String is null option.</td>
</tr>
<tr>
<td>RecognitionTimer</td>
<td>Specifies the time period in milliseconds between the last ink stroke and the start of text recognition. The default is 2000 (two seconds). Painter: RecognitionTimer option.</td>
</tr>
<tr>
<td>Required</td>
<td>Whether the column is required. Values are: Yes – Required. No – (Default) Not required. Painter: Required option.</td>
</tr>
</tbody>
</table>
Usage

The following values for Factoid are available. After the Default and None factoids, the drop-down list in the Properties view displays factoids for special formats in alphabetical order, followed by single-character factoids and Asian-language factoids. You can set multiple factoids by separating them with the pipe ( | ) character.

<table>
<thead>
<tr>
<th>Factoid</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>Returns recognizer to the default setting. For Western languages, the default setting includes the user and system dictionaries, various punctuation marks, and the Web and Number factoids. For Eastern languages, the default setting includes all characters supported by the recognizer.</td>
</tr>
<tr>
<td>None</td>
<td>Disables all factoids, dictionaries, and the language model.</td>
</tr>
<tr>
<td>Currency</td>
<td>Currency in pounds, dollars, euros, and yen.</td>
</tr>
<tr>
<td>Date</td>
<td>Dates written in English; for example 8/19/2005, Aug 19, 2005, or Friday, August 19, 2005.</td>
</tr>
<tr>
<td>E-mail</td>
<td>E-mail addresses.</td>
</tr>
<tr>
<td>Filename</td>
<td>Windows file name paths. The name cannot include the following characters: / : &quot; &lt; &gt;</td>
</tr>
<tr>
<td>Number</td>
<td>Numeric values, including ordinals, decimals, separators, common suffixes, and mathematical symbols. This factoid includes the Currency and Time factoids.</td>
</tr>
<tr>
<td>Percent</td>
<td>A number followed by the percent symbol.</td>
</tr>
<tr>
<td>Postal Code</td>
<td>Postal codes as written in English, for example 01730 or CT17 9PW.</td>
</tr>
<tr>
<td>System Dictionary</td>
<td>Words in the system dictionary only.</td>
</tr>
<tr>
<td>Telephone</td>
<td>Telephone numbers as written in English, for example (555) 555 5555 or +44 1234 123456.</td>
</tr>
<tr>
<td>Time</td>
<td>Times as written in English, for example 15:05 or 3:05 pm.</td>
</tr>
<tr>
<td>Web</td>
<td>Various URL formats.</td>
</tr>
</tbody>
</table>
In addition, the following Asian-language factoids are available:

<table>
<thead>
<tr>
<th>Factoid</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Word List</td>
<td>Words on the word list associated with the recognizer context only.</td>
</tr>
<tr>
<td>Digit</td>
<td>A single digit (0–9).</td>
</tr>
<tr>
<td>One Char</td>
<td>A single ANSI character.</td>
</tr>
<tr>
<td>Upper Char</td>
<td>A single uppercase character.</td>
</tr>
</tbody>
</table>

In the painter  Select the control and set values in the Properties view, Ink tab for properties relating to Ink, or the Edit tab for properties common to other edit styles. The Style Type on the Edit tab must be set to InkEdit.

Examples

```powerbuilder
class string str
dw1.Object.emp_name.InkEdit.Factoid = EMAIL
str = dw1.Describe("emp_bd.InkEdit.Factoid=") + EMAIL
str = dw1.Modify("emp_bd.InkEdit.Factoid=EMAIL")

class string str
dw1.Object.emp_name.InkEdit.AutoHScroll Required = "no"
```

See also  Ink.property

**InkPic.property**  Properties that control the behavior of ink in an InkPicture control.

**Description**  InkPicture controls

**Applies to**  PowerBuilder dot notation:

```
dw_control.Object.inkpicname.InkPic.property
```

**Syntax**  Describe and Modify argument:

```
"inkpicname.InkPic.property { = value }"
```
### Parameter | Description
--- | ---
`inkpicname` | The name of an InkPicture control.
`property` | A property for the InkPicture control. Properties and their settings are listed in the table below.
`value` | The value to be assigned to the property.

### Property for InkPic | Value
--- | ---
**AutoErase** | Specifies whether the auto erase feature available on some styluses is turned on. Values are:
true – AutoErase is turned on.
false – AutoErase is turned off (default).
Painter: AutoErase option.

**BackColor** | Specifies the numeric value of the background color: –2 to 16,777,215. For more information about color, see the RGB function.
Painter: BackColor option.

**CollectionMode** | Specifies whether ink only, gestures only, or ink and gestures are collected. Values are:
InkOnly (0) – Only ink is collected (default).
GestureOnly (1) – Only gestures are collected.
InkAndGesture (2) – Ink and gestures are collected.
Painter: CollectionMode option.

**DynamicRendering** | Specifies whether the ink is rendered (displayed in the control) as it is drawn. The default is true.
Painter: DynamicRendering option.

**EditMode** | Specifies whether the editing mode of the control is set for drawing, deleting, or selecting ink. Values are:
InkMode (0) – Ink is drawn (default).
DeleteMode (1) – Ink is deleted.
SelectMode (2) – Ink is selected.
Painter: EditMode option.

**EraserMode** | Specifies whether ink is removed by stroke or point. Values are:
StrokeErase (0) – The entire ink stroke under the stylus is removed (default).
PointErase (1) – Only the ink under the stylus is removed.
Painter: EraserMode option.

**EraserWidth** | Specifies the width of the eraser pen tip in HIMETRIC units (1 HIMETRIC unit = .01mm). The default is 212. This property applies when EditMode is set to DeleteMode and EraserMode is set to PointErase.
Painter: EraserWidth option.
### DataWindow Object Properties

#### CHAPTER 3

#### DataWindow Reference

---

**Usage**

*In the painter*  
Select the control and set values in the Properties view, InkPicture tab.

**Examples**

```
InkPic.InkEnabled = true
```

```
li_color = dw1.Describe("inkpic1.InkPic.BackColor")
```

**See also**

Ink.property

---

**Invert**

**Description**

The way the colors in a Picture control are displayed, either inverted or normal.

**Applies to**

Picture controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.bitmapname.Invert
```

Describe and Modify argument:

```
"bitmapname.Invert { = 'number' }"
```

---

**Property for InkPic | Value**

<table>
<thead>
<tr>
<th>Property for InkPic</th>
<th>Value</th>
</tr>
</thead>
</table>
| HighContrastInk     | Specifies whether ink is rendered in a single color when the system is in high contrast mode and draws the selection rectangle and handles in high contrast. Values are:  
true – Ink is rendered in a single color in high contrast mode (default).  
false – Ink is not rendered in a single color in high contrast mode.  
Painter: HighContrastInk option. |
| InkEnabled          | Specifies whether the InkPicture control collects pen input. Values are:  
true – The control collects pen input (default).  
false – The control does not collect pen input and no pen-related events fire.  
Painter: InkEnabled option. |
| MarginX             | Specifies the x-axis margin around the control in PowerBuilder units. The default value is 0.  
Painter: MarginX option. |
| MarginY             | Specifies the y-axis margin around the control in PowerBuilder units. The default value is 0.  
Painter: MarginY option. |
| PictureSizeMode     | Specifies how the picture is displayed in the control. Values are:  
Center Image (1) – The picture is centered in the control.  
Normal (2) – The picture is displayed in the upper-left corner of the control and any part of the picture that does not fit in the control is clipped (default).  
Stretch (3) – The picture is stretched to fill the control.  
Painter: PictureSizeMode option. |
JSGen.property

Parameter | Description
---------|----------------------------------
bitmapname | The name of the Picture control in the DataWindow for which you want to invert the colors.

number | *(exp)* A boolean number indicating whether the colors of the picture will display inverted. Values are:
0 – (Default) No; do not invert the picture’s colors.
1 – Yes; display the picture with colors inverted.

Number can be a quoted DataWindow expression.

Usage

**In the painter** Select the control and set the value in the Properties view, General tab, Invert Image check box.

Examples

```
string setting
setting = dw1.Object.bitmap_1.Invert
dw1.Object.bitmap_1.Invert="0-tIf(empstatus='A',0,1)"

setting = dw1.Describe("bitmap_1.Invert")
dw1.Modify( &
"bitmap_1.Invert='0-tIf(empstatus='~A~','0,1')"
)
```

JSGen.property

Description

Settings that specify the physical path to which generated JavaScript is published and the URL indicating the location of the generated JavaScript.

Applies to

DataWindow objects

Syntax

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.JSGen.property
```

Describe and Modify argument:

```
"DataWindow.JSGen.property { = 'value' }"
```

Parameter | Description
---------|----------------------------------
property | One of the following:
• PublishPath
• ResourceBase

value | *(exp)* PublishPath – A string that specifies the physical path of the Web site folder to which PowerBuilder publishes the generated JavaScript.
*(exp)* ResourceBase – A string that specifies the URL of the generated JavaScript for performing client-side XSLT transformation and instantiation of client-side data.
Usage

The PublishPath folder must correspond to the URL specified in the ResourceBase property. At runtime, after PowerBuilder generates JavaScript to the PublishPath folder, it includes it in the final XHTML page by referencing it with the value of the ResourceBase property in a `<script>` element.

**In the painter** In the JavaScript Generation tab in the Properties view for the DataWindow object, select XHTML from the Format to Configure list and specify the ResourceBase and Publish Path locations.

Examples

These statements set the JSGen.ResourceBase and JSGen.PublishPath properties:

```
dw1.Object.DataWindow.JSGen.PublishPath= & 'C:\work\outputfiles\xmlsource'
```

Key

**Description** Whether the column is part of the database table’s primary key.

**Applies to** Column controls

**Syntax** PowerBuilder dot notation:

```
dw_control.Object.columnname.Key
```

Describe and Modify argument:

```
"columnname.Key { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The column for which you want to get or set primary key status.</td>
</tr>
<tr>
<td>value</td>
<td>Whether the column is part of the primary key. Values are: Yes – The column is part of the primary key No – The column is not part of the key</td>
</tr>
</tbody>
</table>

Usage

**In the painter** Set the value using the Rows menu, Update Properties.

Examples

```
string setting
setting = dw1.Object.empid.Key
dw1.Object.empid.Key = "Yes"

setting = dw1.Describe("empid.Key")
dw1.Modify("empid.Key=Yes")
```
KeyClause

Description
An expression to be used as the key clause when retrieving the blob.

Applies to
TableBlob controls

Syntax
PowerBuilder dot notation:
\[ \text{dw_control}.\text{Object}.\text{tblobname}.\text{KeyClause} \]

Describe and Modify argument:
\[ "\text{tblobname}.\text{KeyClause} \{ = 'keyclause' \}" \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tblobname</td>
<td>The name of the TableBlob for which you want to specify a key clause.</td>
</tr>
<tr>
<td>keyclause</td>
<td>(exp) A string that will be built into a key clause using the substitutions provided. The key clause can be any valid WHERE clause. Key clause can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage
In the painter
Select the control and set the value in the Properties view, Definition tab, Key Clause option.

Examples
With the following setting, the value of key_col will be put in col2 when PowerBuilder constructs the WHERE clause for the SELECTBLOB statement:
\[ \text{dw1}.\text{Modify}(\text{blob_1}.\text{KeyClause}= 'Key_col = :col2') \]

Label.property

Description
Settings for a DataWindow whose presentation style is Label.

Applies to
DataWindows

Syntax
PowerBuilder dot notation:
\[ \text{dw_control}.\text{Object}.\text{DataWindow}.\text{Label.property} \]

Describe and Modify argument:
\[ "\text{DataWindow}.\text{Label.property} \{ = value \}" \]

SyntaxFromSql:
\[ \text{DataWindow}(\text{Label.property} = \text{value}) \]
<table>
<thead>
<tr>
<th>Parameter for Label</th>
<th>Property Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for the Label presentation style. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. For Label properties, value cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for Label</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns</td>
<td>An integer indicating the number of columns of labels on a sheet. Painter: Label group, Labels Across option.</td>
</tr>
<tr>
<td>Columns.Spacing</td>
<td>An integer indicating the space between columns of labels in the units specified for the DataWindow object. Painter: Arrangement group, Between Columns option.</td>
</tr>
<tr>
<td>Ellipse_Height</td>
<td>An integer specifying the radius of the vertical part of the label in the unit of measure specified for the DataWindow object. Painter: Not set in painter.</td>
</tr>
<tr>
<td>Ellipse_Width</td>
<td>An integer radius of the horizontal part of the label in the unit of measure specified for the DataWindow object. Painter: Not set in painter.</td>
</tr>
<tr>
<td>Height</td>
<td>An integer specifying the height of a label in the units specified for the DataWindow object. Painter: Label group, Height option.</td>
</tr>
<tr>
<td>Name</td>
<td>A string containing the name of a label. Painter: Predefined Label option.</td>
</tr>
<tr>
<td>Rows</td>
<td>An integer indicating the number of rows of labels on a sheet. Painter: Label group, Labels Down option.</td>
</tr>
<tr>
<td>Rows.Spacing</td>
<td>An integer indicating the space between rows of labels on a sheet in the units specified for the DataWindow object. Painter: Arrangement group, Between Rows option.</td>
</tr>
<tr>
<td>Shape</td>
<td>A string specifying the shape of a label. Values are: Rectangle RoundRectangle Oval Painter: Not set in painter.</td>
</tr>
</tbody>
</table>
**LabelDispAttr.fontproperty**

<table>
<thead>
<tr>
<th>Property for Label</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sheet (Describe only)</td>
<td>Whether the paper is sheet fed or continuous. Values are: Yes – Sheet fed No – Continuous Painter: Arrangement group, Paper option.</td>
</tr>
<tr>
<td>TopDown (Describe only)</td>
<td>Whether the labels will be printed from the top to the bottom or across the page. Values are: No – Print labels across the page. Yes – Print labels from top to bottom. Painter: Arrangement group, Arrange option.</td>
</tr>
<tr>
<td>Width</td>
<td>An integer specifying the width of a label in the units specified for the DataWindow object. Painter: Label group, Width option.</td>
</tr>
</tbody>
</table>

**Usage**

*In the painter*  Select the DataWindow object by deselecting all controls; then set the value in the Properties view, General tab (when presentation style is Label).

**Examples**

```powershell
string setting
setting = dw1.Object.DataWindow.Label.Sheet
dw1.Object.DataWindow.Label.Width = 250

setting = dw1.Describe("DataWindow.Label.Sheet")
dw1.Modify("DataWindow.Label.Width=250")
dw1.Modify("DataWindow.Label.Height=150")
dw1.Modify("DataWindow.Label.Columns=2")
dw1.Modify("DataWindow.Label.Width=250")
dw1.Modify("DataWindow.Label.Name='Address1'")
```

**LabelDispAttr.fontproperty**

See DispAttr.fontproperty.
**LastRowOnPage**

**Description**
The last row currently visible in the DataWindow.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.LastRowOnPage
```

**Describe argument:**

```
"DataWindow.LastRowOnPage"
```

**Examples**

```
string setting
setting = dw1.Object.DataWindow.LastRowOnPage
```

```
setting = dw1.Describe("DataWindow.LastRowOnPage")
```

---

**Left_Margin**

**Description**
The size of the left margin of the DataWindow object.

**Applies to**
Style keywords

**Syntax**
SyntaxFromSql:

```
Style ( Left_Margin = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the size of the left margin in the units specified for the DataWindow</td>
</tr>
</tbody>
</table>

**Examples**

```
SQLCA.SyntaxFromSQL(sqlstring, &
'Style( ... LeftMargin = 500 ... )', errstring)
```

---

**Legend**

**Description**
The location of the legend in a Graph control in a DataWindow.

**Applies to**
Graph controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.graphname.Legend
```

**Describe and Modify argument:**

```
"graphname.Legend { = 'value' }"
```
Legend.DispAttr.fontproperty

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The name of the graph control for which you want to specify the location of the legend.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) A number indicating the location of the legend of a graph. Values are: 0 – None 1 – Left 2 – Right 3 – Top 4 – Bottom Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage

In the painter Select the control and set the value in the Properties view, General tab, Legend option (applicable when the graph has more than one series).

Examples

```powerbuilder
  string setting
  setting = dw1.Object.graph_1.Legend
  dw1.Object.graph_1.Legend = 2

  setting = dw1.Describe("graph_1.Legend")
  dw1.Modify("graph_1.Legend=2")
  dw1.Modify("graph_1.Legend='2-tIf(dept_id=200,0,2)'")
```

Legend.DispAttr.fontproperty

See DispAttr.fontproperty.

Level

Description The grouping level.

Level is used in DataWindow syntax only for the Create method.

Applies to Group keywords

Syntax Group ( BY( colnum1, colnum2, ... ) ... Level = n ... )
**LineRemove**

*Description*  
(RichText presentation style only) Whether the line of text that contains the input field for the column or computed field is removed when the input field is empty. LineRemove is similar to the SlideUp property for controls in other presentation styles.

*Applies to*  
Column and Computed Field controls in the RichText presentation style

*Syntax*  
PowerBuilder dot notation:

```
dw_control/Object/controlname.LineRemove
```

Describe and Modify argument:

```
"controlname.LineRemove { = 'value' }"
```

**Parameter** | **Description**
--- | ---
`controlname` | The name of the column or computed field whose line of text you want removed when the input field is empty.

`value` | `(exp)` Whether the line of text is removed so that the rest of the text slides up when the input field for `controlname` is empty. Values are:

- Yes – The line of text will be removed when the input field is empty.
- No – The line of text will not be removed.

*Value* can be a quoted DataWindow expression.

**Examples**

```powershell
string setting
setting = dw1/Object.emp_street2.LineRemove
dw1/Object.emp_street2.LineRemove = true
setting = dw1.Describe("emp_street2.LineRemove")
dw1.Modify("emp_street2.LineRemove=yes")
```

**LinkUpdateOptions**

*Description*  
When the OLE Object control is linked, the method for updating the link information. If the user tries to activate the OLE object and PowerBuilder cannot find the linked file, which breaks the link, LinkUpdateOptions controls whether PowerBuilder automatically displays a dialog box prompting the user to find the file. If you turn off the automatic dialog box, you can reestablish the link by calling the LinkTo or LinkUpdateDialog in code.

*Applies to*  
OLE Object controls
**Message.Title**

**Syntax**

PowerBuilder dot notation:

\[ dw_{-}control.\text{Object.olecontrolname}.\text{LinkUpdateOptions} \]

Describe and Modify argument:

"\text{olecontrolname}.\text{LinkUpdateOptions} \{ = 'updatetype' \}"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{olecontrolname}</td>
<td>The name of the OLE Object control for which you want to get or set the link update method.</td>
</tr>
<tr>
<td>\text{updatetype}</td>
<td>A number specifying how broken links will be reestablished. \text{Updatetype} can be a quoted DataWindow expression.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>• LinkUpdateAutomatic!</td>
</tr>
<tr>
<td></td>
<td>• LinkUpdateManual!</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  Select the control and set the value in the Properties view, Options tab, Link Update option.

**Examples**

string \text{ls\_data}

\text{ls\_data} = \text{dw1.\text{Object.ole\_report}.\text{LinkUpdateOptions}}

\text{dw1.\text{Object.ole\_report}.\text{LinkUpdateOptions} = 0}

\text{ls\_data} = \text{dw1.\text{Describe}('\text{ole\_report.\text{LinkUpdateOptions}')}}

\text{dw1.\text{Modify}('\text{ole\_report.\text{LinkUpdateOptions}='0'\}')}

---

**Message.Title**

**Description**

The title of the dialog box that displays when an error occurs.

**Applies to**  DataWindows

**Syntax**

PowerBuilder dot notation:

\[ dw_{-}control.\text{Object.DataWindow.Message.Title} \]

Describe and Modify argument:

"DataWindow.Message.Title \{ = 'titlestring' \}"

**SyntaxFromSql:**

DataWindow(Message.Title = 'titlestring ')

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>titlestring</td>
<td>A string containing the title for the title bar of the DataWindow dialog box that displays when an error occurs</td>
</tr>
</tbody>
</table>
Examples

setting = dw1.Object.DataWindow.Message.Title
dw1.Object.DataWindow.Message.Title = "Mistake!"

setting = dw1.Describe("DataWindow.Message.Title")
dw1.Modify("DataWindow.Message.Title='Bad, Bad, Bad'")

SQLCA.SyntaxFromSQL(sql_syntax, &
"Style(...) &
DataWindow(Message.Title='Sales Report' ...) ...", &
ls_Errors)

**Moveable**

**Description**
Whether the specified control in the DataWindow can be moved at runtime. Moveable controls should be in the DataWindow’s foreground.

**Applies to**
Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.controlname.Moveable
```

Describe and Modify argument:

```
"controlname.Moveable { = number }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The control within the DataWindow for which you want to get or set the Moveable property that governs whether the user can move the control</td>
</tr>
<tr>
<td>number</td>
<td>A boolean number specifying whether the control is moveable. Values are: 0 – False, the control is not moveable. 1 – True, the control is moveable.</td>
</tr>
</tbody>
</table>

**Usage**
In the painter Select the control and set the value in the Properties view, Position tab.

**Examples**

string setting
setting = dw1.Object.bitmap_1.Moveable
dw1.Object.bitmap_1.Moveable = 1

setting = dw1.Describe("bitmap_1.Moveable")
dw1.Modify("bitmap_1.Moveable=1")
**Multiline**

**Description**

(RichText presentation style) Whether the column or computed field can contain multiple lines. Multiline is effective only when Width.AutoSize is set to No.

**Applies to**

Column and Computed Field controls in the RichText presentation style

**Syntax**

PowerBuilder dot notation:

\[ dw\_control.\text{Object}.\text{controlname}.\text{Multiline} \]

Describe and Modify argument:

\[ "\text{controlname}.\text{Multiline} \{ = \text{value} \}" \]

**Parameter** | **Description**
--- | ---
controlname | The name of the column or computed field that will contain multiple lines.
value | (exp) Whether the input field can contain multiline lines. Values are:
  - Yes – The input field can contain multiple lines.
  - No – The input field cannot contain multiple lines.
  Value can be a quoted DataWindow expression.

**Usage**

**In the painter** Select the control and set the value in the Properties view, Input Field or Compute tab, MultiLine option.

To display the property sheet, click the input field (column or computed field) to select it. Then right-click and select Properties from the pop-up menu.

**Examples**

```
string setting
setting = dw1.Object.emp_street2.Multiline
dw1.Object.emp_street2.Multiline = true

setting = dw1.Describe("emp_street2.Multiline")
dw1.Modify("emp_street2.Multiline=yes")
```
### Name

**Description**  
The name of the control.

**Applies to**  
Button, Column, Computed Field, Graph, GroupBox, InkPicture, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**  
PowerBuilder dot notation:

\[
dw\_control.Object.controlname.Name
\]

Describe argument:

"controlname.Name"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The control for which you want the name. For columns, you can specify the column number preceded by #.</td>
</tr>
</tbody>
</table>

**Usage**  
**In the painter**  
Select the control and set the value in the Properties view, General tab, Name option.

**Examples**  
setting = dw1.Object.#4.Name  
setting = dw1.Describe("#4.Name")

### Nest_Arguments

**Description**  
The values for the retrieval arguments of a nested report. The number of values in the list should match the number of retrieval arguments defined for the nested report.

**Applies to**  
Report controls

**Syntax**  
PowerBuilder dot notation:

\[
dw\_control.Object.reportname.Nest\_Arguments
\]

Describe and Modify argument:

"reportname.Nest\_Arguments { = list ] "

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reportname</td>
<td>The name of the nested report for which you want to supply retrieval argument values.</td>
</tr>
</tbody>
</table>
| list        | A list of values for the retrieval arguments of the nested report. The format for the list is:  
\[
( ("arg1") ,("arg2") ,("arg3") {,....} ) )
\]
**Nested**

**Usage**

The list is not a quoted string. It is surrounded by parentheses, and each argument value within the list is parenthesized, surrounded with double quotes, and separated by commas. If an argument is a literal string, use single quotes within the double quotes.

When changing the values for the retrieval arguments, you must supply values for all the retrieval arguments defined for the report. If you specify fewer or more arguments, an error will occur at runtime when the DataWindow retrieves its data.

To remove the report’s retrieval arguments, specify empty parentheses. If no arguments are specified, the user is prompted for the values at runtime.

**In the painter** Select the control and set the value in the Properties view, General tab.

**Examples**

```powerbuilder
setting = dw1.Object.rpt_1.Nest_Arguments
dw1.Object.rpt_1.Nest_Arguments = & "((~"cust_id~"), (~'Eastern'~'))"

setting = dw1.Describe("rpt_1.Nest_Arguments")
dw1.Modify("rpt_1.Nest_Arguments" "=((~"cust_id~"), (~"Eastern'~"))")
dw1.Modify("rpt_1.Nest_Arguments=()")
```

---

**Nested**

**Description** Whether the DataWindow contains nested DataWindows. Values returned are Yes or No.

**Applies to** DataWindows

**Syntax** PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Nested
```

**Describe argument:**

"DataWindow.Nested"

**Examples**

```powerbuilder
string setting
setting = dw1.Object.DataWindow.Nested

setting = dw1.Describe("DataWindow.Nested")
```
NewPage (Group keywords)

Description  Whether a change in the value of a group column causes a page break.
Applies to  Group keywords
Syntax  SyntaxFromSql:
          
          Group ( colnum1, colnum2 NewPage )
Examples  SQLCA.SyntaxFromSQL(sql_syntax, &
          "Style(Type=Group) " + &
          "Group(#3 NewPage ResetPageCount)", &
          ls_Errors)

NewPage (Report controls)

Description  Whether a nested report starts on a new page. NewPage applies only to reports
in a composite DataWindow. Note that if the Trail_Footer property of the
preceding report is set to No, the current report will be forced to begin on a new
page regardless of the NewPage value.
Applies to  Report controls
Syntax  PowerBuilder dot notation:
          
          dw_control.Object.reportname.NewPage
Describe and Modify argument:
          
          "reportname.NewPage { = value } "

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reportname</td>
<td>The name of the report control for which you want to get or set the NewPage property.</td>
</tr>
<tr>
<td>value</td>
<td>Whether the report begins a new page.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Start the report on a new page.</td>
</tr>
<tr>
<td></td>
<td>No – Do not start the report on a new page.</td>
</tr>
</tbody>
</table>

Usage  In the painter  Select the Report control in the Composite presentation style
and set the value in the Properties view, General tab, New Page check box.
Examples  

```powershell
string newpage_setting
newpage_setting = dw1.Object.rpt_1.NewPage
dw1.Object.rpt_1.NewPage = "Yes"

newpage_setting = dw1.Describe("rpt_1.NewPage")
dw1.Modify("rpt_1.NewPage=Yes")
```
**NoUserPrompt**

**Description**
Determines whether message boxes are displayed to the user during DataWindow processing.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.NoUserPrompt
```

Describe and Modify argument:

```
"DataWindow.NoUserPrompt { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>A string specifying whether any message box requiring user intervention displays during DataWindow processing. Values are: Yes – No message box displays. No – (Default) Message boxes display when invoked during DataWindow processing.</td>
</tr>
</tbody>
</table>

**Usage**
Set the NoUserPrompt property to yes if the DataWindow is to be used in a batch process or in an EAServer environment when there is no possibility of end-user intervention. Dialog boxes you can prevent from displaying include the Error, Print, Retrieve, CrossTab, Expression, SaveAs, Import, Query, RichText, Filter, and Sort dialog boxes.

**Examples**
```
dw1.Object.DataWindow.NoUserPrompt = "yes"
dw1.Modify("DataWindow.NoUserPrompt=no")
```

**Objects**

**Description**
A list of the controls in the DataWindow object. The names are returned as a tab-separated list.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Objects
```

Describe argument:

```
"DataWindow.Objects"
```

**Examples**
```
setting = dw1.Describe("DataWindow.Objects")
```
OLE.Client.property

Description
Settings that some OLE server applications use to identify the client’s information. The property values can be used to construct the title of the server window.

Applies to
DataWindows

Syntax
PowerBuilder dot notation:
```
dw_control.Object.DataWindow.OLE.Client.property
```

Describe and Modify argument:
```
"DataWindow.OLE.Client.property { = 'value' }"
```

Usage
In the painter
Select the control and set the value in the Properties view, Definition tab.

Examples
```
ls_data = dw1.Object.DataWindow.OLE.Client.Class
dw1.Object.DataWindow.OLE.Client.Class = "PB"
ls_data = dw1.Describe("DataWindow.OLE.Client.Class")
dw1.Modify("DataWindow.OLE.Client.Class = 'PB'")
```

OLEClass

Description
The name of the OLE class for the TableBlob control.

Applies to
TableBlob controls

Syntax
PowerBuilder dot notation:
```
dw_control.Object.tblobname.OLEClass
```

Describe and Modify argument:
```
"tblobname.OLEClass { = 'oleclassname' }"
```
OverlapPercent

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tblobname</td>
<td>The TableBlob column for which you want to get or set the class of server application.</td>
</tr>
<tr>
<td>oleclassname</td>
<td>(exp) A string specifying a class of an OLE server application installed on your system. Oleclassname is quoted and can be a DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage

In the painter Select the control and set the value in the Properties view, Definition tab, OLE Class: Description option.

Examples

setting = dw1.Object.blob_1.OLEClass
dw1.Object.blob_1.OLEClass = 'Word.Document'

setting = dw1.Describe("blob_1.OLEClass")
dw1.Modify("blob_1.OLEClass='Word.Document'")

OverlapPercent

Description

The percentage of overlap for the data markers (such as bars or columns) in different series in a graph.

Applies to

Graph controls

Syntax

PowerBuilder dot notation:

```
dw_control.Object.graphname.OverlapPercent
```

Describe and Modify argument:

```
"graphname.OverlapPercent { = 'integer' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The name of the graph control in the DataWindow object for which you want to get or set the percentage of overlap.</td>
</tr>
<tr>
<td>integer</td>
<td>(exp) An integer specifying the percent of the width of the data markers that will overlap. Integer can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage

In the painter Select the control and set the value in the Properties view, General tab, OverlapPercent option (applicable when a series has been specified).

Examples

string setting

setting = dw1.Object.graph_1.OverlapPercent
dw1.Object.graph_1.OverlapPercent = 25

setting = dw1.Describe("graph_1.OverlapPercent")
dw1.Modify("graph_1.OverlapPercent=25")
**Pen.property**

**Description**
Settings for a line or the outline of a control.

**Applies to**
Line, Oval, Rectangle, and RoundRectangle controls

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.controlname.Pen.property
```

Describe and Modify argument:
```
"controlname.Pen.property { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control whose Pen property you want to get or set.</td>
</tr>
<tr>
<td>property</td>
<td>A property that applies to the Pen characteristics of controlname, as listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value of the property, as shown in the table below. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Property for Pen**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Color</td>
<td>(exp) A long specifying the color (the red, green, and blue values) to be used as the control’s line color. Painter: Pen Color option.</td>
</tr>
<tr>
<td>Style</td>
<td>(exp) A number specifying the style of the line. Values are: 0 – Solid 1 – Dash 2 – Dotted 3 – Dash-dot pattern 4 – Dash-dot-dot pattern 5 – Null (no visible line) Painter: Pen Style option.</td>
</tr>
<tr>
<td>Width</td>
<td>(exp) A number specifying the width of the line in the unit of measure specified for the DataWindow. Painter: Pen Width option (not available when Style is a value other than Solid).</td>
</tr>
</tbody>
</table>

**Usage**

In the painter Select the control and set values in the Properties view. General tab.

**Examples**
```
string setting
setting = dw1.Object.line_1.Pen.Width
dw1.Object.line_1.Pen.Width = 10
setting = dw1.Describe("line_1.Pen.Width")
dw1.Modify("line_1.Pen.Width=10")
```
Perspective

Description
The distance from the front of the window at which the graph appears.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:

\[ dw\_control.Object.graphname.Perspective \]

Describe and Modify argument:

\[ "graphname.Perspective \{ = \text{'integer'} \}" \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The name of the graph control in the DataWindow object for which you want to get or set the perspective.</td>
</tr>
<tr>
<td>integer</td>
<td>((exp)) An integer between 1 and 100 specifying how far away the graph appears. The larger the number, the greater the distance and the smaller the graph appears. Integer can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage
In the painter
Select the control and set the value in the Properties view, General tab, Perspective scroll bar (available when a 3D graph type is selected).

Examples

```powerbuilder
string setting
setting = dw1.Object.graph_1.Perspective

dw1.Object.graph_1.Perspective = 20

setting = dw1.Describe("graph_1.Perspective")
dw1.Modify("graph_1.Perspective=20")
```

Picture

Description
Settings that control the background picture displayed in a DataWindow object. Picture properties are not supported in Web Forms applications or in RichText, Graph, or OLE DataWindow presentation styles.

Applies to
DataWindows

Syntax
PowerBuilder dot notation:

\[ dw\_control.Object.datawindow.picture\_property \]

Describe and Modify argument:

\[ "DataWindow.picture.property \{ = \text{value} \}" \]
**Parameter** | **Description**
---|---
property | A property for the picture background. Properties and their settings are listed in the table that follows. Picture properties are used only when the datawindow.brushmode value is 6. These properties are not available for RichText, Graph, or OLE DataWindow objects.
value | The value to be assigned to the property. For picture properties, value can be a quoted DataWindow expression.

### Property for Picture

<table>
<thead>
<tr>
<th>Property for Picture</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clip.Bottom</td>
<td>An integer specifying the percentage to clip from the bottom edge of the background picture. Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>Clip.Left</td>
<td>An integer specifying the percentage to clip from the left edge of the background picture. Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>Clip.Right</td>
<td>An integer specifying the percentage to clip from the right edge of the background picture. Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>Clip.Top</td>
<td>An integer specifying the percentage to clip from the top edge of the background picture. Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>File</td>
<td>A string indicating the pathname for the picture file to be used for the DataWindow background. Supported formats are BMP, GIF, JPEG, RLE, WMF, and PNG. Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>Mode</td>
<td>An integer indicating the orientation and size of the background picture, and whether it is tiled. Tiling also depends on the Scale.X and Scale.Y values. Values are: 0 – Original Size 1 – Fit to Width 2 – Fit to Height 3 – Preserve Aspect Ratio/Max to Rect 4 – Stretch to Fit 5 – Tile 6 – Flip X 7 – Flip Y 8 – Flip XY Painter: Background tab, Picture group.</td>
</tr>
</tbody>
</table>
**Picture.property**

**Property for Picture**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale.X</td>
<td>An integer from 0 to 100 that indicates the horizontal size of the bitmap in relation to the horizontal size of the DataWindow object. If you set the Scale.X and Scale.Y properties to 100, the background picture will cover the entire DataWindow object. This property is used only when picture.tilemode is set to 5, 6, 7, or 8.</td>
<td>Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>Scale.Y</td>
<td>An integer from 0 to 100 that indicates the vertical size of the bitmap in relation to the vertical size of the DataWindow object. If you set the Scale.X and Scale.Y properties to 100, the background picture will cover the entire DataWindow object. This property is used only when picture.tilemode is set to 5, 6, 7, or 8.</td>
<td>Painter: Background tab, Picture group.</td>
</tr>
<tr>
<td>Transparency</td>
<td>An integer in the range 0 to 100, where 0 means that the background bitmap is opaque and 100 that it is completely transparent.</td>
<td>Painter: Background tab, Picture group.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  Select the DataWindow object and set the value on the Background tab of the Properties view.

If you save to an EMF or WMF, the properties on the Background tab are not saved with the DataWindow.

This table explains the values for Picture.Mode:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - Original Size</td>
<td>The image is centered and not tiled to fit the DataWindow.</td>
</tr>
<tr>
<td>1 - Fit to Width</td>
<td>The image is stretched or compressed (depending on the aspect ratio) until its width matches that of the DataWindow control.</td>
</tr>
<tr>
<td>2 - Fit to Height</td>
<td>The image is stretched or compressed (depending on the aspect ratio) until its height matches that of the DataWindow control.</td>
</tr>
<tr>
<td>3 - Preserve Aspect Ratio/Max to Rect</td>
<td>The image is stretched or compressed (without distortion) until its width or height matches that of the DataWindow control without either of them exceeding the bounds of the DataWindow control.</td>
</tr>
<tr>
<td>4 - Stretch to Fit</td>
<td>The image is stretched to fill the DataWindow control, without preserving the aspect ratio.</td>
</tr>
<tr>
<td>5 - Tile</td>
<td>The image is tiled to fill the DataWindow. The number of repetitions will be affected by the values of picture.scale.x, picture.scale.y, and the picture.clip properties.</td>
</tr>
</tbody>
</table>
CHAPTER 3  

DataWindow Object Properties

### Examples

```plaintext
dw_1.Modify("datawindow.brushmode=6")
dw_1_Object.datawindow.picture.File="MyPic.bmp"
```

### Pie DispAttr. fontproperty

See DispAttr.fontproperty.

### PlotNullData

**Description**

Whether a continuous line is drawn between tics in a line graph when there is no data on the X and Y axes.

**Applies to**

Graph controls, Graph DataWindow objects

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.graphname.PlotNullData
```

Describe and Modify argument:

```
"graphname.PlotNullData { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>graphname</code></td>
<td>The name of the graph control in the DataWindow object for which you want to get or set the perspective.</td>
</tr>
</tbody>
</table>
**Pointer**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| value     | A boolean number indicating whether a continuous line is drawn between tics in a line graph when there is no data. Values are:  
0 – (False) The line is broken when there is no data.  
1 – (True) The line is continuous. |

**Usage**  
*In the painter* Set the value in the Properties view, General tab, PlotNullData check box (available when a line graph type is selected).

**Examples**

```powerbuilder
    string setting
    setting = dw1.Object.graph_1.PlotNullData
    dw1.Object.graph_1.PlotNullData = 1
    setting = dw1.Describe("graph_1.PlotNullData")
    dw1.Modify("graph_1.PlotNullData=1")
```

**Pointer**  
*Description* The image to be used for the mouse pointer when the pointer is over the specified control. If you specify a pointer for the whole DataWindow, PowerBuilder uses that pointer except when the pointer is over a control that also has a Pointer setting.

*Applies to* DataWindow, Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

*Syntax*  
PowerBuilder dot notation:

```powerbuilder
dw_control.Object.controlname.Pointer
```

Describe and Modify argument:

```powerbuilder
"controlname.Pointer { = 'pointername' }
"```
### DataWindow Object Properties

**PrintPreview.property**

**Description**
Properties that control the print preview of a DataWindow.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

\[ \text{dw}_\text{control}.\text{Object.DataWindow.PrintPreview.property} \]

Describe and Modify argument:

\[ \text{"DataWindow.PrintPreview.property \{ = value \}"} \]

**SyntaxFromSql:**

\[ \text{DataWindow ( PrintPreview.property = value )} \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for print preview. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. Value cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>
### Property for Print.Preview

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buttons</td>
<td>Whether buttons display in print preview. Values are: Yes – Buttons are displayed. No – (Default) Buttons are not displayed.</td>
</tr>
<tr>
<td></td>
<td>Painter: Display Buttons – Print Preview.</td>
</tr>
<tr>
<td>Outline</td>
<td>Whether a blue line displays to show the location of the margins. Values are: Yes – (Default) Margin outline is displayed. No – Margin outline is not displayed.</td>
</tr>
<tr>
<td></td>
<td>Painter: Print Preview Shows Outline</td>
</tr>
<tr>
<td>Rulers</td>
<td>Whether the rulers display when the DataWindow object displays in preview mode. Values are: Yes – Display the rulers. No – (Default) Do not display the rulers.</td>
</tr>
<tr>
<td></td>
<td>You can view rulers in Preview mode in the DataWindow painter. With the Preview view selected, select File&gt;Print Preview, then File&gt;Print Preview Rulers. However, the setting is not used at runtime. To see rulers at runtime, set Print.Preview.Rulers in code.</td>
</tr>
<tr>
<td>Zoom</td>
<td>An integer indicating the zoom factor of the print preview. The default is 100%. You can view different zoom percentages in Preview mode in the DataWindow painter. With the Preview view selected, select File&gt;Print Preview, then File&gt;Print Preview Zoom. However, the setting is not used at runtime. To change the zoom factor at runtime, set Print.Preview.Zoom in code.</td>
</tr>
</tbody>
</table>

### Usage

**In the painter**  Select the DataWindow by deselecting all controls; then set values in the Properties view, Print Specifications tab.

**Examples**

```powerbuilder
setting = dw1.Describe
    ("DataWindow.Print.Preview.Buttons")
setting = dw1.Describe
    ("DataWindow.Print.Preview.Rulers")
```

### See also

Print.property
Print.

**Print.property**

**Description**
Properties that control the printing of a DataWindow.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.DataWindow.Print.property
```

Describe and Modify argument:
```
"DataWindow.Print.property { = value }"
```

Syntax From Sql:
```
DataWindow ( Print.property = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for printing. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property. Value cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>

### Property for Print

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Background</strong></td>
<td>Whether the background settings of the DataWindow and controls display on the printed report.</td>
</tr>
<tr>
<td>Values are:</td>
<td>Yes – Display background on report. This feature is not supported when you use a picture as the DataWindow background.</td>
</tr>
<tr>
<td></td>
<td>No – (Default) Do not display background on report.</td>
</tr>
<tr>
<td></td>
<td>Painter: Print Shows Background option.</td>
</tr>
</tbody>
</table>

| **Buttons** | Whether buttons display on the printed output. |
| Values are: | Yes – Buttons are displayed. |
|             | No – Buttons are not displayed. |
|             | Painter: Display Buttons – Print. |

| **CanUseDefault** | Whether a report can be printed on the default system printer if the printer specified by the PrinterName property is not valid. |
| **Printer**       | Painter: Can Use Default Printer option. |
### Property for Print Value

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
</table>
| ClipText       | Whether the text of a static text field on a printed page is clipped to the dimensions of the text field when the text field has no visible border setting. Values are:  
|                | Yes – The printed text does not overrun the text field.  
|                | No – (Default) The entire text can overrun the text field. Text is automatically clipped for text fields with visible border settings even if this property is not set.  
|                | Painter: Clip Text option.                                                                                                           |
| Collate        | Whether printing is collated. Note that collating is usually slower since the print is repeated to produce collated sets. Values are:  
|                | Yes – (Default) Collate the pages of the print job.  
|                | No – Do not collate.  
|                | Painter: Collate Copies option.                                                                                                       |
| Color          | An integer indicating whether the printed output will be color or monochrome. Values are:  
|                | 1 – Color  
|                | 2 – Monochrome  
|                | The user can specify the value in the system’s Print dialog box if the printer driver supports it.                                   |
| Columns        | An integer specifying the number of newspaper-style columns the DataWindow will print on a page. For purposes of page fitting, the whole DataWindow is a single column. The default is 1.  
|                | Painter: Newspaper Columns Across option.                                                                                             |
| Columns.Width  | An integer specifying the width of the newspaper-style columns in the units specified for the DataWindow.  
|                | Painter: Newspaper Columns Width option.                                                                                                |
| Copies         | An integer indicating the number of copies to be printed. The user can also specify this value in the system’s Print Setup dialog box if the printer driver supports it.  
|                | If you use both the Print.Copies property and the Print Setup dialog box to indicate that multiple copies should be printed, the total number of copies printed is the product of the two values. |
| CustomPage.Length | A long indicating the desired length of a custom paper size for printing. Use this property in conjunction with Print.CustomPage.Width and with Paper.Size set to 256. |
| CustomPage.Width | A long indicating the desired width of a custom paper size for printing. Use this property in conjunction with Print.CustomPage.Length and with Paper.Size set to 256. |
### Property for Print

<table>
<thead>
<tr>
<th>Property for Print</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DocumentName</td>
<td>A string containing the name that will display in the print queue when the user sends the contents of the DataWindow object to the printer. Painter: Document Name option.</td>
</tr>
</tbody>
</table>
| Duplex             | An integer indicating duplex or double-sided printing for printers capable of duplex printing. Values are:  
  0 – Default  
  1 – Normal (nonduplex) printing  
  2 – Short-edge binding (the long edge of the page is horizontal)  
  3 – Long-edge binding (the long edge of the page is vertical)  
  The user can specify the value in the system’s Print dialog box if the printer driver supports it. |
<p>| Filename           | A string containing the name of the file to which you want to print the report. An empty string means send to the printer. Painter: Cannot be set in painter. |
| Margin.Bottom      | An integer indicating the width of the bottom margin on the printed page in the units specified for the DataWindow. You can set Margin.Bottom when using SyntaxFromSql to generate DataWindow syntax. Painter: Bottom Margin option. |
| Margin.Left        | An integer indicating the width of the left margin on the printed page in the units specified for the DataWindow. You can set Margin.Left when using SyntaxFromSql to generate DataWindow syntax. Painter: Left Margin option. |
| Margin.Right       | An integer indicating the width of the right margin on the printed page in the units specified for the DataWindow. You can set Margin.Right when using SyntaxFromSql to generate DataWindow syntax. Painter: Right Margin option. |
| Margin.Top         | An integer indicating the width of the top margin on the printed page in the units specified for the DataWindow. You can set Margin.Top when using SyntaxFromSql to generate DataWindow syntax. Painter: Top Margin option. |</p>
<table>
<thead>
<tr>
<th>Property for Print</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Orientation</td>
<td>An integer indicating the print orientation. This property has no effect if the computer has no default printer. Values are: 0 – The default orientation for your printer 1 – Landscape 2 – Portrait Painter: Paper Orientation option.</td>
</tr>
<tr>
<td>OverridePrintJob</td>
<td>Whether you want to override the print job print settings defined in the PrintOpen method with the print specifications of the DataWindow. Values are: Yes – Override the print job print settings. No – (Default) Do not override the print job print settings. Painter: Override Print Job option.</td>
</tr>
<tr>
<td>Page.Range</td>
<td>A string containing the numbers of the pages you want to print, separated by commas. You can also specify a range with a dash. For example, to print pages 1, 2, and 5 through 10, enter: &quot;1,2, 5-10&quot;. The empty string means print all. The user can specify the value in the system’s Print dialog box if the printer driver supports it.</td>
</tr>
<tr>
<td>Page.RangeInclude</td>
<td>An integer indicating what pages to print within the desired range. Values are: 0 – Print all. 1 – Print all even pages. 2 – Print all odd pages. The user can specify the value in the system’s Print dialog box if the printer driver supports it.</td>
</tr>

<tr>
<td></td>
<td>255, 256 – User-defined paper size (see &quot;Usage&quot; below)</td>
</tr>
</tbody>
</table>

Painter: Paper Size option.
<table>
<thead>
<tr>
<th>Property for Print</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paper.Source</td>
<td>An integer indicating the bin that will be used as the paper source. The integer you use depends on the tray number used by the printer. (To determine the actual bin setting, you can query the printer with a utility that makes API calls to the printer driver.) Typical values are: 0 – Default 1 – Upper 2 – Lower 3 – Middle 4 – Manual 5 – Envelope 6 – Envelope manual 7 – Auto 8 – Tractor 9 – Smallfmt 10 – Largefmt 11 – Large capacity 14 – Cassette Painter: Paper Source option.</td>
</tr>
<tr>
<td>Preview</td>
<td>Whether the DataWindow object is displayed in preview mode. Values are: Yes – Display in preview mode. No – (Default) Do not display in preview mode.</td>
</tr>
<tr>
<td>Preview.Background</td>
<td>Whether the background settings of the DataWindow and controls display in the print preview. Values are: Yes – Display in preview mode. No – (Default) Do not display in preview mode. Painter: Preview Shows Background option.</td>
</tr>
<tr>
<td>PrinterName</td>
<td>A string containing the name of the printer you want to use to print the DataWindow report. If the printer name is not specified or if the named printer cannot be found at runtime, print output can be directed to the default printer for the user’s machine by setting the CanUseDefaultPrinter property. Otherwise, an error is returned. Painter: Printer Name option.</td>
</tr>
</tbody>
</table>
Usage

In the painter  Select the DataWindow by deselecting all controls; then set values in the Properties view, Print Specifications tab.

For example:

```c
// DataWindow Units set to 1/1000 inch
//9.875 inches long
```
```c
//7.375 inches wide
dw1.Modify("DataWindow.Print.CustomPage.Width=7375")
```
With Paper.Size set to 256, Length and Width are in millimeters:

```powerbuilder
```

Examples

```powerbuilder
   strData = dw1.Object.DataWindow.Print.Scale
   strData = dw1.Describe("DataWindow.Print.Scale")
   dw1.Modify("DataWindow.Print.Paper.Size = 3")
   dw1.Modify("DataWindow.Print.Margin.Top=500")
   setting = dw1.Describe("DataWindow.Print.Buttons")
   dw1.Modify("DataWindow.Print.Buttons = 'Yes'")
```

See also

Print.Preview.property

---

**Printer**

**Description**
The name of the printer for printing the DataWindow as specified in the system's printer selection dialog box.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
   dw_control.Object.DataWindow.Printer = "printername"
```

Describe and Modify argument:

```
   "DataWindow.Printer" { = printername }
```

**Parameter** | **Description**
---|---
printername | Name of the printer you want to use for your DataWindow

**Usage**
The printer you select for a DataWindow does not affect the PowerBuilder default printer or the system default printer. To specify a network-connected printer, you must use a fully specified network printer name:

```
   dw1.Object.DataWindow.Printer = "\net-print\pr-6"
```

If you specify a DataWindow printer, but the printer is not found, the DataWindow engine does not attempt to print to a default device.
Examples

The following example changes the DataWindow printer (but does not affect the system default printer device):

```powerbuilder
dw1.Modify ('DataWindow.Printer="My LaserJet 3" ')
```

You can display the DataWindow printer with either of the following calls:

```powerbuilder
string ls_dwprinter
ls_dwprinter = dw1.Object.DataWindow.Printer
ls_dwprinter = dw1.Describe("DataWindow.Printer")
```

### Processing

**Description**
The type of processing required to display the data in the selected presentation style.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```powerbuilder
dw_control.Object.DataWindow.Processing
```

Describe argument:

"DataWindow.Processing"

Return values are:

- 0 – (Default) Form, group, n-up, or tabular
- 1 – Grid
- 2 – Label
- 3 – Graph
- 4 – Crosstab
- 5 – Composite
- 6 – OLE
- 7 – RichText
- 8 – TreeView
- 9 – TreeView with Grid

**Examples**

```powerbuilder
string setting
setting = dw1.Object.DataWindow.Processing
setting = dw1.Describe("DataWindow.Processing")
```
**Protect**

**Description**
The protection setting of a column. The Protect property overrides tab order settings. When a column is protected, the user cannot edit it even if the column’s tab order is greater than 0.

**Applies to**
A column

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.columnname.Protect
```

Describe and Modify argument:

```
"columnname.Protect { = 'integer' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of the column for which you want to get or set the protection.</td>
</tr>
<tr>
<td>integer</td>
<td>(exp) A boolean integer specifying whether the column is protected.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>0 – False, the column is not protected.</td>
</tr>
<tr>
<td></td>
<td>1 – True, the column is protected.</td>
</tr>
<tr>
<td></td>
<td><em>Integer</em> can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**
A user cannot change a column value if any one of these conditions is true:

- TabSequence is 0
- Edit.DisplayOnly is Yes when the column has the Edit edit style
- Protect is 1

Only the Protect property allows you to specify a conditional expression that protects some values in the column but not others.

**In the painter**
Select the control and set the value in the Properties view, General tab (using a conditional expression).

**Examples**

```
string setting
setting = dw1.Object.emp_stat.Protect
dw1.Object.emp_stat.Protect=1
setting = dw1.Describe("emp_stat.Protect")
dw1.Modify("emp_stat.Protect=1")
dw1.Modify("emp_stat.Protect=1-tIf(IsRowNew(),0,1)")
```
## QueryClear

**Description**
Removes the `WHERE` clause from a query. Note that the only valid setting is Yes.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```plaintext
dw_control.Object.DataWindow.QueryClear
```

Modify argument:

```plaintext
"DataWindow.QueryClear { = value }"
```

### Examples

```plaintext
dw1.Object.DataWindow.QueryClear = "yes"
dw1.Modify("DataWindow.QueryClear=yes")
```

## QueryMode

**Description**
Whether the DataWindow is in query mode. In query mode, the user can specify the desired data by entering `WHERE` criteria in one or more columns.

**DataWindow presentation styles**
You cannot use QueryMode with DataWindow objects that use any of the following presentation styles: N-Up, Label, Crosstab, RichText, and Graph.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```plaintext
dw_control.Object.DataWindow.QueryMode
```

Describe and Modify argument:

```plaintext
"DataWindow.QueryMode { = value }"
```

### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether the DataWindow is in query mode.</td>
</tr>
</tbody>
</table>

Values are:
- Yes – Query mode is enabled.
- No – Query mode is disabled.
**QuerySort**

**Usage**

After the user specifies retrieval criteria in query mode, subsequent calls to `Retrieve` can use the new criteria. To retrieve data based on user selection, change the query mode back to No and use `AcceptText` to accept the user’s specification before the next call to `Retrieve`.

Setting `QuerySort` to Yes also puts the DataWindow into query mode, changing the `QueryMode` property’s value to Yes.

**Query mode and secondary DataWindows** When you are sharing data, you cannot turn on query mode for a secondary DataWindow. Trying to set the `QueryMode` or `QuerySort` properties results in an error.

**Buffer manipulation and query mode** A DataWindow cannot be in query mode when you call the `RowsCopy` method.

**Examples**

```powerbuilder
string setting
setting = dw1.Object.DataWindow.QueryMode
dw1.Object.DataWindow.QueryMode = "yes"
setting = dw1.Describe("DataWindow.QueryMode")
dw1.Modify("DataWindow.QueryMode=yes")
```

**QuerySort**

**Description**

Whether the result set is sorted when the DataWindow retrieves the data specified in query mode. When query sort is on, the user specifies sorting criteria in the first row of the query form.

**DataWindow presentation styles**

You cannot use `QuerySort` with DataWindow objects that use any of the following presentation styles: N-Up, Label, Crosstab, RichText, and Graph.

**Applies to** DataWindows

**Syntax** PowerBuilder dot notation:

```
dw_control.Object.DataWindow.QuerySort
```

Describe and Modify argument:

```
"DataWindow.QuerySort (= value)"
```
**Usage**

If the DataWindow is not already in query mode, setting QuerySort to Yes also sets QueryMode to Yes, putting the DataWindow in query mode.

When you set QuerySort to No, the DataWindow remains in query mode until you also set QueryMode to No.

**Query mode and secondary DataWindows**

When you are sharing data, you cannot turn on query mode for a secondary DataWindow. Trying to set the QueryMode or QuerySort properties results in an error.

**Examples**

```pascal
string setting
setting = dw1.Object.DataWindow.QuerySort

dw1.Object.DataWindow.QuerySort = "yes"

setting = dw1.Describe("DataWindow.QuerySort")
dw1.Modify("DataWindow.QuerySort=yes")
```

---

**RadioButtons.property**

**Description**

Properties that control the appearance and behavior of a column with the RadioButton edit style.

**Applies to**

Column controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.columnname.RadioButton.property
```

Describe and Modify argument:

```
"columnname.RadioButton.property { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The name of the column that has the RadioButton edit style.</td>
</tr>
<tr>
<td><code>property</code></td>
<td>A property for the RadioButton column. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to be assigned to the property. For RadioButton properties, <code>value</code> cannot be a DataWindow expression.</td>
</tr>
</tbody>
</table>
### Property for RadioButtons

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3D or ThreeD</td>
<td>Whether the radio buttons are 3D. Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Make the buttons 3D.</td>
</tr>
<tr>
<td></td>
<td>No – Do not make the buttons 3D.</td>
</tr>
<tr>
<td></td>
<td>Painter: 3D Look option.</td>
</tr>
<tr>
<td></td>
<td>When using dot notation, use the term ThreeD instead of 3D.</td>
</tr>
<tr>
<td>Columns</td>
<td>An integer constant specifying the number of columns of radio buttons.</td>
</tr>
<tr>
<td></td>
<td>Painter: Columns Across option.</td>
</tr>
<tr>
<td>LeftText</td>
<td>Whether the text labels for the radio buttons are on the left side.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – The text is on the left of the radio buttons.</td>
</tr>
<tr>
<td></td>
<td>No – The text is on the right of the radio buttons.</td>
</tr>
<tr>
<td></td>
<td>Painter: Left Text option.</td>
</tr>
<tr>
<td>Scale</td>
<td>Whether the circle is scaled to the size of the font. Scale has an effect only when 3D is No.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Scale the circles.</td>
</tr>
<tr>
<td></td>
<td>No – Do not scale the circles.</td>
</tr>
<tr>
<td></td>
<td>Painter: Scale Circles option.</td>
</tr>
</tbody>
</table>

### Usage

**In the painter**  
Select the control and set the value in the Properties view, Edit tab when Style Type is RadioButtons.

### Examples

```plaintext
setting = dw1.Describe("empg.RadioButtons.LeftText")
dw1.Modify("emp_gender.RadioButtons.LeftText=no")
dw1.Modify("emp_gender.RadioButtons.3D=Yes")

string setting
setting = &
    dw1.Object.emp_gender.RadioButtons.LeftText = "no"
```

### Range

**Description**  
The rows in the DataWindow used in the graph or OLE Object control. Range can be all rows, the rows on the current page, a group that you have defined for the DataWindow, or the current row (OLE Object controls only).

**Applies to**  
Graph and OLE Object controls
**DataWindow Object Properties**

**Syntax**

PowerBuilder dot notation:

```plaintext
dw_control.Object.controlname.Range
```

Describe argument:

"controlname.Range"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the graph control within the DataWindow that will display the graphed rows or the name of the OLE Object control that holds an OLE object to which the specified range of rows will be transferred.</td>
</tr>
</tbody>
</table>

**Usage**

Possible values are:

- `-2` – The current row (OLE Object controls only)
- `-1` – The rows on a single page in the DataWindow object
- `0` – All the rows in the DataWindow object
- `n` – The number of a group level in the DataWindow object

GroupBy and Target also affect the data that is transferred to the OLE object.

**In the painter**  Select the control and set the value in the Properties view, Data tab, Rows option.

**Examples**

```plaintext
string strRange
strRange = dw1.Object.graph_salary.Range
strRange = dw1.Object.ole_report.Range
strRange = dw1.Describe("graph_salary.Range")
strRange = dw1.Describe("ole_report.Range")
```

**ReadOnly**

**Description**

Whether the DataWindow is read-only.

**Applies to**

DataWindows

**Syntax**

PowerBuilder dot notation:

```plaintext
dw_control.Object>DataWindow.ReadOnly
```

Describe and Modify argument:

"DataWindow.ReadOnly { = value }"

DataWindow Reference 351
Render3D

Parameter | Description
---|---
value | Whether the DataWindow is read-only.
Values are:
Yes – Make the DataWindow read-only.
No – (Default) Do not make the DataWindow read-only.

Examples

```powerbuilder
string setting
setting = dw1.Object.DataWindow.ReadOnly
dw1.Object.DataWindow.ReadOnly="Yes"
setting = dw1.Describe("DataWindow.ReadOnly")
dw1.Modify("DataWindow.ReadOnly=Yes")
```

Render3D

Description | Whether the GraphType is rendered in the DirectX 3D style.
Applies to | Graph controls and Graph DataWindows
Syntax | PowerBuilder dot notation:
| `dw_control.Object.graphname.Render3D`
Describe and Modify argument:
| `"graphname.Render3D { = 'boolean' }`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `graphname` | The graph control for which you want to get or change the type. Graph types that can use the new 3D rendering style are:
| 3 – Bar 3D | 15 – Area3D |
| 8 – Col3D | 16 – Line3D |
| 17 – Pie3D |
| `boolean` | 0 = Original 3D style
1 = New 3D rendering style

Usage

In the painter | Select the control and set the value in the Properties view, General tab.

Examples

The following statement sets a graph control to the DirectX 3D style.

```powerbuilder
gr_1.Render3D=true
```
The following statement sets a DataWindow in the graph presentation style to the DirectX 3D style.

```
dw_1.Object.gr_1.Render3D=true
```

### ReplaceTabWithSpace

**Description**
Whether tab characters embedded in the data for a DataWindow display as square boxes when the row is not the current row.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.ReplaceTabWithSpace
```

Describe and Modify argument:

```
"DataWindow.ReplaceTabWithSpace { = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether tab characters embedded in the data for a DataWindow are replaced with spaces.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Replace each tab character with four spaces.</td>
</tr>
<tr>
<td></td>
<td>No – (Default) Do not replace tab characters.</td>
</tr>
</tbody>
</table>

**Examples**

```
string str
str = dw1.Object.DataWindow.ReplaceTabWithSpace
dw1.Object.DataWindow.ReplaceTabWithSpace="Yes"
str = dw1.Describe("DataWindow.ReplaceTabWithSpace")
dw1.Modify("DataWindow.ReplaceTabWithSpace=Yes")
```
Report
Description Whether the DataWindow is a read-only report.
Applies to Style keywords
Syntax SyntaxFromSql:
   Style ( Report = value )
   
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
   | value     | Whether the DataWindow is a read-only report, similar to a DataWindow created in the Report painter. Values are:
   |           | Yes – The DataWindow is a read-only report. |
   |           | No – The DataWindow is not read-only. |

Examples SQLCA.SyntaxFromSQL(sqlstring, & 'Style(...Report = yes ...)', errstring)

ResetPageCount
Description Specifies that a change in the value of the group column causes the page count to begin again at 0.
Applies to Group keywords
Syntax SyntaxFromSql:
   Group ( col1 { col2 ...} ... ResetPageCount )

Examples SQLCA.SyntaxFromSQL(sql_syntax, & "Style(Type=Group) " + & "Group(#3 NewPage ResetPageCount)", & errorvar)

Resizeable
Description Whether the user can resize the specified control.
Applies to Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls
Syntax PowerBuilder dot notation:
   dw_control.Object.controlname Resizeable
   
   Describe and Modify argument:
   "controlname.Resizeable { = value }"
CHAPTER 3  DataWindow Object Properties

Usage

In the painter  Select the control and set the value in the Properties view, Position tab.

When you make the control resizable, set the Border property to the resizable border so the user knows it is resizable.

Examples

string setting
setting = dw1.Object.graph_1.Resizeable
dw1.Object.graph_1.Resizeable = 1

setting = dw1.Describe("graph_1.Resizeable")
dw1.Modify("graph_1.Resizeable=1")
dw1.Modify("bitmap_1.Resizeable=0")

Retrieve

Description  The SQL statement for the DataWindow.

Retrieve is set in DataWindow syntax only for the Create method.

Applies to  Table keywords

Syntax  Table ( ... Retrieve = selectstatement ... )

Retrieve.AsNeeded

Description  Whether rows will be retrieved only as needed from the database. After the application calls the Retrieve method to get enough rows to fill the visible portion of the DataWindow, additional rows are "needed" when the user scrolls down to view rows that have not been viewed yet.

Applies to  DataWindows

Syntax  PowerBuilder dot notation:

dw_control.Object.DataWindow.Retrieve.AsNeeded
RichEdit.property

Describe and Modify argument:
"DataWindow.Retrieve.AsNeeded { = 'value' }

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether rows will be retrieved only as needed from the database. Values are: • Yes – Rows will be retrieved only as needed. • No – All rows will be retrieved when the Retrieve method is called.</td>
</tr>
</tbody>
</table>

Usage
In the painter
Set the value using Rows\Retrieve Options\Rows As Needed.

Examples

```
string setting
setting = dw1.Object.DataWindow.Retrieve.AsNeeded= "Yes"
```

```
setting = dw1.Describe("DataWindow.Retrieve.AsNeeded")
dw1.Modify("DataWindow.Retrieve.AsNeeded=Yes")
```

RichEdit.property

Description
Settings that affect the appearance and behavior of columns whose edit style is RichText.

Applies to
Column controls

Syntax
PowerBuilder dot notation:

dw_control.Object.columnname.RichEdit.property

Describe and Modify argument:
"columnname.RichEdit.property { = value }"

SyntaxFromSql:
Column ( RichEdit.property = value )

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The column with the RichText edit style for which you want to get or set property values. You can specify the column name or a pound sign (#) and the column number.</td>
</tr>
<tr>
<td>property</td>
<td>A property for the column’s Edit style. Properties and their settings are listed in the table below. The table identifies the properties you can use with SyntaxFromSql.</td>
</tr>
</tbody>
</table>
### Parameter for RichEdit

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value to be assigned to the property.</td>
</tr>
</tbody>
</table>

#### AutoSelect

Whether to select the contents of the column control automatically when it receives focus.

Values are:
- Yes – Select automatically.
- No – Do not select automatically.

You can use AutoSelect with SyntaxFromSql. The setting applies to all the columns in the generated syntax.

Painter: Auto Selection option

#### DisplayOnly

Whether the column is display only.

Values are:
- Yes – Do not allow the user to enter data; make the column display only.
- No – Allow the user to enter data.

For conditional control over column editing, use the Protect property.

Painter: Display Only option

#### FocusRectangle

Whether a dotted rectangle (the focus rectangle) surrounds the current row of the column when the column has focus.

Values are:
- Yes – Display the focus rectangle.
- No – Do not display the focus rectangle.

You can use FocusRectangle with SyntaxFromSql. The setting applies to all the columns in the generated syntax.

Painter: Show Focus Rectangle option

#### Limit

A number specifying the maximum number of characters (0 to 32,767) that the user can enter. 0 means unlimited.

Painter: Limit option

#### NilIsNull

Whether to set the value of the column control to null when the user leaves it blank.

Values are:
- Yes – Make the empty string null.
- No – Do not make the empty string null.

Painter: Empty String is Null option.
**RichText.property**

<table>
<thead>
<tr>
<th>Property for RichEdit</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>Whether the column is required. Values are: Yes – It is required. No – It is not required. Painter: Required option.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter** Select the control and set values in the Properties view, Edit tab, when Style Type is RichText.

**Examples**

```
string setting
setting = &
dw_1.Object.rte_description.RichEdit.VScrollBar="yes"
setting = dw_1.Describe(&
    "rte_description.RichEdit.VScrollBar")
dw_1.Modify("rte_description.RichEdit.Required=no")
```

---

**RichText.property**

**Description**
Properties for the DataWindow RichText presentation style.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:
```
dw_control.Object.DataWindow.RichText.property
```

Describe and Modify argument:
```
"DataWindow.RichText.property{ = value }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for the DataWindow RichText presentation style. Properties and appropriate values are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>A value to be assigned to the property.</td>
</tr>
</tbody>
</table>
### CHAPTER 3  DataWindow Object Properties

<table>
<thead>
<tr>
<th>Property for RichText</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BackColor</td>
<td>A long specifying the numeric value of the background color of the text editing area. Values are -2 to 16,777,215. For more information about color, see RGB. Painter: Background Color group, General option.</td>
</tr>
</tbody>
</table>
| ControlCharsVisible   | Specifies whether control characters (carriage returns, spaces, and tabs) are visible. Values are:  
• Yes – Control characters are visible.  
• No – Control characters are hidden.  
Painter: RichText Presentation group, ControlChars Visible option. |
| DisplayOnly           | Specifies whether users can make changes to the contents. Values are:  
• Yes – The content, including text and input files, is protected (the user cannot edit it).  
• No – The user can edit the content.  
Painter: Display Only option. |
| HeaderFooter          | (Read-only) Specifies whether the RichTextEdit DataWindow has a header/footer section. This property must be set in the painter and cannot be changed at runtime. Values are:  
• Yes – The control has a header/footer section.  
• No – The control does not have a header/footer section.  
If a document has a header or footer and the HeaderFooter property is set to no, then header/footer information in the document is ignored. If the document is then saved in the same file, the header/footer information is lost.  
Painter: Header/Footer option. |
| InputField BackColor  | A long specifying the default background color for all input fields: –2 to 16,777,215.  
Painter: Background Color group, Input Field option. |
| InputField NamesVisible | Specifies whether input field names are displayed in input fields, rather than the input field values. Values are:  
• Yes – Input fields display.  
• No – Input fields do not display.  
The value you specify is ignored when the InputFieldsVisible property is set to false.  
Painter: RichText Presentation group, Input Field Names Visible option. |
| InputFields Visible   | Specifies whether input fields display in the DataWindow object. Values are:  
• Yes – Input fields display their names.  
• No – Input fields display their data.  
Painter: RichText Presentation group, Input Fields Visible option. |
<table>
<thead>
<tr>
<th>Property for RichText</th>
<th>Value</th>
</tr>
</thead>
</table>
| PictureFrame         | Specifies whether pictures are displayed as empty frames. Values are:  
|                      | • Yes – Pictures are displayed as empty frames.  
|                      | • No – The pictures are displayed.  
|                      | Painter: Pictures As Frame option. |
| PopMenu              | Specifies whether the user has access to a pop-up menu by clicking the right mouse button on the DataWindow. The menu allows the user to cut and paste, insert a file, and select formatting options. Values are:  
|                      | • Yes – Pop-up menu is enabled.  
|                      | • No – Pop-up menu is disabled.  
|                      | Painter: PopUp Menu option. |
| ReadOnly             | Specifies whether the user can change the data and the text in the DataWindow. Values are:  
|                      | • Yes – The DataWindow is read-only (text and data cannot be modified).  
|                      | • No – The text and the data can be modified. |
| RulerBar             | Specifies whether a ruler bar is visible above the editing area. If visible, the user can use it to see measurements while setting tabs and margins on the tab bar (see the TabBar property in this table). Values are:  
|                      | • Yes – Ruler bar is visible.  
|                      | • No – Ruler bar is hidden.  
|                      | If the RichTextEdit pop-up menu is enabled, the user can use it to turn ruler bar display on and off (see the PopMenu property in this table).  
|                      | Painter: RichText Bars group, Ruler option. |
| SpacesVisible       | Specifies whether spaces are visible. Values are:  
|                      | • Yes – Spaces are visible.  
|                      | • No – Spaces are hidden.  
|                      | Painter: RichText Presentation group, Spaces Visible option. |
| TabBar               | Specifies whether a bar for setting tabs is visible above the editing area. Values are:  
|                      | • Yes – Tab bar is visible.  
|                      | • No – Tab bar is hidden.  
|                      | If the pop-up menu is enabled, the user can use it to turn tab bar display on and off (see the PopMenu property in this table).  
|                      | Painter: RichText Bars group, Tab option. |
| TabsVisible         | Specifies whether tabs are visible. Values are:  
|                      | • Yes – Spaces are visible.  
|                      | • No – Spaces are hidden.  
|                      | Painter: RichText Presentation group, Tabs Visible option. |
### DataWindow Object Properties

#### CHAPTER 3

**Usage**

In the painter Select the DataWindow by deselecting all controls; then set the value in the Properties view, General tab, when the presentation style is RichText.

**Examples**

```powerbuilder
define setting = &
define setting = &
    dw1.Describe("DataWindow.RichText.DisplayOnly")
```

### Rotation

**Description**
The degree of left-to-right rotation for the graph control within the DataWindow when the graph has a 3D type.

**Applies to**

Graph controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.graphname.Rotation
```

Describe and Modify argument:

```
"graphname.Rotation = { 'integer' }"
```
### Row.Resize

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>graphname</code></td>
<td>The name of the Graph control for which you want to get or set the rotation.</td>
</tr>
<tr>
<td><code>integer</code> (exp)</td>
<td>The degree of rotation for the graph. Effective values range from -90 to 90. Integer can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  
Select the control and set the value in the Properties view, General tab, Rotation scroll bar (enabled when a 3D graph type is selected).

**Examples**

```plaintext
string setting
setting = dw1.Object.graph_1.Rotation
dw1.Object.graph_1.Rotation=25

setting = dw1.Describe("graph_1.Rotation")
dw1.Modify("graph_1.Rotation=25")
dw1.Modify("graph_1.Rotation='1-tHour(Now())'")
```

### Row.Resize

**Description**  
Whether the user can use the mouse to change the height of the rows in the detail area of the DataWindow.

**Applies to**  
DataWindows

**Syntax**  
PowerBuilder dot notation:

```plaintext
```

**Describe** and **Modify** argument:

"DataWindow.Row.Resize { = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `value` | Whether the user can resize the rows in the detail area. Values are:  
  • 1 – Yes, the user can resize the rows.  
  • 0 – No, the user cannot resize the rows. |

**Usage**

**In the painter**  
Select the DataWindow by deselecting all controls; then set the value in the Properties view, General tab, Row Resize option (available when the presentation style is Grid or Crosstab).

**Examples**

```plaintext
string setting
dw1.Object.DataWindow.Row.Resize = 0

setting = dw1.Describe("DataWindow.Row.Resize")
dw1.Modify("DataWindow.Row.Resize=0")
```
**Rows_Per_Detail**

Description: The number of rows in the detail area of an n-up DataWindow object. This property should be 1 unless the Type property for the Style keyword is Tabular.

Applies to: DataWindows

Syntax: PowerBuilder dot notation:

\[ dw\_control\.Object\.DataWindow\.Rows\_Per\_Detail \]

Describe argument:

"DataWindow.Rows_Per_Detail"

SyntaxFromSql:

\[ \text{DataWindow (... Rows\_Per\_Detail = n ...)} \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>A long specifying the number of rows in each column</td>
</tr>
</tbody>
</table>

Examples:

\[ \text{SQLCA.SyntaxFromSQL(sqlselect, \\& 'DataWindow(...Rows\_Per\_Detail = 12 ...)', \\& errstring)} \]

**Selected**

Description: A list of selected controls within the DataWindow.

Applies to: DataWindows

Syntax: PowerBuilder dot notation:

\[ dw\_control\.Object\.DataWindow\.Selected \]

Describe and Modify argument:

"DataWindow.Selected = ' list' "

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( list )</td>
<td>A list of the controls you want to select. In the list you designate a group of controls by specifying a range of row numbers and a range of controls in the format: [ startrow/endrow/startcontrol/endcontrol ] To specify more than one group, separate each group with a semicolon: [ startrow1/endrow1/startobj1/endobj1:startrow2/endrow2/startobj2/endobj2;... ] Do not include spaces in the string. You must use column names, not column numbers.</td>
</tr>
</tbody>
</table>
**Selected.Data**

**Examples**

```
setting = dw1.Object.DataWindow.Selected
dw1.Object.DataWindow.Selected = &
"1/10/emp_id/emp_name;12/23/salary/status"

setting = dw1.Describe("DataWindow.Selected")
dw1.Modify("DataWindow.Selected=" &
"'1/10/emp_id/emp_name;12/23/salary/status'")
```

**Selected.Data**

**Description**

A list describing the selected data in the DataWindow. Each column’s data is separated by a tab and each row is on a separate line.

**Applies to**

DataWindows (Crosstab and Grid presentation styles only)

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Selected.Data
```

Describe argument:

```
"DataWindow.Selected.Data"
```

**Examples**

```
string setting
setting = dw1.Object.DataWindow.Selected.Data
setting = dw1.Describe("DataWindow.Selected.Data")
```

---

**Selected.Mouse**

**Description**

Whether the user can use the mouse to select columns.

**Applies to**

DataWindows

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Selected.Mouse
```

Describe and Modify argument:

```
"DataWindow.Selected.Mouse ( = value )"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether the user can use the mouse to select columns.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>• Yes – The mouse can be used.</td>
</tr>
<tr>
<td></td>
<td>• No – The mouse cannot be used.</td>
</tr>
</tbody>
</table>

---

364
Usage

**In the painter** Select the DataWindow by deselecting all controls; then set the value in the Properties view, General tab, Mouse Selection option (available when the presentation style is Grid or Crosstab).

**Examples**

```powershell
string setting
setting = dw1.Object.DataWindow.Selected.Mouse
dw1.Object.DataWindow.Selected.Mouse = "Yes"

setting = dw1.Describe("DataWindow.Selected.Mouse")
dw1.Modify("DataWindow.Selected.Mouse = Yes")
```

**Series**

See Axis, Axis.property, and DispAttr.fontproperty.

**ShadeColor**

**Description**

The color used for shading the back edge of the series markers when the graph’s type is 3D. ShadeColor has no effect unless Series.ShadeBackEdge is 1 (Yes). If ShadeBackEdge is 0, the axis plane is the same color as the background color of the graph.

**Applies to**

Graph controls

**Syntax**

PowerBuilder dot notation:

```powershell
dw_control.Object.graphname.ShadeColor
```

Describe and Modify argument:

```powershell
"graphname.ShadeColor { = 'long' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>graphname</code></td>
<td>The Graph control in the DataWindow for which you want to shade color.</td>
</tr>
<tr>
<td><code>long</code></td>
<td><em>(exp)</em> A long number converted to a string specifying the color of the shading for axes of a 3D graph. You can use the RGB function in a DataWindow expression or in PowerScript to calculate the desired color value. However, be sure to convert the return value of the PowerScript function to a string. <code>Long</code> can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>
Usage
To set the shade color for individual series markers, such as bars or pie slices, use the method `SetDataStyle`.

**In the painter** Select the control and set the value in the Properties view, General tab, Shade Color option.

**Examples**
```powerbuilder
definition
string setting
setting = dw1.Object.graph_1.ShadeColor
dw1.Object.graph_1.ShadeColor = 16600000
setting = dw1.Describe("graph_1.ShadeColor")
dw1.Modify("graph_1.ShadeColor=16600000")
dw1.Modify("graph_1.ShadeColor=String(RGB(90,90,90))")
dw1.Modify("graph_1.ShadeColor='0-t" &
  + If(salary>50000," &
    + String(RGB(100,90,90)) &
    + "," &
    + String(RGB(90,90,100)) &
    + ")'")"
```

**ShowBackColorOnXP**

**Description** Whether the background color that you select for a button displays on Windows XP.

**Applies to** DataWindow objects

**Syntax** PowerBuilder dot notation:
```
dw_control.Object.DataWindow.ShowBackColorOnXP
```

**Describe and Modify argument:**
```
"DataWindow.ShowBackColorOnXP( = value )"
```

**Parameter** | **Description**
--- | ---
`value` | A boolean value that indicates whether the background color that you select for a button displays on Windows XP. Values are:
  | Yes – Display the background color.
  | No – Do not display the background color (default).
Usage
The Background.Color property is not supported for buttons on Windows XP by default because the current XP theme controls the appearance of the button.

In the painter Set the Show Backcolor on XP property on the General tab of the Properties view for the DataWindow object. The background color you selected will display in Preview mode.

Examples
```
  dw1.Modify("DataWindow.ShowBackColorOnXP = yes")
  dw1.Object.DataWindow.ShowBackColorOnXP = "yes"
```

ShowBackground
Description Whether the background settings of the report display.
Applies to Report controls
Syntax PowerBuilder dot notation:
```
  dw_control.Object.controlname.ShowBackground
```
Describe and Modify argument:
```
  "controlname.ShowBackground{ = 'value' }"
```

Usage
In the painter Select the control and set the value in the Properties view, General tab, Show Background check box.

Examples
```
  dw1.Modify("r_orders_nested.ShowBackground = yes")
  dw1.Object.DataWindow.ShowBackground = "yes"
```

ShowDefinition
Description Whether the DataWindow definition will display. The DataWindow will display the column names instead of data.
Applies to DataWindows
SizeToDisplay

Syntax
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.ShowDefinition
```

Describe and Modify argument:

```
"DataWindow.ShowDefinition { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| value     | (exp) Whether the column names will display. Values are:
|           | • Yes – Display the column names.
|           | • No – Do not display the data, if any. Value can be a quoted DataWindow expression. |

Examples

```
string setting
setting = dw1.Object.DataWindow.ShowDefinition
dw1.Object.DataWindow.ShowDefinition = "Yes"

setting = dw1.Describe("DataWindow.ShowDefinition")
dw1.Modify("DataWindow.ShowDefinition=Yes")
```

SizeToDisplay

Description
Whether the graph should be sized automatically to the display area.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:

```
dw_control.Object.graphname.SizeToDisplay
```

Describe and Modify argument:

```
"graphname.SizeToDisplay { = 'value' }"
```
### SlideLeft

**Description**
Whether the control moves to the left when other controls to the left leave empty space available. This property is for use with read-only controls and printed reports. It should not be used with data entry fields or controls.

**Applies to**
Button, Column, Computed Field, Graph, GroupBox, Line, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.controlname.SlideLeft
```

Describe and Modify argument:

```
"controlname.SlideLeft { = 'value' }"
```
**SlideUp**

**Parameter** | **Description**
---|---
`controlname` | The name of the control for which you want to get or set the Slide setting.
`value` | *(exp)* Whether the control slides left when there is empty space to its left. Values are:
- Yes – The control will slide left into available space.
- No – The control will remain in position.
*Value* can be a quoted DataWindow expression.

**Usage**

In the painter  Select the control and set the value in the Properties view, Position tab, Slide Left check box. This property is not supported in Web DataWindows.

**Examples**

```plaintext
string setting
setting = dw1.Object.graph_1.SlideLeft
dw1.Object.emp_lname.SlideLeft = "yes"

setting = dw1.Describe("graph_1.SlideLeft")
dw1.Modify("emp_lname.SlideLeft=yes")
```

**SlideUp**

**Description**

Whether the control moves up when other controls above it leave empty space available. This property is for use with read-only controls and printed reports. It should not be used with data entry fields or controls.

**Applies to**

Button, Column, Computed Field, Graph, GroupBox, Line, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.controlname.SlideUp
```

Describe and Modify argument:

```
"controlname.SlideUp { = 'value' }"
```
DataWindow Object Properties

CHAPTER 3

Usage

In the painter  Select the control and set the value in the Properties view, Position tab, Slide Up check box. This property is not supported in Web DataWindows.

Examples

string setting
setting = dw1.Object.graph_1.SlideUp
dw1.Object.emp_lname.SlideUp = "no"

setting = dw1.Describe("graph_1.SlideUp")
dw1.Modify("emp_lname.SlideUp=no")

Sort

Description  Sort criteria for a newly created DataWindow. To specify sorting for existing DataWindows, see the SetSort and Sort methods.

Applies to  Table keywords in DataWindow syntax

Syntax  DataWindow syntax for Create method:

Table ( ... Sort = stringexpression ... )

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stringexpression</td>
<td>A string whose value represents valid sort criteria. See the SetSort method for the format for sort criteria. If the criteria string is null, PowerBuilder prompts for a sort specification when it displays the DataWindow.</td>
</tr>
</tbody>
</table>
**Spacing**

**Description**
The gap between categories in a graph.

**Applies to**
Graph controls

**Syntax**
PowerBuilder dot notation:

\[ \text{dw\_control}\!.\text{Object}\!.\text{graphname}\!.\text{Spacing} \]

Describe and Modify argument:

\[ "\text{graphname}\!.\text{Spacing} \{ = \ 'integer' \}" \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>The name of the graph control in the DataWindow for which you want to get or set the spacing.</td>
</tr>
<tr>
<td>integer</td>
<td>(exp) An integer specifying the gap between categories in the graph. You specify the value as a percentage of the width of the data marker. For example, in a bar graph, 100 is the width of one bar, 50 is half a bar, and so on. Integer can be a DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**
Select the control and set the value in the Properties view, General tab, Spacing option.

**Examples**

String setting

```
string setting
setting = dw1.Object.graph_1.Spacing
dw1.Object.graph_1.Spacing = 120

setting = dw1.Describe("graph_1.Spacing")
dw1.Modify("graph_1.Spacing=120")
```

**Sparse**

**Description**
The names of repeating columns that will be suppressed in the DataWindow.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

\[ \text{dw\_control}\!.\text{Object}\!.\text{DataWindow}\!.\text{Sparse} \]

Describe and Modify argument:

\[ "\text{DataWindow}\!.\text{Sparse} \{ = \ 'list' \}" \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>list</td>
<td>(exp) A tab-separated list of column names to be suppressed. List can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>
Create method (include at the end of the DataWindow syntax):

```
Sparse ( names = "col1~tcol2~tcol3 ...")
```

Usage **In the painter**  Set the value using Rows>Suppress Repeating Values. This property is not supported in Web DataWindows.

Examples

```
string setting
setting = dw1.Object.DataWindow.Sparse
dw1.Object.DataWindow.Sparse = 'col1~tcol2'
setting = dw1.Describe("DataWindow.Sparse")
dw1.Modify("DataWindow.Sparse='col1-tcol2'")
```

---

**Storage**

Description  The amount of virtual storage in bytes that has been allocated for the DataWindow object.

Applies to  DataWindows

Syntax  PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Storage
```

Describe argument:

```
"DataWindow.Storage"
```

Usage  **Canceling a query that uses too much storage**  You can check this property in the script for the RetrieveRow event in the DataWindow control and cancel a query if it is consuming too much storage.

Examples

```
string setting
setting = dw1.Object.DataWindow.Storage
setting = dw1.Describe("DataWindow.Storage")
IF Long(setting) > 50000 THEN RETURN 1
```

---

**StoragePageSize**

Description  The default page size for DataWindow storage.

Applies to  DataWindows

Syntax  PowerBuilder dot notation:

```
dw_control.Object.DataWindow.StoragePageSize
```
**Summary.property**

Describe and Modify argument:

"DataWindow.StoragePageSize { = 'size' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>Two values are provided to enable the DataWindow to use the available virtual memory most efficiently in the current environment:</td>
</tr>
<tr>
<td></td>
<td>• LARGE (Recommended)</td>
</tr>
<tr>
<td></td>
<td>• MEDIUM</td>
</tr>
</tbody>
</table>

**Usage**

Set this property to avoid out of memory errors when performing large retrieve, import, or RowsCopy operations. The property must be set before the operation is invoked.

**Examples**

dw1.Modify("datawindow.storagepagesize='LARGE'")
dw1.object.datawindow.storagepagesize='large'

**Summary.property**

See Bandname.property.

---

**SuppressEventProcessing**

**Description**

Whether the ButtonClicked or ButtonClicking event is fired for this particular button.

**Applies to**

Button controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.buttonname.SuppressEventProcessing
```

**Describe and Modify argument:**

"buttonname.SuppressEventProcessing { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buttonname</td>
<td>The name of the button control for which you want to suppress event processing.</td>
</tr>
<tr>
<td>value</td>
<td>Whether event processing is to occur.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – The event should not be fired.</td>
</tr>
<tr>
<td></td>
<td>No – The event should be fired (default).</td>
</tr>
</tbody>
</table>
CHAPTER 3  DataWindow Object Properties

Usage

In the painter  Select the control and set the value in the Properties view, General tab.

Examples

string setting  
   dw1.Object.b_name.SuppressEventProcessing = "Yes"

   setting =
   dw1.Describe("b_name.SuppressEventProcessing")
   dw1.Modify("b_name.SuppressEventProcessing = 'No'")

Syntax

Description  The complete syntax for the DataWindow.

Applies to  DataWindows

Syntax  PowerBuilder dot notation:

   dw_control.Object.DataWindow.Syntax

Describe argument:

   "DataWindow.Syntax"

Examples

   setting = dw1.Object.DataWindow.Syntax
   setting = dw1.Describe("DataWindow.Syntax")

Syntax.Data

Description  The data in the DataWindow object described in parse format (the format required by the DataWindow parser).

Applies to  DataWindows

Syntax  PowerBuilder dot notation:

   dw_control.Object.DataWindow.Syntax.Data

Describe argument:

   "DataWindow.Syntax.Data"

Usage  Use this property with the Syntax property to obtain the description of the DataWindow object and the data. Using this information, you can create a syntax file that represents both the structure and data of a DataWindow at an instant in time. You can then use the syntax file as a DropDownDataWindow containing redefined data at a single location or to mail this as a text object.
Syntax.Modified

**Description**

Whether the DataWindow syntax has been modified by a function call or user intervention. Calling the Modify, SetSort, or SetFilter method or changing the size of the DataWindow grid automatically sets Syntax.Modified to Yes.

**Applies to**

DataWindows

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Syntax.Modified
```

Describe and Modify argument:

"DataWindow.Syntax.Modified { = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Whether the DataWindow syntax has been modified. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Yes – DataWindow syntax has been modified.</td>
</tr>
<tr>
<td></td>
<td>• No – DataWindow has not been modified.</td>
</tr>
</tbody>
</table>

**Usage**

Use this property in Modify to set Syntax.Modified to No after you cause a change in the syntax that does not affect the user (such as setting preview on).

**Examples**

```
string setting
setting = dw1.Object.DataWindow.Syntax.Modified
dw1.Object.DataWindow.Syntax.Modified = "No"

setting = dw1.Describe("DataWindow.Syntax.Modified")
dw1.Modify("DataWindow.Syntax.Modified=No")
```

---

**Table (for Create)**

**Description**

The section of the DataWindow syntax that specifies information about the DataWindow’s database table, including the name of the update table.

Use Table in DataWindow syntax for the Create method.

**Syntax**

Does not apply.

**Usage**

Use this property to redefine a DataWindow result set. You can add a column, change the datatype of a column, or make other changes to the table section of your DataWindow involving properties that are not accessible through Modify calls or dot notation.
Caution
When you use this property to redefine the result set, you must redefine the table section in its entirety.

You can call the GetItem and SetItem methods to access columns added using this property, but the columns do not display in the DataWindow unless you call Modify("create column(...)") to add them.

To redefine your table section:
1. Export your DataWindow object to a DOS file.
2. Copy only the table section into your script.
3. Modify the table section to meet your needs.
4. Put the new table definition into a string variable. Change existing double quotation marks (") in the string to single quotation marks (') and change the tilde quotation marks to tilde tilde single quotation marks (~~').
5. Call Modify. Modifying the table section of your DataWindow causes the DataWindow to be reset.
6. (Optionally) Call Modify to add the column to the DataWindow display.

Table (for InkPicture and TableBlobs)

Description
The name of the database table that contains the blob(s).

Applies to
InkPicture and TableBlob controls

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Table

Describe and Modify argument:

"controlname.Table { = ' tablename ' }"
Table.property

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control in the DataWindow.</td>
</tr>
<tr>
<td>tablename</td>
<td><em>(exp)</em> A string specifying the name of the table that contains the blob data. Tablename can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage

**In the painter**  Select the control and set the value in the Properties view, Definition tab, Table option. For InkPicture controls, the table contains a large binary column to store ink overlay data and a large binary column to hold a background image for the InkPicture control. For TableBlob controls, the table contains the large binary database object you want to insert into the DataWindow.

Examples

```powershell
setting = dw1.Object.inkpic_1.Table
dw1.Object.inkpic_1.Table = "inkpictable"

setting = dw1.Describe("inkpic_1.Table")
dw1.Modify("inkpic_1.Table='inkpictable'")

setting = dw1.Object.blob_1.Table
dw1.Object.blob_1.Table = "emp_pictures"

setting = dw1.Describe("blob_1.Table")
dw1.Modify("blob_1.Table='emp_pictures'")
```

Table.property

Description

Properties for the DataWindow’s DBMS connection.

You can also specify stored procedures for update activities. For information, see Table.sqlaction.property.

Applies to

DataWindows

Syntax

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.Table.property
```

Describe and Modify argument:

```
"DataWindow.Table.property { = value }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property for the DataWindow’s DBMS connection. Properties and appropriate values are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property.</td>
</tr>
</tbody>
</table>
### Property for Table

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments</td>
<td>(Read only) A string containing retrieval argument names and types for the DataWindow.</td>
</tr>
<tr>
<td>CrosstabData</td>
<td>A string containing a tab-separated list of the expressions used to calculate the values of columns in a crosstab DataWindow.</td>
</tr>
<tr>
<td>Data.Storage</td>
<td>A string indicating whether table data is to be kept in memory or offloaded to disk. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Memory (Default) – Table data is to be kept in memory.</td>
</tr>
<tr>
<td></td>
<td>• Disk – Table data is to be offloaded to disk.</td>
</tr>
<tr>
<td></td>
<td>Painter: Rows&gt;Retrieve Options&gt;Rows to Disk.</td>
</tr>
<tr>
<td>Delete.Argument</td>
<td>(Internal use only) A string containing arguments to pass to the delete method.</td>
</tr>
<tr>
<td>Delete.Method</td>
<td>(Internal use only) The name of the method.</td>
</tr>
<tr>
<td>Delete.Type</td>
<td>(Internal use only) Currently stored procedure is the only type implemented.</td>
</tr>
<tr>
<td>Filter</td>
<td>(exp) A string containing the filter for the DataWindow. Filters are expressions that can evaluate to true or false. The Table.Filter property filters the data before it is retrieved. To filter data already in the DataWindow’s buffers, use the Filter property or the SetFilter and Filter methods. The filter string can be a quoted DataWindow expression. Painter: Rows&gt;Filter.</td>
</tr>
<tr>
<td>GridColumns</td>
<td>(Read-only) The grid columns of a DataWindow.</td>
</tr>
<tr>
<td>Insert.Argument</td>
<td>(Internal use only) A string containing arguments to pass to the insert method.</td>
</tr>
<tr>
<td>Insert.Method</td>
<td>(Internal use only) The name of the method.</td>
</tr>
<tr>
<td>Insert.Type</td>
<td>(Internal use only) Currently stored procedure is the only type implemented.</td>
</tr>
<tr>
<td>Procedure</td>
<td>A string that contains the number of the result set returned by the stored procedure to populate the DataWindow object. You can use this property only if your DBMS supports stored procedures. Use this property to change the stored procedure or to change the data source from a SELECT statement or script to a stored procedure (see the example). Painter: Set when Stored Procedure is selected as a data source.</td>
</tr>
</tbody>
</table>

---

**DataWindow Reference** 379
### Property for Table

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
</table>
| **Select**        | A string containing the SQL SELECT statement that is the data source for the DataWindow. Use this property to specify a new SELECT statement or change the data source from a stored procedure or Script to a SELECT statement. Table.Select has several advantages over the SetSqlSelect method:  
  - It is faster. PowerBuilder does not validate the statement until retrieval.  
  - You can change data source for the DataWindow. For example, you can change from a SELECT to a Stored Procedure.  
  - You can use none or any of the arguments defined for the DataWindow object in the SELECT. You cannot use arguments that were not previously defined for the DataWindow object.  
  Describe always tries to return a SQL SELECT statement. If the database is not connected and the property’s value is a PBSELECT statement, Describe will convert it to a SQL SELECT statement if a SetTransObject method has been executed.  
  If you are using describeless retrieval (the StaticBind database parameter is set to 1), you cannot use the Select property.  
  Painter: Set when Select or Quick Select is selected as a data source. |

<table>
<thead>
<tr>
<th><strong>Select.Attribute</strong></th>
<th>(Read-only) A string containing the PBSELECT statement for the DataWindow.</th>
</tr>
</thead>
</table>
| **Sort**            | (exp) A string containing the sort criteria for the DataWindow, for example, “1A,2D” (column 1 ascending, column 2 descending). The Table.Sort property sorts the data before it is retrieved. To sort data already in the DataWindow’s buffers, use the SetSort and Sort methods.  
  The value for Sort is quoted and can be a DataWindow expression.  
  Painter: Rows>Sort.                                                                                                                   |

<table>
<thead>
<tr>
<th><strong>SQLSelect</strong></th>
<th>The most recently executed SELECT statement. Setting this has no effect. See Select in this table.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Update.Argument</strong></td>
<td>(Internal use only) A string containing arguments to pass to the update method.</td>
</tr>
<tr>
<td><strong>Update.Method</strong></td>
<td>(Internal use only) The name of the method.</td>
</tr>
<tr>
<td><strong>Update.Type</strong></td>
<td>(Internal use only) Currently stored procedure is the only type implemented.</td>
</tr>
</tbody>
</table>
CHAPTER 3 DataWindow Object Properties

### Examples

```plaintext
setting = dw1.Object.DataWindow.Table.Sort

dw1.Object.DataWindow.Table.Data.Storage = "disk"

dw1.Object.DataWindow.Table.Filter = "salary>50000"

setting = dw1.Describe("DataWindow.Table.Sort")

dw1.Modify("DataWindow.Table.Filter='salary>50000'")

sqlvar = 'SELECT ... WHERE ...'

dw1.Modify("DataWindow.Table.Select='" + sqlvar + "'")
```

### Property for Table: UpdateKey InPlace

Whether the key column can be updated in place or the row has to be deleted and reinserted. This value determines the syntax PowerBuilder generates when a user modifies a key field:

- **Yes** – Use the `UPDATE` statement when the key is changed so that the key is updated in place.
- **No** – Use a `DELETE` and an `INSERT` statement when the key is changed.

**Caution**

When there are multiple rows in a DataWindow object and the user switches keys or rows, updating in place might fail due to DBMS duplicate restrictions.

**Painter:** Rows>Update Properties, Key Modification.

### Property for Table: UpdateTable

A string specifying the name of the database table used to build the Update syntax.

**Painter:** Rows>Update Properties, Table to Update.

### Property for Table: UpdateWhere

An integer indicating which columns will be included in the `WHERE` clause of the `Update` statement. The value of `UpdateWhere` can impact performance or cause lost data when more than one user accesses the same tables at the same time.

Values are:

- **0** – Key columns only (risk of overwriting another user’s changes, but fast).
- **1** – Key columns and all updatable columns (risk of preventing valid updates; slow because `SELECT` statement is longer).
- **2** – Key and modified columns (allows more valid updates than 1 and is faster, but not as fast as 0).

For more about the effects of this setting, see the discussion of the Specify Update Characteristics dialog box in the *Users Guide*.

**Painter:** Rows>Update Properties, Where Clause for Update/Delete.
Table.sqlaction.property

Table.sqlaction.property

Description
The way data is updated in the database. When the Update method is executed, it can send UPDATE, INSERT, and DELETE SQL statements to the DBMS. You can specify that a stored procedure be used instead of the default SQL statement for each type of data modification.

Applies to
DataWindows

Syntax
PowerBuilder dot notation:

dw_control.Object.DataWindow.Table.sqlaction.property

Describe and Modify argument:
"DataWindow.Table.sqlaction.property { = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqlaction</td>
<td>The SQL statement that would ordinarily be executed as part of a database update. Values are: • UPDATE • INSERT • DELETE</td>
</tr>
<tr>
<td>property</td>
<td>A property for sqlaction. Properties and appropriate values are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td>The value to be assigned to the property.</td>
</tr>
</tbody>
</table>

Property for Table

Value

Arguments
A string specifying the arguments used in the stored procedure. The string takes this format:

("argname", valuetype { =("valuesrc", datasrc, paramtype) })

Argname is the name of the stored procedure parameter.
Valuetype is one of the keywords described below. Datasrc and paramtype apply to the COLUMN keyword.
Valuesrc is the column, computed field, or expression that produces the value to be passed to the stored procedure.

Method
A string specifying the name of the stored procedure. The stored procedure is used only if the value of Type is SP.

Type
Specifies whether the database update is performed using a stored procedure. Values are:
• SP – The update is performed using a stored procedure.
• SQL – The update is performed using standard SQL syntax (default).
CHAPTER 3  DataWindow Object Properties

<table>
<thead>
<tr>
<th>Keyword for valuetype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMN</td>
<td>The argument value will be taken from the table and column named in valuesrc. Valuesrc has the form: &quot;tablename.column&quot; For COLUMN, you must also specify whether the data is the new or original column value. Values for datasrc are:</td>
</tr>
<tr>
<td></td>
<td>• NEW  The new column value that is being sent to the database.</td>
</tr>
<tr>
<td></td>
<td>• ORIG  The value that the DataWindow originally read from the database.</td>
</tr>
<tr>
<td></td>
<td>You can also specify the type of stored procedure parameter. Values for paramtype are:</td>
</tr>
<tr>
<td></td>
<td>• IN  (Default) An input parameter for the procedure.</td>
</tr>
<tr>
<td></td>
<td>• OUT  An output parameter for the procedure. The DataWindow will assign the resulting value to the current row and column (usually used for identity and timestamp columns).</td>
</tr>
<tr>
<td></td>
<td>• INOUT An input and output parameter.</td>
</tr>
<tr>
<td></td>
<td>A sample string for providing a column argument is:</td>
</tr>
<tr>
<td></td>
<td>(&quot;empid&quot;, COLUMN=&quot;employee.empid&quot;, ORIG, IN))</td>
</tr>
<tr>
<td>COMPUTE</td>
<td>The computed field named in valuesrc is the source of the value passed to the stored procedure.</td>
</tr>
<tr>
<td></td>
<td>A sample string for providing a computed field argument is:</td>
</tr>
<tr>
<td></td>
<td>(&quot;newsalary&quot;, COMPUTE=&quot;salary_calc&quot;)</td>
</tr>
<tr>
<td>EXPRESSION</td>
<td>The expression specified in valuesrc is evaluated and passed to the stored procedure.</td>
</tr>
<tr>
<td></td>
<td>A sample string for providing an expression argument is:</td>
</tr>
<tr>
<td></td>
<td>(&quot;dept_name&quot;, EXPRESSION=&quot;LookUpDisplay(dept_id)&quot;)</td>
</tr>
<tr>
<td>UNUSED</td>
<td>No value is passed to the stored procedure.</td>
</tr>
</tbody>
</table>

Usage

**In the painter**  Set the values using Rows>Stored Procedure Update. Select the tab page for the SQL command you want to associate with a stored procedure.

**In code**  If you enable a DataWindow object to use stored procedures to update the database when it is not already using stored procedures, you must change Type to SP first. Setting Type ensures that internal structures are built before you set Method and Arguments. If you do not change Type to SP, then setting Method or Arguments will fail.
When the values you specify in code are nested in a longer string, you must use the appropriate escape characters for quotation marks.

Examples

Each is all on one line:

```powerbuilder
dw_x.Describe("DataWindow.Table.Delete.Method")
dw_x.Describe("DataWindow.Table.Delete.Arguments")
dw_x.Modify("DataWindow.Table.Delete.Type=SP")
dw_x.Modify("DataWindow.Table.Delete.Arguments=(("id-", COLUMN=(-"department.dept_id!-", ORIG)))")
dw_x.Modify("DataWindow.Table.Delete.Method=~-"spname-"~")
```

---

**TabSequence**

**Description**

The number assigned to the specified control in the DataWindow’s tab order. You can also call the SetTabOrder method to change TabSequence.

**Applies to**

Column controls

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.columnname.TabSequence
```

Describe and Modify argument:

```
"columnname.TabSequence { = number }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The name of the column whose tab order you want to get or set.</td>
</tr>
<tr>
<td>number</td>
<td>A number from 0 to 32000 specifying the position of the column in the tab order. A value of 0 takes the column out of the tab order and makes it read-only.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter** Set the value using Format>Tab Order.

**Tab order changes have no effect in grid DataWindow objects**

In a grid DataWindow object, the tab sequence is always left to right (except on right-to-left operating systems). Changing the tab value to any number other than 0 has no effect.

**Examples**

```powerbuilder
string setting
setting = dw1.Object.emp_name.TabSequence
dw1.Object.emp_name.TabSequence = 10
```
setting = dw1.Describe("emp_name.TabSequence")
dw1.Modify("emp_name.TabSequence = 10")

**Tag**

**Description**
The tag value of the specified control. The tag value can be any text you see fit to use in your application.

**Applies to**
Button, Column, Computed Field, Graph, GroupBox, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.controlname.Tag
```

Describe and Modify argument:

```
"controlname.Tag { = ' string '}
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of a control in the DataWindow.</td>
</tr>
<tr>
<td>string</td>
<td><em>(exp)</em> A string specifying the tag for controlname. String is quoted and</td>
</tr>
<tr>
<td></td>
<td>can be a DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter** Select the control and set the value in the Properties view, General tab, Tag option.

**Examples**

```
setting = dw1.Object.blob_1.Tag
dw1.Object.graph_1.Tag = 'Graph of results'
setting = dw1.Describe("blob_1.Tag")
dw1.Modify("graph_1.Tag = 'Graph of results'")
```

**Target**

**Description**
The columns and expressions whose data is transferred from the DataWindow to the OLE object.

**Applies to** OLE Object controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.oleobjectname.Target
```

Describe and Modify argument:

```
"oleobjectname.Target { = 'columnlist '}
```

### Template

**Parameter** | **Description**
--- | ---
*oleobjectname* | The name of the OLE Object control for which you want to get or set the data to be transferred.

*columnlist* | (*exp*) A list of the columns or expressions whose data is transferred to the OLE object. If there is more than one, separate them with commas. *Columnlist* can be a quoted DataWindow expression.

**Usage**

GroupBy and Range also affect the data that is transferred to the OLE object.

**In the painter**
Select the control and set the value in the Properties view, Data tab, Target Data option.

**Examples**

```powershell
setting = dw1.Object.ole_1.Target
dw1.Object.ole_1.Target = 'lname, Len(companyname)'

setting = dw1.Describe("ole_1.Target")
dw1.Modify("ole_1.Target = 'lname, Len(companyname)'")
```

### Template

**Description**

The name of a file that will be used to start the application in OLE.

**Applies to**

TableBlob controls

**Syntax**

PowerBuilder dot notation:

`dw_control.Object.tblobname.Template`

Describe and Modify argument:

"*tblobname*.Template { = 'string' }"

**Parameter** | **Description**
--- | ---
*tblobname* | The name of a TableBlob control in the DataWindow.

*string* | (*exp*) A string whose value is the file name of an application that is to be the OLE template. *String* is quoted and can be a DataWindow expression.

**Usage**

**In the painter**
Select the control and set the value in the Properties view, Definition tab, File Template option.

**Examples**

```powershell
setting = dw1.Object.blob_1.Template
dw1.Object.blob_1.Template='Excel.xls'

setting = dw1.Describe("blob_1.Template")
dw1.Modify("blob_1.Template='Excel.xls'")
```
CHAPTER 3  DataWindow Object Properties

Text
Description  The text of the specified control.
Applies to  Button, GroupBox, and Text controls
Syntax  PowerBuilder dot notation:
        \texttt{dw\_control.Object.textname.Text}
Describe and Modify argument:
        \texttt{"textname.Text \{ = \text{string} \}\}"

Usage  In the painter  Select the control and set the value in the Properties view,
        General tab, Text option.
Examples  
        \texttt{setting = dw1.Object.text\_1.Text}
        \texttt{dw1.Object.text\_1.Text = \text{"Employee &Name"}}
        \texttt{setting = dw1.Describe("text\_1.Text")}
        \texttt{dw1.Modify("text\_1.Text='Employee &Name'")}

Timer\_Interval
Description  The number of milliseconds between the internal timer events. When you use
        time in a DataWindow, an internal timer event is triggered at the interval
        specified by Timer\_Interval. This determines how often time fields are
        updated.
Applies to  DataWindows
Syntax  PowerBuilder dot notation:
        \texttt{dw\_control.Object.DataWindow.Timer\_Interval}
Describe and Modify argument:
        \texttt{"DataWindow.Timer\_Interval \{ = \text{number} \}"}
SyntaxFromSql:
        \texttt{DataWindow ( Timer\_Interval = \text{number} )}
Title

Description
The title of the graph.

Applies to
Graph controls

Syntax
PowerBuilder dot notation:

```
dw_control.Object.graphname.Title
```

Describe and Modify argument:

```
"graphname.Title { = 'titlestring' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphname</td>
<td>In the DataWindow object, the name of the Graph control for which you want to get or set the title</td>
</tr>
<tr>
<td>titlestring</td>
<td>A string specifying the graph’s title</td>
</tr>
</tbody>
</table>

Usage

**In the painter** Select the control and set the value in the Properties view, General tab, Title option.

The default expression for the TitleDispAttr.DisplayExpression property is "title", which refers to the value of the Title property. The display expression can combine the fixed text of the Title property with other text, functions, and operators. If the expression for TitleDispAttr.DisplayExpression does not include the Title property, then the value of the Title property will be ignored.

For an example, see DispAttr.fontproperty.
Examples

\[
\begin{align*}
\text{setting} &= \text{dw1.Object.gr_1.Title} \\
\text{dw1.Object.gr_1.Title} &= 'Sales Graph' \\
\text{setting} &= \text{dw1.Describe("gr_1.Title")} \\
\text{dw1.Modify("gr_1.Title = 'Sales Graph'"})
\end{align*}
\]

(title).DispAttr.fontproperty

See DispAttr.fontproperty.

Tooltip.property

Description
Settings for tooltips for a column or control.

Applies to
Button, Column, Computed Field, Graph, GroupBox, InkPicture, Line, OLE, Blob OLE, Oval, Picture, Rectangle, Report, RoundRectangle, and Text controls

Syntax
PowerBuilder dot notation:

\[
dw_{\text{control}}.Object.\text{controlname}.\text{Tooltip.property}
\]

Describe and Modify argument:

\[
"\text{controlname}.\text{Tooltip.property} \{ = 'value' \}"
\]

SyntaxFromSql:

\[
\begin{align*}
\text{Column} ( \text{Tooltip.property} &= \text{value} ) \\
\text{Text} ( \text{Tooltip.property} &= \text{value} )
\end{align*}
\]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The control whose Tooltip properties you want to get or set. When generating DataWindow syntax with SyntaxFromSql, the Tooltip settings apply to all columns or all text controls.</td>
</tr>
<tr>
<td>property</td>
<td>A property that applies to the tooltip of a control, as listed in the Property table below.</td>
</tr>
<tr>
<td>value</td>
<td>Values for the properties are shown below. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property for Tooltip</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backcolor</td>
<td>(exp) A long specifying the color (the red, green, and blue values) to be used for the background color of the tooltip box.</td>
</tr>
<tr>
<td>Delay.initial</td>
<td>(exp) An integer specifying the time in milliseconds before the tooltip box displays (minimum zero, maximum 32767). Default value is 0.</td>
</tr>
</tbody>
</table>
**Tooltip.property**

<table>
<thead>
<tr>
<th>Property for Tooltip</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delay.visible</td>
<td>(exp) An integer specifying the time in milliseconds that the tooltip box remains visible (minimum zero, maximum 32767). Default value is 32000.</td>
</tr>
<tr>
<td>Enabled</td>
<td>(exp) Whether the tooltip is enabled. Values are: Yes – The tooltip is enabled. No – (Default) The tooltip is disabled.</td>
</tr>
<tr>
<td>Icon</td>
<td>(exp) A string for the icon to display to the left of the title in the tooltip box. The default is for no icon to display. Three stock icons are available for display in the tooltip box: Info, Warning, and Error. 0 – None 1 – Info 2 – Warning 3 – Error</td>
</tr>
<tr>
<td>Isbubble</td>
<td>(exp) Whether the tooltip box displays as a basic rectangle or a callout bubble. Values are: 0 – Displays the standard tooltip shape. 1 – Displays the tooltip as a rounded callout bubble.</td>
</tr>
<tr>
<td>Tip</td>
<td>(exp) A string specifying the text for the tooltip. If you use an expression, make sure the result is converted to a string.</td>
</tr>
<tr>
<td>Title</td>
<td>(exp) A string specifying the tooltip box title. If you use an expression, make sure the result is converted to a string.</td>
</tr>
<tr>
<td>Textcolor</td>
<td>(exp) A long expression specifying the color (the red, green, and blue values) to be used as the control’s tooltip color.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter** Select the control and set the value on the Tooltip tab of the Properties view.

Not available for columns or controls in RichText, Graph, or OLE DataWindow objects, and not supported in Web Forms targets. If you want to add a tooltip to an InkPicture in a DataWindow, that InkPicture must not be enabled.

**Examples**

```
dw_1.Object.oval_1.Tooltip.Color = RGB(255, 0, 128)
dw_1.Modify("emp_name.Tooltip.Color='11665407'")
SQLCA.SyntaxFromSQL(sql_syntax, & "Style(...) Column(Tooltip.Delay.Visible=15 ...) & ...", ls_Errors)
SQLCA.SyntaxFromSQL(sqlSyntax, & "Style(...) Column(Tooltip.TextColor=11665407 ...)" & , ls_Errors)
```
**Trail_Footer**

Description: Whether the footer of a nested report is displayed at the end of the report or at the bottom of the page. Trail_Footer applies only to reports in a composite DataWindow. Setting Trail_Footer to No forces controls following the report onto a new page.

Applies to: Report controls

Syntax: PowerBuilder dot notation:

```
dw_control.Object.reportname.Trail_Footer
```

Describe and Modify argument:

```
"reportname.Trail_Footer { = value }"
```

**Parameter** | **Description**
---|---
`reportname` | The name of the report control for which you want to get or set Trail_Footer.
`value` | Whether the report’s footer trails the last line of the report or appears at the bottom of the page. Values are:
- Yes – The footer appears right after the last line of data in the report.
- No – The footer appears at the bottom of the page, forcing any data following the report onto the following page.

Examples:

```
string setting
setting = dw1.Object.rpt_1.Trail_Footer
dw1.Object.rpt_1.Trail_Footer = "Yes"

setting = dw1.Describe("rpt_1.Trail_Footer")
dw1.Modify("rpt_1.Trail_Footer = Yes")
```

**Trailer.#.property**

See Bandname.property.

**Transparency (columns and controls)**

Description: Settings for the transparency of the text in a control.

Applies to: Button, Column,Computed Field, GroupBox, and Text controls
Transparency (picture controls in DataWindows)

Syntax

PowerBuilder dot notation:

\[ dw\_control.\text{Object.}\text{controlname}.\text{Transparency} \]

Describe and Modify argument:

\[ "\text{controlname}.\text{Transparency} \{ = ' value ' \}" \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the column or control in the DataWindow for which you want to specify the percentage transparency for the text of the column or control.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) An integer in the range 0 to 100, where 0 means that the text background is opaque and 100 that it is completely transparent.</td>
</tr>
</tbody>
</table>

Usage

In the painter Select the control and set the value in the Font tab of the Properties view.

Using Transparency with fonts

The Transparency property works with all fonts, but only on screen. Text with transparent properties appears blurry in PDF files. The transparent text does not display in print unless you use True Type fonts.

Examples

setting = dw_1.Object.cb_1.Transparency

dw_1.Object.cb_1.Transparency = 50

Transparency (picture controls in DataWindows)

Description

Settings for the transparency of a picture control. This feature is not supported in the RichText and OLE processing styles. WebForms are also not supported.

Applies to

Picture controls

Syntax

PowerBuilder dot notation:

\[ dw\_control.\text{Object.}\text{controlname}.\text{Transparency} \]

Describe and Modify argument:

\[ "\text{controlname}.\text{Transparency} \{ = ' value ' \}" \]

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the picture control in the DataWindow for which you want to specify the percentage transparency.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) An integer in the range 0 to 100, where 0 means that the picture is opaque and 100 that it is completely transparent.</td>
</tr>
</tbody>
</table>
Usage

**In the painter**  Select the control and set the value in the General tab of the Properties view.

Examples

\[ \text{dw}_1\text{.Object.p}_1\text{.Transparency} = 50 \]

**Transparency (DataWindow objects)**

**Description**  Setting that controls the transparency of the background/primary gradient color.

**Applies to**  DataWindows

**Syntax**  PowerBuilder dot notation:

\[ \text{dw}_\text{control}.\text{transparency} \]

Describe and Modify argument:

"DataWindow (transparency = \{ integer \})"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>An integer in the range 0 to 100, where 0 means that the primary color (background) is opaque and 100 that it is completely transparent.</td>
</tr>
</tbody>
</table>

Usage

**In the painter**  Select the DataWindow object and set the value on the Background tab of the Properties view.

If you save to an EMF or WMF, the properties on the Background tab are not saved with the DataWindow.

See also

Brushmode
Color

**Tree.property**

**Description**  Settings for a TreeView DataWindow.

**Applies to**  TreeView DataWindows

**Syntax**  PowerBuilder dot notation:

\[ \text{dw}_\text{control}.\text{Object.DataWindow.Tree.property} \]

Describe and Modify argument:

"DataWindow.Tree.property \{ = value \} "

DataWindow Reference 393
**Tree.property**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>A property that controls the appearance or behavior of the TreeView DataWindow. Properties and their settings are listed in the table below.</td>
</tr>
<tr>
<td>value</td>
<td><em>(exp)</em> A string value for the file name of the tree node icon in the detail band. <em>Value</em> can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

### Property for Tree

<table>
<thead>
<tr>
<th>Property for Tree</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultExpandToLevel</td>
<td>A long value that is the default level of expansion for the TreeView DataWindow. For example, if the default level is 2, only data with a level less than or equal to 2 is expanded by default. The value must represent a valid level. Painter: Expand To Level By Default drop-down list on the General page in the Properties view. The list displays the levels that have been created for the DataWindow.</td>
</tr>
<tr>
<td>Indent</td>
<td>A long value in the units specified for the DataWindow that defines the position of the state icon. The state icon is a plus (+) or minus (-) sign that indicates whether the tree node is in a collapsed or expanded state. The icon’s indent indicates the level of the node in the tree. The X position of the state icon is the X position of its parent plus value. Painter: Select or enter a value in the Indent Value box on the General page.</td>
</tr>
<tr>
<td>SelectNodeByMouse</td>
<td>A boolean value that indicates whether you can select a tree node by clicking the node with the mouse. Values are: Yes – You can select a tree node with a mouse-click (default). No – You cannot select a tree node with a mouse-click. Painter: Node By Mouse check box.</td>
</tr>
<tr>
<td>ShowConnectLines</td>
<td>A boolean value that indicates whether lines connecting parents and children display in the DataWindow object. This property is not supported by the Web DataWindow. If you want to show lines connecting rows in the detail band to their parent, you must also set ShowLeafNodeConnectLines. Values are: Yes – Display connecting lines (default). No – Do not display connecting lines. Painter: Show Lines check box.</td>
</tr>
</tbody>
</table>
CHAPTER 3  DataWindow Object Properties

### Property for Tree

<table>
<thead>
<tr>
<th>Property for Tree</th>
<th>Value</th>
</tr>
</thead>
</table>
| ShowLeafNodeConnectLines | A boolean value that indicates whether lines connecting rows in the detail band to their parent display in the DataWindow object. This property is disabled if Show Lines box is not set. This property is not supported by the Web DataWindow.  
Values are:  
- Yes – Display connecting lines (default).  
- No – Do not display connecting lines.  
Painter: Connect Leaf Nodes check box. |
| ShowTreeNodeIcon | A boolean value that indicates whether tree node icons for level and detail bands display. If this property is not set, the Expanded and Collapsed Tree Node Icon File properties on the General properties page for each TreeView level are disabled.  
Values are:  
- No – Do not display tree node icons (default).  
- Yes – Display tree node icons.  
Painter: Use Tree Node Icon check box. |
| StateIconAlignMode | A long value that indicates how the state icon is aligned vertically with respect to the TreeView level band.  
Values are:  
- 0 – Middle (default).  
- 1 – Top.  
- 2 – Bottom.  
Painter: State Icon Align Mode drop-down list. |

### Usage

**In the painter**  Select the control and set values in the Properties view, General tab.

### Examples

The following code sets and gets the long value that determines how many levels of the TreeView are expanded by default:

```pseudo
long ll_expandlevel
dw1.Object.datawindow.tree.DefaultExpandToLevel = 1
ll_expandlevel = &
dw1.Object.DataWindow.Tree.DefaultExpandToLevel
```

The following code gets and sets the Indent value:

```pseudo
indentVal = dw1.Object.DataWindow.Tree.indent
dw1.Object.DataWindow.Tree.indent = 80
```

The following examples manipulate the SelectNodeByMouse property:

```pseudo
if cbx_selectnodebymouse.checked then
    ls_selectnodebymouse='yes'
```
else
    ls_selectnodebymouse='no'
end if
ls_ret=dw1.modify("datawindow.tree.selectnodebymouse='" +ls_selectnodebymouse+"'")

if len(ls_ret)>0 then Messagebox("",ls_ret)
end if
ls_selectnodebymouse=dw1.Describe("datawindow.tree.
selectnodebymouse")
if lower(ls_selectnodebymouse)='no' then
cbx_selectnodebymouse.checked=false
else
    cbx_selectnodebymouse.checked=true
end if
dw1.modify("datawindow.tree.selectnodebymouse='yes'")
dw1.Describe("datawindow.tree.selectnodebymouse")

The following examples manipulate the show connecting lines properties:

boolean lb_ShowLines, lb_ShowLeafLines
lb_ShowLines = &
dw1.Object.DataWindow.Tree.ShowConnectLines
dw1.Object.DataWindow.Tree.ShowConnectLines='yes'
ShowLeafNodeConnectLines
dw1.Object.DataWindow.Tree.ShowLeafNodeConnectLines =&
'yes'

The following example gets the current value of the StateIconAlignMode
property and sets it to be aligned at the top:

ls_StateIconAlignMode =
dw1.Object.DataWindow.Tree.StateIconAlignMode
//Align Top
dw1.Object.DataWindow.Tree.StateIconAlignMode = 1

---

**Tree.Leaf.TreeNodeIconName**

**Description**: The file name of the tree node icon in the detail band.

**Applies to**: TreeView DataWindows

**Syntax**: PowerBuilder dot notation:

```
  dw_control.Object.DataWindow.Tree.Leaf.TreeNodeIconName
```
Describe and Modify argument:

"DataWindow.Tree.Leaf.TreeNodeIconName
{ = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td><em>(exp)</em> A string value for the file name of the tree node icon in the detail band. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

Usage

**In the painter** Select the detail band by clicking the gray divider for the band. Specify a file name and location in the Tree Node Icon File box on the General tab in the Properties view. This property is disabled if Use Tree Node Icon is not set on the General tab in the Properties view for the DataWindow.

For the TreeView Web DataWindow, the image file must be deployed to the Web site.

**Examples**

```
ls_LeafIcon = &
dwl.Object.DataWindow.Tree.Leaf.TreeNodeIconName

dwl.Object.DataWindow.Tree.Leaf.TreeNodeIconName = &
"c:\pictures\treenode.bmp"
```

**Tree.Level.#.property**

**Description**
The file name of the icon for a TreeView node in a TreeView level band when the icon is in either the expanded or collapsed state. You set the icon file name separately for each TreeView level band.

**Applies to**
TreeView DataWindows

**Syntax**
Describe and Modify argument:

"DataWindow.Tree.Level.#.property
{ = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#</td>
<td>The number of the level for which you want to specify an icon. The level number must exist.</td>
</tr>
<tr>
<td>property</td>
<td>A property that indicates whether the icon specified is for the expanded or collapsed state. Values are:</td>
</tr>
<tr>
<td></td>
<td>• CollapsedTreeIconName</td>
</tr>
<tr>
<td></td>
<td>• ExpandedTreeIconName</td>
</tr>
<tr>
<td>value</td>
<td><em>(exp)</em> A string value that is the file name of the tree node icon in the selected TreeView level band. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>
### Type

**Usage**

**In the painter**  Select the level by clicking the gray divider for the band. Specify a file name and location in the Collapsed Tree Node Icon File and Expanded Tree Node Icon File boxes on the General tab in the Properties view for the band. These properties are disabled if Use Tree Node Icon is not selected on the General tab in the Properties view for the DataWindow.

You cannot get or set these properties using dot notation.

For a TreeView Web DataWindow, the image files must be deployed to the Web site.

**Examples**

The following example gets the name of the icon used when a level 1 node is collapsed:

```
string ls_ico
ls_ico = dw_tview.Describe &
("DataWindow.Tree.Level.1.CollapsedTreeNodeIconName")
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Syntax</th>
</tr>
</thead>
</table>
|      | The type of the control (for Describe) or the type of presentation style (for SyntaxFromSql). | PowerBuilder dot notation:  
```
dw_control.Object.controlname.Type
```

Describe argument:  
```
"controlname.Type"
```
### Parameter: controlName

The name of the control for which you want the type. Valid values are:
- datawindow
- bitmap (for Picture)
- button
- column
- compute (for Computed Field)
- graph
- groupbox
- line
- ole
- ellipse (for Oval)
- rectangle
- report
- roundrectangle
- tableblob
- text

#### SyntaxFromSql:

Style (Type = value)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>A keyword specifying the presentation style for the DataWindow object. Keywords are: (Default) Tabular, Grid, Form (for the Freeform style), Crosstab, Graph, Group, Label, Nested, Ole, RichText</td>
</tr>
</tbody>
</table>

#### Examples

```plaintext
string setting
setting = dw1.Object.emp_name.Type
setting = dw1.Describe("emp_name.Type")
SQLCA.SyntaxFromSQL(sqlstring, &'Style(... Type=grid ...)', errstring)
```
Units

Description
The unit of measure used to specify measurements in the DataWindow object. You set this in the DataWindow Style dialog box when you define the DataWindow object.

Applies to
DataWindows

Syntax
PowerBuilder dot notation:

dw_control.Object.DataWindow.Units

Describe argument:
"DataWindow.Units"

SyntaxFromSql:

DataWindow ( Units = value )

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The type of units for measurements in the DataWindow. Values are: 0 – PowerBuilder units 1 – Display pixels 2 – 1/1000 of a logical inch 3 – 1/10000 of a logical centimeter</td>
</tr>
</tbody>
</table>

Usage
PowerBuilder units and display pixels are adjusted for printing.

In the painter  Select the DataWindow by deselecting all controls; then set the value in the Properties view, General tab, Units option.

Examples

string setting

setting = dw1.Object.DataWindow.Units

setting = dw1.Describe("DataWindow.Units")

Update

Description
Whether the specified column is updatable. Each updatable column is included in the SQL statement that the Update method sends to the database. All updatable columns should be in the same database table.

Applies to
Column controls

Syntax
PowerBuilder dot notation:

dw_control.Object.columnname.Update

400
Describe and Modify argument:

"columnname.Update { = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>The column for which you want to get or set the updatable status</td>
</tr>
<tr>
<td>value</td>
<td>Whether the column is updatable.</td>
</tr>
<tr>
<td></td>
<td>Values are:</td>
</tr>
<tr>
<td></td>
<td>Yes – Include the column in the SQL statement for updating the database.</td>
</tr>
<tr>
<td></td>
<td>No – Do not include the column in the SQL statement.</td>
</tr>
</tbody>
</table>

Usage

**In the painter** Set the value using Rows>Update Properties, Updateable Columns option.

Examples

```plaintext
string setting
setting = dw1.Object.emp_name.Update
dw1.Object.emp_name.Update = "No"
setting = dw1.Describe("emp_name.Update")
dw1.Modify("emp_name.Update=No")
```

**Validation**

Description

The validation expression for the specified column. Validation expressions are expressions that evaluate to true or false. They provide checking of data that the user enters in the DataWindow.

To set the validation expression, you can also use the SetValidate method. To check the current validation expression, use the GetValidate method.

Applies to Column controls

Syntax PowerBuilder dot notation:

```
dw_control.Object.columnname.Validation
```

Describe and Modify argument:

"columnname.Validation { = 'validationstring' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname</td>
<td>(exp) A string containing the rule that will be used to validate data entered in the column. Validation rules are expressions that evaluate to true or false. Validationstring is quoted and can be a DataWindow expression.</td>
</tr>
<tr>
<td>validationstring</td>
<td>(exp) A string containing the rule that will be used to validate data entered in the column. Validation rules are expressions that evaluate to true or false. Validationstring is quoted and can be a DataWindow expression.</td>
</tr>
</tbody>
</table>
**ValidationMsg**

**Usage**

**In the painter**  Set the value using the Column Specifications view, Validation Expression option. Use operators, functions, and columns to build an expression. Use Verify to test it.

**Examples**

```
string setting
setting = dw1.Object.emp_status.Validation
setting = dw1.Describe("emp_status.Validation")
```

---

**ValidationMsg**

**Description**
The message that PowerBuilder displays instead of the default message when an ItemError event occurs in the column.

**Applies to**
Column controls

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.columnname.ValidationMsg
```

Describe and Modify argument:

```
"columnname.ValidationMsg { = 'string' }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The column for which you want to get or set the error message displayed when validation fails.</td>
</tr>
<tr>
<td><code>string</code></td>
<td><em>(exp)</em> A string specifying the error message you want to set. <em>String</em> is quoted and can be a DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  Set the value using the Column Specifications view, Validation Message option.

**Examples**

```
string setting
setting = dw1.Object.emp_salary.ValidationMsg
dw1.Object.emp_salary.ValidationMsg = & "Salary must be between 10,000 and 100,000"
setting = dw1.Describe("emp_salary.ValidationMsg")
dw1.Modify("emp_salary.ValidationMsg = " & "'Salary must be between 10,000 and 100,000'")
```
Values (for columns)

Description: The values in the code table for the column.

Applies to: Column controls

Syntax: PowerBuilder dot notation:

```powerbuilder
dw_control.Object.columnname.Values
```

Describe and Modify argument:

```powerbuilder
"columnname.Values { = 'string' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The column for which you want to specify the contents of the code table.</td>
</tr>
</tbody>
</table>
| `string`       | (exp) A string containing the code table values for the column. In the string, separate the display values and the actual values with a tab character, and separate multiple pairs of values with a slash using this format:

```plaintext
"displayval~tactualval/displayval~tactualval/ ..."
```

For example:

```plaintext
"red~t1/white~t2"
```

String is quoted and can be a DataWindow expression.

Usage: **In the painter** Select the control and set the value in the Properties view, Edit tab.

When Style Type is DropDownListBox, fill in the Display Value and Data Value columns for the code table.

When Style is Edit or EditMask, select the Use Code Table or Code Table check box and fill in the Display Value and Data Value columns for the code table.

Examples

```powerbuilder
setting = dw1.Object.emp_status.Values
dw1.Object.emp_status.Values = &
  "Active~tA/Part Time~tP/Terminated~tT"
setting = dw1.Describe("emp_status.Values")
dw1.Modify("emp_status.Values =
  'Active~tA/Part Time~tP/Terminated~tT'")
```

Values (for graphs)

See Axis, Axis.property, and DispAttr.fontproperty.
**Vertical_Size**

Description: The height of the columns in the detail area of the DataWindow object. Vertical_Size is meaningful only when Type is Form (meaning the Freeform style). When a column reaches the specified height, PowerBuilder starts a new column to the right of the current column. The space between columns is specified in the Vertical_Spread property.

Applies to: Style keywords

Syntax: SyntaxFromSql:

```sql
Style ( Vertical_Size = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the height of the columns in the detail area of the DataWindow object area in the units specified for the DataWindow</td>
</tr>
</tbody>
</table>

Examples:

```sql
SQLCA.SyntaxFromSQL(sqlstring, &
'Style(... Vertical_Size=1225...)', errstring)
```

**Vertical_Spread**

Description: The vertical space between columns in the detail area of the DataWindow object. Vertical_Spread is meaningful only when Type is Form (meaning the Freeform style). The Vertical_Size property determines when to start a new column.

Applies to: Style keywords

Syntax: SyntaxFromSql:

```sql
Style ( Vertical_Spread = value )
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the vertical space between columns in the detail area of the DataWindow object area in the units specified for the DataWindow</td>
</tr>
</tbody>
</table>

Examples:

```sql
SQLCA.SyntaxFromSQL(sqlstring, &
'Style(... Vertical_Spread=25...)', errstring)
```
**VerticalScrollMaximum**

**Description**

The maximum height of the scroll box of the DataWindow’s vertical scroll bar. This value is set by PowerBuilder based on the content of the DataWindow. Use VerticalScrollMaximum with VerticalScrollPosition to synchronize vertical scrolling in multiple DataWindow objects. The value is a long.

<table>
<thead>
<tr>
<th>Applies to</th>
<th>DataWindows</th>
</tr>
</thead>
</table>

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.VerticalScrollMaximum
```

Describe argument:

"DataWindow.VerticalScrollMaximum"

**Examples**

```java
string setting
setting = dw1.Object.DataWindow.VerticalScrollMaximum
setting = dw1.Describe("DataWindow.VerticalScrollMaximum")
```

**VerticalScrollPosition**

**Description**

The position of the scroll box in the vertical scroll bar. Use VerticalScrollMaximum with VerticalScrollPosition to synchronize vertical scrolling in multiple DataWindow objects.

<table>
<thead>
<tr>
<th>Applies to</th>
<th>DataWindows</th>
</tr>
</thead>
</table>

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.VerticalScrollPosition
```

Describe and Modify argument:

"DataWindow.VerticalScrollPosition{=scrollvalue}"

**Parameter** | **Description**
---|---
`scrollvalue` | A long specifying the position of the scroll box in the vertical scroll bar of the DataWindow

**Examples**

```java
string spos1
spos1 = dw1.Object.DataWindow.VerticalScrollPosition

string spos1, smax, sscroll, modstring
spos1 = &
    dw1.Describe("DataWindow.VerticalScrollPosition")
smax = &
    dw1.Describe("DataWindow.VerticalScrollMaximum")
```
Visible

Description
Whether the specified control in the DataWindow is visible.

Applies to
Button, Column, Computed Field, Graph, GroupBox, Line, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls.

Syntax
PowerBuilder dot notation:

dw_control.Object.controlname.Visible

Describe and Modify argument:
"controlname.Visible { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control for which you want to get or set the Visible property.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) Whether the specified control is visible.</td>
</tr>
<tr>
<td>Values are:</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>False; the control is not visible.</td>
</tr>
<tr>
<td>1</td>
<td>True; the control is visible.</td>
</tr>
<tr>
<td>Value can be a quoted DataWindow expression.</td>
<td></td>
</tr>
</tbody>
</table>

Usage
In the painter  Select the control and set the value in the Properties view, General tab. The Visible property is not supported for column controls in DataWindow objects with the Label presentation style.

Examples

```
string setting
setting = dw1.Object.emp_status.Visible

`dw1.Object.emp_status.Visible = 0`

`dw1.Object.emp_stat.Visible="0-tIf(emp_class=1,0,1)"

setting = dw1.Describe("emp_status.Visible")

`dw1.Modify("emp_status.Visible=0")`

`dw1.Modify("emp_stat.Visible='0~tIf(emp_cls=1,0,1)'")`
```
VTextAlign

Description The way text in a button is vertically aligned.
Applies to Button controls
Syntax PowerBuilder dot notation:

\[ dw\_control\.Object\.buttonname\.VTextAlign \]

Describe and Modify argument:

\[ "buttonname\.VTextAlign \{ = ' value ' \}" \]

Parameter | Description
--- | ---
buttonname | The name of the button for which you want to align text.
value | An integer indicating how the button text is horizontally aligned.
| Values are:
| 0 – Center
| 1 – Top
| 2 – Bottom
| 3 – Multiline

Usage **In the painter** Select the control and set the value in the Properties view, General tab, Vertical Alignment option.

Examples

```
string setting
dwl\.Object\.b_name\.VTextAlign = "0"
setting = dwl\.Describe("b_name\.VTextAlign")
dwl\.Modify("b_name\.VTextAlign = '0'")
```

Width

Description The width of the specified control.
Applies to Button, Column, Computed Field, Graph, GroupBox, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls
Syntax PowerBuilder dot notation:

\[ dw\_control\.Object\.controlname\.Width \]

Describe and Modify argument:

\[ "controlname\.Width \{ = ' value ' \}" \]
### Usage

In the painter  Select the control and set the value in the Properties view, Position tab.

### Examples

```powershell
string setting
setting = dw1.Object.emp_name.Width

dw1.Object.emp_name.Width = 250

setting = dw1.Describe("emp_name.Width")
dw1.Modify("emp_name.Width=250")
```

---

**Width.Autosize**

#### Description

(RichText presentation style only) Whether the column or computed field input field adjusts its width according to the data it contains.

The Width.Autosize and Multiline properties can be set together so that the input field can display multiple lines.

#### Applies to

Column and Computed Field controls in the RichText presentation style

#### Syntax

PowerBuilder dot notation:

```
dw_control.Object.controlname.Width.Autosize
```

Describe and Modify argument:

"controlname.Width.Autosize { = 'value' }"

#### Parameter | Description
--- | ---
controlname | The name of the column or computed field for which you want to get or set the Autosize setting.
value | *(exp)* Whether the width of the input field adjusts according to the data it contains. Values are:
  - Yes – The width adjusts according to the data.
  - No – The width is fixed and is set to the value of the Width property.
Usage

**In the painter**  Select an input field so that it is flashing, then right-click and select Properties from the pop-up menu. Set the value on the property sheet, Input Field tab, Fixed Size option.

**Examples**

```powershell
string setting
setting = dw1.Object.emp_name.Width.Autosize

dw1.Object.emp_name.Width.Autosize = "yes"

setting = dw1.Describe("emp_name.Width.Autosize")

dw1.Modify("emp_name.Width.Autosize=yes")
```

**X**

**Description**  The distance of the specified control from the left edge of the DataWindow object.

**Applies to**  Button, Column, Computed Field, Graph, GroupBox, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**  PowerBuilder dot notation:

```
dw_control.Object.controlname.X
```

Describe and Modify argument:

"controlname.X { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control for which you want to get or set the x coordinate.</td>
</tr>
<tr>
<td>value</td>
<td><em>(exp)</em> An integer specifying the x coordinate of the control in the unit of measure specified for the DataWindow object. <em>Value</em> can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**  Select the control and set the value in the Properties view, Position tab.

**Examples**

```powershell
string setting
setting = dw1.Object.emp_name.X

dw1.Object.emp_name.X = 10

setting = dw1.Describe("emp_name.X")

dw1.Modify("emp_name.X=10")
```
**X1, X2**

**Description**
The distance of each end of the specified line from the left edge of the line’s band.

**Applies to**
Line controls

**Syntax**
PowerBuilder dot notation:

```
  dw_control.Object.controlname.X1
  dw_control.Object.controlname.X2
```

Describe and Modify argument:

```
"controlname.X1 { = 'value'}"
"controlname.X2 { = 'value'}"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the line for which you want to get or set one of the x coordinates.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) An integer specifying the x coordinate of the line in the unit of measure specified for the DataWindow object. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**
Select the control and set the value in the Properties view, Position tab.

**Examples**

```
string setting
setting = dw1.Object.line_1.X1
```

```
dw1.Object.line_1.X1 = 10
```

```
dw1.Object.line_1.X2 = 1000
```

```
setting = dw1.Describe("line_1.X1")
```

```
dw1.Modify("line_1.X1=10")
```

```
dw1.Modify("line_1.X2=1000")
```

---

**XHTMLGen.Browser**

**Description**
A string that identifies the browser in which XHTML generated within an XSLT style sheet is displayed.

**Applies to**
DataWindow objects

**Syntax**
PowerBuilder dot notation:

```
dw_control.Object.DataWindow.XHTMLGen.Browser
```

---

410  PowerBuilder
Describe and Modify argument:

“DataWindow.XHTMLGen.Browser { = ’value’ }”

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>(exp) A string identifying the browser in which you want to display the generated XHTML. The value should match the browser identifier part of the text string that the browser specifies in the HTTP header it sends to the server. This property is usually set dynamically on the server according to the HTTP header returned from the client. Recognized strings are listed in the Usage section below.</td>
</tr>
</tbody>
</table>

**Usage**

If the string specifies a browser that the DataWindow engine supports, the DataWindow generates an XSLT style sheet and JavaScript for XHTML transformation optimized for that browser. Browser-specific XSLT and JavaScript are generated only for Microsoft Internet Explorer 5.0 and later and Netscape 6.0 and later.

Browser identification strings are sent by the client to the server in the HTTP header. The server component can assign the HTTP_USER_AGENT value from the HTTP header to the Browser property.

The XML Web DataWindow generator recognizes these browsers:

<table>
<thead>
<tr>
<th>Browser</th>
<th>HTTP header string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Internet Explorer</td>
<td>Mozilla/4.0 (compatible; MSIE 5.0; Mozilla/4.0 (compatible; MSIE 5.5; Mozilla/4.0 (compatible; MSIE 6.x;</td>
</tr>
<tr>
<td>Netscape</td>
<td>Mozilla/5.0</td>
</tr>
</tbody>
</table>

**In the painter** On the Web Generation tab in the Properties view for the DataWindow object, select XHTML from the Format to Configure list and select a browser from the list.

**XMLGen.property**

**Description**

Settings that specify how XML is generated, whether client-side, postback, or callback paging is used, the physical path to which XML is published, and the URL referenced by the JavaScript that transforms the XML to XHTML.

**Applies to**

DataWindow objects

**Syntax**

PowerBuilder dot notation:

\[ dw\_control\_Object\_DataWindow\_XMLGen\_property \]
Describe and Modify argument:

"DataWindow.XMLGen.property { = value }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• Inline</td>
</tr>
<tr>
<td></td>
<td>• PublishPath</td>
</tr>
<tr>
<td></td>
<td>• ResourceBase</td>
</tr>
<tr>
<td>value</td>
<td>(exp) Inline – A boolean that specifies whether the XML generated for the XML Web DataWindow is generated inline to the XSLT transformation script. Values are:</td>
</tr>
<tr>
<td></td>
<td>true – The XML is generated within the XSLT transformation script.</td>
</tr>
<tr>
<td></td>
<td>false – (default) The XML is published to a separate document.</td>
</tr>
<tr>
<td></td>
<td>(exp) PublishPath – A string that specifies the physical path of the Web site folder to which PowerBuilder publishes the generated XML document that contains the XML Web DataWindow content.</td>
</tr>
<tr>
<td></td>
<td>(exp) ResourceBase – A string that specifies the URL of the generated XML document that contains the XML Web DataWindow content.</td>
</tr>
</tbody>
</table>

Usage

**Inline**  The XML published on the Internet in your XML Web DataWindow could contain sensitive data, and this data might be exposed to Internet users when published to a separate document. For increased security, if the Inline property is set to true, the XML is generated “inline” to the XSLT transformation script in the page that renders the control. If only authenticated users have access to this script, the security of the XML is ensured. Setting this property should have no adverse side effects on the caching efficiency of the control.

**PublishPath and ResourceBase**  The PublishPath folder must correspond to the URL specified in the ResourceBase property. At runtime, after PowerBuilder generates XML content to the PublishPath folder, client-side JavaScript in a generated page downloads it using a reference to the ResourceBase property. The JavaScript transforms the XML content to XHTML using the generated XSLT style sheet.

**In the painter**  On the Web Generation tab in the Properties view for the DataWindow object, select XML from the Format to Configure list and select the options you require.
Examples

These statements set the XMLGen.ResourceBase and XMLGen.PublishPath properties:

```
      'http://www.myserver.com/xmlsource'
dw1.Object.DataWindow.XMLGen.PublishPath= &
      'C:\work\outputfiles\xmlsource'
dw1.Modify("DataWindow.XMLGen.PublishPath=
      'C:\Inetpub\wwwroot\MyWebApp\generatedfiles'")
dw1.Modify("DataWindow.XMLGen.ResourceBase=
      '/MyWebApp/generatedfiles'")
```

This statement sets the XMLGen.Inline property so that XML is generated inline:

```
dw1.Modify("DataWindow.XMLGen.Inline='1'")
```

**XSLTGen.property**

**Description**

Settings that specify the physical path to which the generated XSLT style sheet is published and the URL referenced by the JavaScript that transforms the XML to XHTML.

**Applies to**

DataWindow objects

**Syntax**

PowerBuilder dot notation:

```
dw_control.Object.DataWindow.XSLTGen.property
```

**Describe and Modify argument:**

```
"DataWindow.XSLTGen.property { = 'value' }"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>- PublishPath</td>
</tr>
<tr>
<td></td>
<td>- ResourceBase</td>
</tr>
<tr>
<td>value</td>
<td>(exp) PublishPath – A string that specifies the physical path of the Web site folder to which PowerBuilder publishes the generated XSLT style sheet</td>
</tr>
<tr>
<td></td>
<td>(exp) ResourceBase – A string that specifies the URL of the generated XSLT style sheet</td>
</tr>
</tbody>
</table>
**Y**

**Usage**

The PublishPath folder must correspond to the URL specified in the ResourceBase property. At runtime, after PowerBuilder generates the XSLT style sheet to the PublishPath folder, client-side JavaScript in a generated page downloads it using a reference to the ResourceBase property. The JavaScript transforms the XML content to XHTML using the generated XSLT style sheet.

**In the painter**

On the Web Generation tab in the Properties view for the DataWindow object, select XSLT from the Format to Configure list and specify the ResourceBase and Publish Path locations.

**Examples**

These statements set the XSLTGen.ResourceBase and XSLTGen.PublishPath properties:

```powerbuilder
  'http://www.myserver.com/xmlsource'
  dw1.Object.DataWindow.XSLTGen.PublishPath= &
  'C:\work\outputfiles\xmlsource'
```

---

**Y**

**Description**

The distance of the specified control from the top of the control’s band.

**Applies to**

Button, Column, Computed Field, Graph, GroupBox, OLE, Oval, Picture, Rectangle, Report, RoundRectangle, TableBlob, and Text controls

**Syntax**

PowerBuilder dot notation:

```
  dw_control.Object.controlname.Y
```

**Describe and Modify argument:**

"controlname.Y { = 'value' }"

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the control for which you want to get or set the y coordinate.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) An integer specifying the y coordinate of the control in the unit of measure specified for the DataWindow object. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**

**In the painter**

Select the control and set the value in the Properties view, Position tab.

**Examples**

```powerbuilder
  string setting
  setting = dw1.Object.emp_name.Y
  dw1.Object.emp_name.Y = 100
  setting = dw1.Describe("emp_name.Y")
  dw1.Modify("emp_name.Y=100")
```
**Y1, Y2**

**Description**
The distance of each end of the specified line from the top of the line’s band.

**Applies to**
Line controls

**Syntax**
PowerBuilder dot notation:

```
    dw_control.Object.controlname.Y1
    dw_control.Object.controlname.Y2
```

Describe and Modify argument:

```
"controlname.Y1 { = 'value'}"
"controlname.Y2 { = 'value'}"
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlname</td>
<td>The name of the line for which you want to get or set one of the y coordinates.</td>
</tr>
<tr>
<td>value</td>
<td>(exp) An integer specifying the y coordinate of the line in the unit of measure specified for the DataWindow object. Value can be a quoted DataWindow expression.</td>
</tr>
</tbody>
</table>

**Usage**
**In the painter** Select the control and set the value in the Properties view, Position tab.

**Examples**

```
    string setting
    setting = dw1.Object.line_1.Y1
    dw1.Object.line_1.Y1 = 50
    dw1.Object.line_1.Y2 = 50

    setting = dw1.Describe("line_1.Y1")
    dw1.Modify("line_1.Y1=50")
    dw1.Modify("line_1.Y2=50")
```

**Zoom**

**Description**
The scaling percentage of the DataWindow object.

**Applies to**
DataWindows

**Syntax**
PowerBuilder dot notation:

```
    dw_control.Object.DataWindow.Zoom
```

Describe and Modify argument:

```
"DataWindow.Zoom { = value }"
```
Zoom

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>An integer specifying the scaling percentage of the DataWindow object. The default is 100%.</td>
</tr>
</tbody>
</table>

Usage

**In the painter**  To see the effect of different zoom factors in Preview mode, use Design>Zoom. The zoom factor you set in the painter is not used at runtime.

Limitation
The zoom property is not supported for the Graph, RichText, and OLE DataWindow styles.

Examples

```powerbuilder
string setting
setting = dw1.Object.DataWindow.Zoom

dw1.Object.DataWindow.Zoom = 50

setting = dw1.Describe("DataWindow.Zoom")
dw1.Modify("DataWindow.Zoom=50")
```
CHAPTER 4

Accessing Data in Code

About this chapter

This chapter explains the syntax for constructing expressions that access data in a DataWindow object.

Contents

<table>
<thead>
<tr>
<th>Topic</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessing data and properties in DataWindow</td>

<tr>
<td>Syntaxes for DataWindow data expressions</td>
<td>426</td>
</tr>
</tbody>
</table>

Accessing data and properties in DataWindow programming environments

In each programming environment, you can use methods and sometimes expressions to access the data and properties of a DataWindow object.

Data

Methods for single items of data These include GetItemString for data and Describe and Modify for properties. These methods are available in all environments.

DataWindow data expressions These let you access single items and blocks of data. You can access data in a single column, data in selected rows, and ranges of rows and columns.

Data expressions have a variety of syntaxes depending on the amount of data you want to access. Data expressions are not supported by the DataWindow Web Control for ActiveX.

You can get and set data values using the following syntax:

```
dwcontrol.Object.Data [ startrownum, startcolnum, endrownum, endcolnum ]
```

For a list of syntaxes, see “Syntaxes for DataWindow data expressions” on page 426.
Techniques for accessing data

Properties

Methods for properties  These are Describe and Modify. These methods are available in all environments.

DataWindow property expressions  These let you get and set the values of properties of the DataWindow definition and of controls contained within the definition, such as columns and text labels. Property expressions are not supported by the DataWindow Web Control for ActiveX.

Property expressions take this form:

\[ \text{dwcontrol.Object.columnname.columnproperty} = \text{value} \]

Where to find information

This chapter discusses techniques for accessing data with emphasis on data expressions.

For information on accessing properties using methods or property expressions, see Chapter 5, "Accessing DataWindow Object Properties in Code."

Techniques for accessing data

Two techniques

There are two ways to access data values in a DataWindow control:

- **Methods**  SetItem and the group of GetItem methods access single values in specific rows and columns. For example:

  \[
  \begin{align*}
  \text{dw_1.SetItem(1, "empname", "Phillips")} \\
  \text{ls_name = dw_1.GetItemString(1, "empname")}
  \end{align*}
  \]

- **Expressions**  DataWindow data expressions use dot notation and can refer to single items, columns, blocks of data, selected data, or the whole DataWindow control. For example:

  \[
  \begin{align*}
  \text{dw_1.Object.empname[1]} &= \text{"Phillips"} \\
  \text{dw_1.Object.Data[1,1]} &= \text{"Phillips"}
  \end{align*}
  \]

Both methods allow you to access data in any buffer and to get original or current values.
The technique you use depends on how much data you are accessing and whether you know the names of the DataWindow columns when the script is compiled:

**Table 4-1: Which technique to use when accessing data**

<table>
<thead>
<tr>
<th>If you want to access</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>A single item</td>
<td>Either an expression or a method. Both are equally efficient when referring to single items.</td>
</tr>
<tr>
<td></td>
<td><strong>Exception</strong>&lt;br&gt;If you want to use a column’s name rather than its number, and the name is not known until runtime, use a method; methods allow you to name the column dynamically.</td>
</tr>
</tbody>
</table>

More than one item, such as:
- All the data in a column
- A block of data specified by ranges of rows and columns
- Data in selected rows
- All the data in the DataWindow

<table>
<thead>
<tr>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>An expression. Specifying the data you want in a single statement is much more efficient than calling the methods repeatedly in a program loop.</td>
</tr>
</tbody>
</table>

**What’s in this section**
The rest of this section describes how to construct expressions for accessing DataWindow data. The section “Syntaxes for DataWindow data expressions” on page 426 provides reference information on the syntaxes for data expressions.

**For information on methods**
For information about using methods for accessing data, see SetItem, GetItemDate, GetItemDateTime, GetItemDecimal, GetItemNumber, GetItemString, and GetItemTime in Chapter 9, “Methods for the DataWindow Control.”

**About DataWindow data expressions**
The Object property of the DataWindow control lets you specify expressions that refer directly to the data of the DataWindow object in the control. This direct data manipulation allows you to access small and large amounts of data in a single statement, without calling methods.

There are several variations of data expression syntax, divided into three groups. This section summarizes these syntaxes. The syntaxes are described in detail later in this chapter.
Techniques for accessing data

Data in columns or computed fields when you know the name

**One or all items** (if `rownum` is absent, include either `buffer` or `datasource`)

```
dwcontrol.Object.columnname {buffer} {datasource} { [ rownum ] }
```

Returns a single value (for a specific row number) or an array of values (when `rownum` is omitted) from the column.

See “Syntax for one or all data items in a named column” on page 427.

**Selected items**

```
dwcontrol.Object.columnname {Primary} {datasource} .Selected
```

Returns an array of values from the column with an array element for each selected row.

See “Syntax for selected data in a named column” on page 430.

**Range of items**

```
dwcontrol.Object.columnname {buffer} {datasource} [ startrownum, endrownum ]
```

Returns an array of values from the column with an array element for each row in the range.

See “Syntax for a range of data in a named column” on page 431.

Data in numbered columns

**Single items**

```
dwcontrol.Object.Data {buffer} {datasource} [ rownum, colnum ]
```

Returns a single item whose datatype is the datatype of the column.

See “Syntax for a single data item in a DataWindow” on page 433.

**Blocks of data** involving a range of rows and columns

```
dwcontrol.Object.Data {buffer} {datasource} [ startrownum, startcolnum, endrownum, endcolnum ]
```

Returns an array of structures or user objects. The structure elements match the columns in the range. There is one array element for each row in the range.

See “Syntax for data in a block of rows and columns” on page 434.

Whole rows

**Single row or all rows**

```
dwcontrol.Object.Data {buffer} {datasource} { [ rownum ] }
```

Returns one structure or user object (for a single row) or an array of them (for all rows). The structure elements match the columns in the DataWindow object.

See “Syntax for data in a single row or all rows” on page 436.
CHAPTER 4  Accessing Data in Code

Selected rows

\[ dwcontrol.Object.Data \{ .Primary \} \{ .datasource \} .Selected \]

Returns an array of structures or user objects. The structure elements match the columns in the DataWindow object. There is one array element for each selected row.

See “Syntax for all data from selected rows” on page 438.

Summary of syntaxes

This diagram summarizes the variations in data expression syntax:

*Figure 4-1: Variations in data expression syntax*

For information about getting and setting values of DataWindow object properties using a similar syntax, see Chapter 5, “Accessing DataWindow Object Properties in Code.”

When a DataWindow data expression is evaluated

Expressions that refer to DataWindow data are not verified until execution of your application.

No compiler checking

When your script is compiled, PowerBuilder does not verify the parameters of the expression that follow the Object property. Your application can select or change the DataWindow object in a DataWindow control at runtime without invalidating the compiled script.

Potential execution errors

If the datatype of the expression is not compatible with how the expression is used, or if the specified rows or columns do not exist, an error will occur at runtime.

You can handle the error by surrounding the expression in a try-catch block and catching any DWRuntimeErrors, or by writing a script for the DataWindow control’s Error event.
Getting and storing the data from a DataWindow data expression

A DataWindow data expression can return a large amount of data.

**Data structures for data**

- **Single row and column** When your data expression refers to a single row and column, you can assign the data to a variable whose data matches the column’s datatype. When the expression refers to a single column but can refer to multiple rows, you must specify an array of the appropriate datatype.

- **More than one column** When the expression refers to more than one column, you can get or set the data with a structure or user object. When you create the definition, you must assign datatypes to the fields (in a structure) or instance variables (in a user object) that match the datatypes of the columns. When your expression refers to multiple rows, you get an array of the structure or user object.

Likewise, if you want to set data in the DataWindow control, you will set up the data in structures or user objects whose elements match the columns referred to in the expression. An array of those structures or user objects will provide data for multiple rows.

**Datatypes** For matching purposes, the datatypes should be appropriate to the data—for example, any numeric datatype matches any other numeric type.

The following table presents some examples of data specified by an expression and the type of data structures you might define for storing the data:

<table>
<thead>
<tr>
<th>Type of selection</th>
<th>Sample data storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>A single item</td>
<td>A single variable of the appropriate datatype.</td>
</tr>
<tr>
<td>A column of values</td>
<td>An array of the appropriate datatype.</td>
</tr>
<tr>
<td>A row</td>
<td>A structure whose elements have datatypes that match the DataWindow object’s columns.</td>
</tr>
<tr>
<td></td>
<td>A user object whose instance variables match the DataWindow object’s columns.</td>
</tr>
<tr>
<td>Selected rows or all rows</td>
<td>An array of the structure or user object defined for a row.</td>
</tr>
<tr>
<td>A block of values</td>
<td>An array of structures or user objects whose elements or instance variables match the columns included in the selected range.</td>
</tr>
</tbody>
</table>
Assigning data to arrays

When a data expression is assigned to an array, values are assigned beginning with array element 1 regardless of the starting row number. If the array is larger than the number of rows accessed, elements beyond that number are unchanged. If it is smaller, a variable-size array will grow to hold the new values. However, a fixed-size array that is too small for the number of rows will cause an execution error.

Two ways to instantiate user objects

A user object needs to be instantiated before it is used.

One way is to use the CREATE statement after you declare the user object. If you declare an array of the user object, you must use CREATE for each array element.

The second way is to select the Autoinstantiate box for the user object in the User Object painter. When you declare the user object in a script, the user object will be automatically instantiated, like a structure.

Any datatype and data expressions

The actual datatype of a DataWindow data expression is Any, which allows the compiler to process the expression even though the final datatype is unknown. When data is accessed at runtime, you can assign the result to another Any variable or to a variable, structure, or user object whose datatype matches the real data.

Examples

A single value

This example gets a value from column 2, whose datatype is string:

```plaintext
string ls_name
ls_name = dw_1.Object.Data[1,2]
```

A structure that matches DataWindow columns

In this example, a DataWindow object has four columns:

- An ID (number)
- A name (string)
- A retired status (boolean)
- A birth date (date)

A structure to hold these values has been defined in the Structure painter. It is named `str_empdata` and has four elements whose datatypes are integer, string, boolean, and date. To store the values of an expression that accesses some or all the rows, you need an array of `str_empdata` structures to hold the data:

```plaintext
str_empdata lstr_currdata[]
lstr_currdata = dw_1.Object.Data
```
Techniques for accessing data

After this example executes, the upper bound of the array of structures, which is variable-size, is equal to the number of rows in the DataWindow control.

A user object that matches DataWindow columns If the preceding example involved a user object instead of a structure, then a user object defined in the User Object painter, called `uo_empdata`, would have four instance variables, defined in the same order as the DataWindow columns:

- integer id
- string name
- boolean retired
- date birthdate

Before accessing three rows, three array elements of the user object have been created (you could use a `FOR NEXT` loop for this). The user object was not defined with Autoinstantiate enabled:

```
uo_empdata luo_empdata[3]
luo_empdata[1] = CREATE uo_empdata
luo_empdata[2] = CREATE uo_empdata
luo_empdata[3] = CREATE uo_empdata
luo_empdata = dw_1.Object.Data[1,1,3,4]
```

Setting DataWindow data with a DataWindow data expression

When you set data in a DataWindow control, the datatypes of the source values must match the datatypes of the columns being set.

When your data expression refers to a single row and column, you can set the value in the DataWindow control with a value that matches the column’s datatype. When you are setting values in a single column and specifying an expression that can refer to multiple rows, the values you assign must be in an array of the appropriate datatype.

When the expression refers to more than one column, you can assign the data with a structure or user object to the DataWindow data. When you create the definition, the fields (in a structure) or instance variables (in a user object) must match the columns. There must be the same number of fields or variables, defined in the same order as the columns, with compatible datatypes.

When your expression can refer to multiple rows, you need an array of the structure or user object.
**Using arrays to set values**

You do not have to know in advance how many rows are involved when you are setting data in the DataWindow control. PowerBuilder uses the number of elements in the source array and the number of rows in the target expression to determine how to make the assignment and whether it is necessary to insert rows.

If the target expression is *selected rows or a range of rows*, then:

- When there are *more* array elements than target rows, the extra array elements are ignored
- When there are *fewer* array elements than target rows, the column(s) in the extra target rows are filled with default values

If the target expression is *all rows but not all columns*, then:

- When there are *more* array elements than target rows, the extra array elements are ignored
- When there are *fewer* array elements than target rows, only the first rows up to the number of array elements are affected

If the target expression is *all rows and all columns*, then the source data replaces all the existing rows, resetting the DataWindow control to the new data.

**Inserting new rows**

When you are setting data and you specify a range, then if rows do not exist in that range, rows are inserted to fill the range. For example, if the DataWindow control has four rows and your expression says to assign data to rows 8 through 12, then eight more rows are added to the DataWindow control. The new rows use the initial default values set up for each column. After the rows are inserted, the array of source data is applied to the rows as described above.

**Examples**

These examples refer to a DataWindow object that has three columns: emp_id, emp_lname, and salary. The window declares these arrays as instance variables and the window’s Open event assigns four elements to each array:

```java
integer ii_id[]
string is_name[]
double id_salary[]
uo_empdata iuo_data[]
uo_empid_name iuo_id[]
```

The uo_empdata user object has three instance variables: id, name, and salary. The uo_empid_name user object has two instance variables: id and name.
This example sets `emp_lname` in the selected rows to the values of `is_name`, an array with four elements. If two rows are selected, only the first two values of the array are used. If six rows are selected, the last two rows of the selection are set to an empty string:

```powershell
dw_1.Object.emp_lname.Selected = is_name
```

This example sets `salary` in rows 8 to 12 to the values in the array `id_salary`. The `id_salary` array has only four elements, so the extra row in the range is set to 0 or a default value:

```powershell
dw_1.Object.salary[8,12] = id_salary
```

This statement resets the DataWindow control and inserts four rows to match the array elements of `iuo_data`:

```powershell
dw_1.Object.Data.Primary = iuo_data
```

This example sets columns 1 and 2 in rows 5 to 8 to the values in the array `iuo_id`:

```powershell
dw_1.Object.Data.Primary[5,1, 8,2] = iuo_id
```

This example sets `emp_id` in the first four rows to the values in the `ii_id` array. Rows 5 through 12 are not affected:

```powershell
dw_1.Object.emp_id.Primary = ii_id
```

**Syntaxes for DataWindow data expressions**

This section describes in detail the syntaxes that were summarized in “About DataWindow data expressions” on page 419.

You can think of the syntaxes as grouped in three categories:

- **Expressions with a named column or computed field**
  - “Syntax for one or all data items in a named column” on page 427
  - “Syntax for selected data in a named column” on page 430
  - “Syntax for a range of data in a named column” on page 431

- **Expressions with column numbers**
  - “Syntax for a single data item in a DataWindow” on page 433
  - “Syntax for data in a block of rows and columns” on page 434
Expressions that access whole rows

- “Syntax for data in a single row or all rows” on page 436
- “Syntax for all data from selected rows” on page 438

Syntax for one or all data items in a named column

Description
A DataWindow data expression can access a single item in a column or computed field when you specify the control name and a row number. It accesses all the data in the column when you omit the row number.

Syntax

```
dwcontrol.Object.columnname { .buffer } { .datasource } { [ rownum ] }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set data.</td>
</tr>
<tr>
<td><code>columnname</code></td>
<td>The name of a column or computed field in the DataWindow object in <code>dwcontrol</code>. If the column or computed field does not exist at runtime, an execution error occurs.</td>
</tr>
<tr>
<td><code>buffer</code></td>
<td>(optional) The name of the buffer from which you want to get or set data. Values are:</td>
</tr>
<tr>
<td></td>
<td>- Primary – (Default) The data in the primary buffer (the data that has not been deleted or filtered out).</td>
</tr>
<tr>
<td></td>
<td>- Delete – The data in the delete buffer (data deleted from the DataWindow control).</td>
</tr>
<tr>
<td></td>
<td>- Filter – The data in the filter buffer (data that was filtered out).</td>
</tr>
<tr>
<td><code>datasource</code></td>
<td>(optional) The source of the data. Values are:</td>
</tr>
<tr>
<td></td>
<td>- Current – (Default) The current values in the DataWindow control.</td>
</tr>
<tr>
<td></td>
<td>- Original – The values that were initially retrieved from the database. For a computed field, you must specify Original because computed fields cannot be changed and do not have current values.</td>
</tr>
<tr>
<td><code>rownum</code></td>
<td>(optional) The row number of the desired item. The row number must be enclosed in brackets.</td>
</tr>
</tbody>
</table>

To access all the data in the column, omit `rownum`.

When buffer or datasource is not optional
When `rownum` is omitted, you must specify at least one of the other elements in the expression: either `buffer` or `datasource`. 
**Syntaxes for DataWindow data expressions**

**Return value**

The expression has a datatype of Any. The expression returns a single value (for a specific row number) or an array of values (when `rownum` is omitted). Each value has a datatype of `columnname`.

**Usage**

**Is the expression a DWOBJECT or data?**

When you want to access all the data in the column, remember to specify at least one of the other optional parameters. Otherwise, the expression you specify refers to the column `control`, not its data. This expression refers to the DWOBJECT `empname`, not the data in the column:

```
dw_1.Object.empname
```

In contrast, these expressions all refer to data in the `empname` column:

```
dw_1.Object.empname.Primary // All rows
```

**Row numbers for computed fields**

When you refer to a control in a band other than the detail band (usually a computed field) you still specify a row number. For the header, footer, or summary, specify a row number of 1. For the group header or trailer, specify the group number:

```
dw_1.Object.avg_cf[1]
```

If you specify nothing after the computed field name, you refer to the computed field DWOBJECT, not the data. For a computed field that occurs more than once, you can get all values by specifying `buffer` or `datasource` instead of `rownum`, just as for columns.

**When the expression is an array**

When the expression returns an array (because there is no row number), you must assign the result to an array, even if you know there is only one row in the result.

This expression returns an array, even if there is only one row in the DataWindow control:

```
dw_1.Object.empname.Primary
```

This expression returns a single value:

```
dw_1.Object.empname[22]
```

**Examples**

Because the default setting is current values in the primary buffer, the following expressions are equivalent—both get the value in row 1 for the `emp_name` column:

```
dw_1.Object.emp_name[1]
```
This statement sets the emp_name value in row 1 to Wilson:

dw_1.Object.emp_name[1] = "Wilson"

This statement gets values for all the emp_name values that have been retrieved and assigns them to an array of strings:

```csharp
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Current
```

This statement gets current values of emp_name from all rows in the filter buffer:

```csharp
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Filter
```

This statement gets original values of emp_name from all rows in the filter buffer:

```csharp
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Filter.Original
```

This statement gets the current value of emp_name from row 14 in the delete buffer:

```csharp
string ls_name
ls_name = dw_1.Object.emp_name.Delete[14]
```

This statement gets the original value of emp_name from row 14 in the delete buffer:

```csharp
string ls_name
ls_name = dw_1.Object.emp_name.Delete.Original[14]
```

This statement gets all the values of the computed field review_date:

```csharp
string ld_review[]
ld_review = dw_1.Object.review_date.Original
```
Syntax for selected data in a named column

Description
A DataWindow data expression uses the Selected property to access values in a named column or computed field for the currently selected rows. Selected data is always in the primary buffer.

Syntax
```
dwcontrol.Object.columnname{"Primary} {“datasource “}.Selected
```

Parameter | Description
---|---
dwcontrol | The name of the DataWindow control or child DataWindow in which you want to get or set data.
columnname | The name of a column or computed field in the DataWindow object in `dwcontrol`. If the column or computed field does not exist at runtime, an execution error occurs.
datasource (optional) | The source of the data. Values are:
- Current – (Default) The current values in the DataWindow control.
- Original – The values that were initially retrieved from the database. For a computed field, you must specify Original (because computed fields cannot be changed and do not have current values).

Return value
The datatype of the expression is Any. The expression returns an array of values with the datatype of `columnname`.

Usage
When you specify selected values, the expression always returns an array and you must assign the result to an array, even if you know there is only one row selected.

For selected rows, the primary buffer is the only applicable buffer. For consistency, you can include Primary in this syntax but it is not necessary.

Examples
Because the primary buffer is the only applicable buffer for selected data and current data is the default, these expressions are all equivalent. They access values in the emp_name column for selected rows:

```
dw_1.Object.emp_name.Selected
dw_1.Object.emp_name.Primary.Selected
dw_1.Object.emp_name.Current.Selected
dw_1.Object.emp_name.Primary.Current.Selected
```

These expressions both access original values for selected rows:

```
dw_1.Object.emp_name.Original.Selected
dw_1.Object.emp_name.Primary.Original.Selected
```
This example sets the emp_name value in the first selected row to an empty string. The rest of the selected rows are set to a default value, which can be an empty string:

```c
string ls_empty[]
ls_empty[1] = ""
dw_1.Object.emp_lname.Selected = ls_empty
```

This statement gets the original emp_name values in selected rows and assigns them to an array of strings:

```c
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Original.Selected
```

### Syntax for a range of data in a named column

**Description**

A DataWindow data expression accesses values in a named column or computed field for a range of rows when you specify the starting and ending row numbers.

**Syntax**

```
dwcontrol.Object.columnname { .buffer } { .datasource } [ startrownum, endrownum ]
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set data.</td>
</tr>
<tr>
<td><code>columnname</code></td>
<td>The name of a column or computed field in the DataWindow object in <code>dwcontrol</code>. If the column or computed field does not exist at runtime, an execution error occurs.</td>
</tr>
</tbody>
</table>
| `buffer` (optional) | The name of the buffer from which you want to get or set data. Values are:  
- Primary – (Default) The data in the primary buffer (the data that has not been deleted or filtered out).  
- Delete – The data in the delete buffer (data deleted from the DataWindow control).  
- Filter – The data in the filter buffer (data that was filtered out).  |
| `datasource` (optional) | The source of the data. Values are:  
- Current – (Default) The current values in the DataWindow control.  
- Original – The values that were initially retrieved from the database. For a computed field, you must specify Original (because computed fields cannot be changed and do not have current values).  |
| `startrownum` | The number of the first row in the desired range of rows. |
Syntaxes for DataWindow data expressions

Return value
The datatype of the expression is Any. The expression returns an array of values with an array element for each row in the range. Each value’s datatype is the datatype of columnname.

Usage
When you specify a range, the expression always returns an array and you must assign the result to an array, even if you know there is only one value in the result. For example, this expression returns an array of one value:

dw_1.Object.empname[22,22]

Examples
Because the primary buffer and current data are the default, these expressions are all equivalent:

dw_1.Object.emp_name[11,20]
dw_1.Object.emp_name.Primary[11,20]

This example resets the emp_name value in rows 11 through 20 to an empty string. Rows 12 to 20 are set to a default value, which may be an empty string:

```powerbuilder
string ls_empty[]
ls_empty[1] = ""
dw_1.Object.emp_name[11,20] = &
{"","","","","","","","","
```

This statement gets the original emp_name values in rows 11 to 20 and assigns them to elements 1 to 10 in an array of strings:

```powerbuilder
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Original[11,20]
```

This statement gets current values of emp_name from rows 5 to 8 in the Filter buffer and assigns them to elements 1 to 4 in an array of strings:

```powerbuilder
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Filter[5,8]
```

This statement gets original values of emp_name instead of current values, as shown in the previous example:

```powerbuilder
string ls_namearray[]
ls_namearray = &
dw_1.Object.emp_name.Filter.Original[5,8]
```
This statement gets current values of emp_name from rows 50 to 200 in the delete buffer and assigns them to elements 1 to 151 in an array of strings:

```csharp
string ls_namearray[]
ls_namearray = dw_1.Object.emp_name.Delete[50,200]
```

This statement gets original values of emp_name instead of current values, as shown in the previous example:

```csharp
string ls_namearray[]
ls_namearray = &
    dw_1.Object.emp_name.Delete.Original[50,200]
```

### Syntax for a single data item in a DataWindow

**Description**

A DataWindow data expression accesses a single data item when you specify its row and column number.

**Syntax**

```
dwcontrol.Object.Data { .buffer } { .datasource } [ rownum, colnum ]
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set data.</td>
</tr>
<tr>
<td><code>buffer</code></td>
<td>The name of the buffer from which you want to get or set data. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Primary – (Default) The data in the primary buffer (the data that has not been deleted or filtered out).</td>
</tr>
<tr>
<td></td>
<td>• Delete – The data in the delete buffer (data deleted from the DataWindow control).</td>
</tr>
<tr>
<td></td>
<td>• Filter – The data in the filter buffer (data that was filtered out).</td>
</tr>
<tr>
<td><code>datasource</code></td>
<td>The source of the data. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Current – (Default) The current values in the DataWindow control.</td>
</tr>
<tr>
<td></td>
<td>• Original – The values that were initially retrieved from the database.</td>
</tr>
<tr>
<td><code>rownum</code></td>
<td>The row number of the desired item.</td>
</tr>
<tr>
<td><code>colnum</code></td>
<td>The column number of the desired item.</td>
</tr>
</tbody>
</table>

The row and column numbers must be enclosed in brackets and separated by commas.

**Return value**

The datatype of the expression is Any. The expression returns a single item in the DataWindow control. Its datatype is the datatype of the column.
Syntaxes for DataWindow data expressions

Examples

These expressions both refer to a single item in row 1, column 2. The expressions access current data in the primary buffer:

```
dw_1.Object.Data[1,2]
dw_1.Object.Data.Primary.Current[1,2]
```

This statement changes the value of the original data to 0 for the item in row 1, column 2 in the Filter buffer. Column 2 holds numeric data:

```
dw_1.Object.Data.Filter.Original[1,2] = 0
```

Syntax for data in a block of rows and columns

Description

A DataWindow data expression accesses data in a range of rows and columns when you specify the starting and ending row and column numbers.

Syntax

```
dwcontrol.Object.Data {buffer} {datasource} [startrownum, startcolnum, endrownum, endcolnum]
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set data.</td>
</tr>
<tr>
<td><code>buffer</code></td>
<td>(optional) The name of the buffer from which you want to get or set data. Values are:</td>
</tr>
<tr>
<td></td>
<td>- Primary – (Default) The data in the primary buffer (the data that has not been deleted or filtered out).</td>
</tr>
<tr>
<td></td>
<td>- Delete – The data in the delete buffer (data deleted from the DataWindow control).</td>
</tr>
<tr>
<td></td>
<td>- Filter – The data in the filter buffer (data that was filtered out).</td>
</tr>
<tr>
<td><code>datasource</code></td>
<td>(optional) The source of the data. Values are:</td>
</tr>
<tr>
<td></td>
<td>- Current – (Default) The current values in the DataWindow control.</td>
</tr>
<tr>
<td></td>
<td>- Original – The values that were initially retrieved from the database.</td>
</tr>
<tr>
<td><code>startrownum</code></td>
<td>The number of the first row in the desired range of rows.</td>
</tr>
<tr>
<td><code>startcolnum</code></td>
<td>The number for the first column in the range.</td>
</tr>
<tr>
<td><code>endrownum</code></td>
<td>The number of the last row in the range.</td>
</tr>
<tr>
<td><code>endcolnum</code></td>
<td>The number for the last column in the range.</td>
</tr>
</tbody>
</table>

The row and column numbers must be enclosed in brackets and separated by commas.
Return value  The datatype of the expression is Any. The expression returns an array of structures or user objects. There is one structure element or user object instance variable for each column in the designated range. The datatype of each element matches the datatype of the corresponding column. There is one structure or user object in the array for each row in the range of rows.

Usage  When you specify a block, the expression always returns an array and you must assign the result to an array, even if you know there is only one structure in the result.

This expression returns an array of one structure from row 22:

\[
\text{dw}_1.\text{Object}.\text{data}[22,1,22,4]
\]

This expression returns an array of one value from row 22, column 1:

\[
\text{dw}_1.\text{Object}.\text{data}[22,1,22,1]
\]

Examples  These statements both refer to data in the first ten rows and first four columns of the DataWindow object in the control \text{dw}_1. The primary buffer and current data are the default:

\[
\text{dw}_1.\text{Object}.\text{Data}[1,1,10,4] \quad \text{dw}_1.\text{Object}.\text{Data}.\text{Primary}.\text{Current}[1,1,10,4]
\]

This example gets employee IDs and last names for all the rows in the delete buffer. The IDs and names are the first two columns. It saves the information in a structure, called \text{str_namelist}, of two elements: an integer called \text{id} and a string called \text{lastname}. The structure was defined previously in the Structure painter. The list of IDs and names is then saved in the file \text{DELETED.TXT}:

\[
\begin{align*}
\text{integer } & \text{li_fileNum} \\
\text{long } & \text{ll_deletedrows} \\
\text{str_namelist } & \text{lstr_namelist}[] \\
\text{ll_deletedrows} & = \text{dw}_1.\text{DeletedCount}() \\
\text{lstr_namelist} & = & \\
& \text{dw}_1.\text{Object}.\text{Data}.\text{Delete}[1,1, \text{ll_deletedrows},2] \\
\text{li_fileNum} & = \text{FileOpen("C:\HR\DELETED.TXT", \\
& \text{LineMode!, Write!)} \\
\text{FOR } & \text{ll_count} = 1 \text{ to UpperBound(lstr_namelist)} \\
& \text{FileWrite(li_fileNum, \\
& \text{String(lstr_namelist.id) } + & \\
& " " + & \\
& \text{lstr_namelist.lastname } + & \\
& "-r-n") \\
\text{NEXT} \\
& \text{FileClose(li_fileNum)}
\end{align*}
\]
Using the structure from the previous example that holds IDs and last names, this example sets all the IDs and last names in the DataWindow control to null:

```powerbuilder
long ll_n
str_namelist lstr_namelist[]
SetNull(lstr_namelist[1].id)
SetNull(lstr_namelist[1].lastname)
FOR ll_n = 2 to dw_1.RowCount()
    lstr_namelist[ll_n] = lstr_namelist[1]
NEXT
dw_1.Object.Data[1,1, dw_1.RowCount(),2] = lstr_data
```

### Syntax for data in a single row or all rows

**Description**
A DataWindow data expression accesses a single row when you specify the row number. It accesses all the data in the DataWindow control when you omit the row number.

**Syntax**

```
dwcontrol.Object.Data {buffer} {datasource} { [rownum] }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>dwcontrol</strong></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set data.</td>
</tr>
<tr>
<td><strong>buffer</strong></td>
<td>(optional) The name of the buffer from which you want to get or set data. Values are:</td>
</tr>
<tr>
<td><strong>datasource</strong></td>
<td>(optional) The source of the data. Values are:</td>
</tr>
<tr>
<td><strong>rownum</strong></td>
<td>(optional) The number of the row you want to access. To access data for all rows, omit rownum. The row number must be enclosed in brackets.</td>
</tr>
</tbody>
</table>
Return value

The datatype of the expression is Any. The expression returns one structure or user object (for a single row) or an array of them (for all rows). There is one structure element or instance variable for each column in the DataWindow object. The datatype of each element matches the datatype of the corresponding column.

Usage

When you omit the row number, the expression always returns an array, and you must assign the result to an array, even if you know there is only one row in the DataWindow control.

Examples

These statements both access current data for row 5 in the primary buffer in the DataWindow object contained in the DataWindow control dw_1:

```
```

This example assigns all the data in dw_1 to the Any variable la Dwdata. The value assigned to la Dwdata is an array of data structures whose members match the column datatypes:

```
any la Dwdata
la Dwdata = dw_1.Object.Data
```

This example assigns all the data in the delete buffer for dw_1 to the Any variable la Dwdata:

```
any la Dwdata
la Dwdata = dw_1.Object.Data.Delete
```

This example replaces all the data in the nested report in row 2 with data from dw_2. The columns in the DataWindow object in dw_2 must match the columns in the DataWindow object for the nested report:

```
dw_2.Object.Data
```
Syntaxes for DataWindow data expressions

Syntax for all data from selected rows
Description
A DataWindow data expression accesses all the data in the currently selected rows when you specify the Data and Selected properties. Selected rows are always in the primary buffer.

Syntax
```
dwcontrol.Object.Data {,Primary } {,datasource }.Selected
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set data.</td>
</tr>
<tr>
<td>datasource</td>
<td>(optional) The source of the data. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Current – (Default) The current values in the DataWindow control.</td>
</tr>
<tr>
<td></td>
<td>• Original – The values that were initially retrieved from the database.</td>
</tr>
</tbody>
</table>

Return values
The datatype of the expression is Any. The expression returns an array of structures or user objects. There is one structure element or instance variable for each column in the DataWindow object. The datatype of each element matches the datatype of the corresponding column.

Usage
When you specify selected rows, the expression always returns an array, and you must assign the result to an array even if you know there is only one row selected.

Examples
Because the primary buffer is the only applicable buffer for selected data and current data is the default, these expressions are all equivalent. They access data in the selected rows:

```
dw_1.Object.Data.Selected
dw_1.Object.Data.Primary.Selected
```

Both these expressions access original values for selected rows:

```
dw_1.Object.Data.Original.Selected
```

This example takes the values in the selected rows in dw_2 and populates a DropDownDataWindow in dw_1 with the values, replacing existing data in the DropDownDataWindow. The column with the DropDownDataWindow is called useroptions. The columns of the DataWindow object in dw_2 must match the columns of the DataWindow object for the DropDownDataWindow:

```
dw_1.Object.useroptions.Object.Data = &
   dw_2.Object.Data.Selected
```
CHAPTER 5  
Accessing DataWindow Object Properties in Code

About this chapter
This chapter explains the syntax for constructing expressions that access properties of controls within a DataWindow.

About properties of the DataWindow object and its controls

This section describes:

- What you can do with DataWindow object properties
- Specifying property values in the DataWindow painter
- Accessing DataWindow object property values in code
- Using DataWindow expressions as property values
- Nested strings and special characters for DataWindow object properties
What you can do with DataWindow object properties

The DataWindow object defines the way data is displayed in a DataWindow control. It contains controls that represent the columns, text labels, computed fields, and images.

The properties of the DataWindow object and its controls store the information that specifies the behavior of the DataWindow object. They are not properties of the DataWindow control, but of the DataWindow object displayed in the control.

Terminology

When you are programming for DataWindows, there are several types of expressions involved.

A DataWindow expression is an expression assigned as a value to a DataWindow property and is evaluated by the DataWindow engine. The expression can refer to column data and can have a different value for each row in the DataWindow.

A DataWindow property expression is an expression in your code that gets or sets the value of a DataWindow property. Its effects are equivalent to what the Describe and Modify methods do.

A DataWindow data expression is an expression in your code that gets or sets data in the DataWindow. Its effects are similar to what the SetItem and several GetItem methods do.

Types of values

Property values can be constants or can be DataWindow expressions. DataWindow expressions allow the property value to be based on other conditions in the DataWindow, including data values. Conditional expressions based on data can give the property a different value for each row.

Getting and setting values

You establish initial values for properties in the DataWindow painter. You can also get and set property values at runtime in code.

There are several techniques for accessing property values. A particular property might be accessible by a subset of those techniques. For example, some properties are read-only at runtime, some can be set only at execution, and some accept only constants (not DataWindow expressions) as values.

For a complete list of properties and the ways you can access each one, see Chapter 3, “DataWindow Object Properties.”
Examples: ways of setting the Border property

This table lists the ways you can access a property, using the Border property as an example:

<table>
<thead>
<tr>
<th>What you can do with properties</th>
<th>How to do it, using the Border property as an example</th>
<th>What happens</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set the initial value of the property in the workspace</td>
<td>Property sheet, General tab, Border box</td>
<td>The Border property takes on the value you set unconditionally. In the Preview view and at runtime, the control has the border you indicated in the workspace unless you set the Border property again in some way.</td>
</tr>
<tr>
<td>Specify the value of the property at runtime based on an expression defined for the control in the workspace</td>
<td>Property sheet, General tab, Border box, Expression button</td>
<td>In Preview and at runtime, the border changes as specified in the expression, which overrides the setting on the property sheet. For example, an expression can give the Salary column value a ShadowBox border when the salary exceeds $70,000. To see the effect in the Preview view, you might need to close Preview and reopen it.</td>
</tr>
<tr>
<td>Get the value of the property at runtime in code</td>
<td>Property expression for the Border property or Describe method</td>
<td>Both the expression and the Describe method return the value of the Border property for the specified control.</td>
</tr>
<tr>
<td>Change the value of the property at runtime in code</td>
<td>Property expression for the Border property or Modify method</td>
<td>At runtime, the value of the property changes when the code executes. For example, you could code Modify in the Clicked event and change the border of the control the user clicked.</td>
</tr>
<tr>
<td>Set the initial value of the property at runtime in code for a DataWindow being created</td>
<td>SyntaxFromSQL method</td>
<td>When SyntaxFromSQL executes, the border value of all columns is set in the generated syntax. <strong>PowerBuilder</strong> SyntaxFromSQL is a method of the Transaction object and is described in the <em>PowerScript Reference</em>.</td>
</tr>
</tbody>
</table>

---

*Table 5-1: Ways to access and change DataWindow object properties*
About properties of the DataWindow object and its controls

Specifying property values in the DataWindow painter

When you specify values in the Properties view of the DataWindow painter, you are setting properties of the DataWindow object and its controls.

Each control in the DataWindow (columns, text, drawing controls) has its own property sheets, because there are different sets of properties for each object. To access individual property sheets, display the Properties view and then select a control.

If several controls have the same property and you want them all to have the same value, you can select all the controls so that the property sheet shows the properties they have in common. When you change the property value, it is applied to all selected controls.

For many properties, you can specify a DataWindow expression in the Properties view by clicking the Expression button beside the property. At runtime, the expression is evaluated for each row. When the expression includes row-dependent information in the calculation (such as data), each row can have a different value for the property. In the painter, you can see the results in the Preview view. (You might need to close Preview and reopen it if you are not seeing the settings you have made.)

For information about the components of expressions, see “Using DataWindow expression functions” on page 17 and the Users Guide. For examples of expressions, see “Using DataWindow expressions as property values” on page 443.

Accessing DataWindow object property values in code

There are two ways to access property values in a DataWindow object:

- **Methods**  The Describe and Modify methods use strings to specify the property names. For example:
  
  ```
  dw_1.Describe("empname.Border")
  dw_1.Modify("empname.Border=1")
  ```

- **Expressions**  DataWindow property expressions use the Object property and dot notation. For example:
  
  ```
  dw_1.Object.empname.Border = 1
  li_border = Integer(dw_1.Object.empname.Border)
  ```

  In JavaScript, only the Describe and Modify methods are available.
Which technique to use

The technique you use depends on the type of error checking you want to provide and on whether you know the names of the controls and properties you want to access when the script is compiled.

**Table 5-2: Error handling in DataWindow property expressions**

<table>
<thead>
<tr>
<th>If you want to</th>

<td>return value</td>
</tr>
<tr>
<td>names</td>
<td></td>
</tr>
</tbody>
</table>

**Using DataWindow expressions as property values**

When a DataWindow object property’s value can be an expression, you can make the control’s appearance or other properties depend on other information in the DataWindow.

A DataWindow expression can include:

- Operators
- The names of controls within the DataWindow, especially column and computed field names
- DataWindow expression functions. Some functions, such as IsRowNew, refer to characteristics of an individual row
- User-defined functions

**Different formats for the expression**

When you assign an expression in the painter, you specify just the expression:

```
DataWindowexpression
```

When you assign an expression in code, you specify a default value, a tab, and the expression:

```
defaultvalue [tab] DataWindowexpression
```
About properties of the DataWindow object and its controls

Examples

In the painter  This expression for a column called emp_lname is applied to the Background.Color property. It causes the name’s background to be light gray (15790320) if the current row (person) uses the day care benefit. If not, the background color is set to white:

\[
\text{If(bene_day_care = 'Y', 15790320, 1677215)}
\]

In code  The expression assigned to the Background.Color property includes a default value. Nested quotes complicate the syntax:

**PowerBuilder**

\[
dw_1.Object.emp_lname.Background.Color = "16777215 ~t
\text{If(bene_day_care = 'Y', 15790320, 16777215)}"
\]

**JavaScript**

\[
dw_1.Modify("emp_lname.Background.Color = \"16777215 \t
\text{If(bene_day_care = 'Y', 15790320, 16777215)\")
\]

More examples in the DataWindow painter and in code

These examples illustrate the difference between the format for a DataWindow expression specified in the DataWindow painter versus in code.

**Border property**  The expression applied to the Border property of the salary_plus_benefits column displays a border around salaries over $60,000:

\[
\text{If(salary_plus_benefits > 60000, 1, 0)}
\]

This statement changes the expression in code:

\[
dw_1.Object.salary_plus_benefits.Border = \&
\text{"0 ~t If(salary_plus_benefits > 60000, 1, 0)"}
\]

**Font.Weight property for a column**  To make out-of-state (not in Massachusetts) names and numbers bold in a phone list, apply this expression to the name and phone_number columns. The state column must be part of the data source, but it does not have to be displayed:

\[
\text{If(state = 'MA', 400, 700)}
\]

This statement changes the expression in code:

\[
dw_1.Object.name.Font.Weight = \&
\text{"700 ~t If(state = 'MA', 400, 700)"}
dw_1.Object.phone_number.Font.Weight = \&
\text{"700 ~t If(state = 'MA', 400, 700)"}
\]
CHAPTER 5   Accessing DataWindow Object Properties in Code

**Brush.Color property for a rectangle**  This expression, applied to a rectangle drawn around all the columns in a tabular report, causes alternate rows to be shaded (a graybar effect). Make sure the columns and computed fields have a transparent background. The expression `Mod(GetRow(), 2) = 1` distinguishes odd rows from even rows:

```
If(Mod(GetRow(), 2) = 1, 16777215, 15790320)
```

This statement changes the expression in code:

```
dw_1.Object.rectangle_1.Brush.Color = &
  "0 -t If(Mod(GetRow(), 2) = 1, 16777215, 15790320)"
```

**Brush.Color and Brush.Hatch properties for a rectangle**  To highlight employees whose review date is approaching, draw a rectangle behind the row. This expression for the rectangle’s Brush.Color property makes the rectangle light gray for employees for whom the month of the start date matches the current month or the next month:

```
If(month(start_date) = month(today())
  or month(start_date) = month(today()) + 1
  or (month(today()) = 12 and month(start_date) = 1),
  12632256, 16777215)
```

A similar expression for the Brush.Hatch property makes the fill pattern of the rectangle Bdiagonal (1) for review dates that are approaching. Otherwise, the rectangle is transparent (7) so that it does not show:

```
If(month(start_date) = month(today())
  or month(start_date) = month(today()) + 1
  or (month(today()) = 12 and month(start_date) = 1),
  1, 7)
```

You can also set the Pen.Color and Pen.Style properties to affect the outline of the rectangle.

If you wanted to change the Brush.Color property in code instead of setting it in the painter, the code would look like this:

```
dw_1.Object.rectangle_1.Brush.Color = &
  "'16777215 -t " + &
  "If(month(start_date) = month(today()) " + &
  "or month(start_date) = month(today()) + 1 " + &
  "or (month(today()) = 12 " + &
  "and month(start_date) = 1), 12632256, 16777215)"
```

**Font.Height property for a rectangle**  This expression applied to the Font.Height property of a text control makes the text control in the first row of a DataWindow larger than it appears in other rows. Make sure the borders of the text control are large enough to accommodate the increased size:
About properties of the DataWindow object and its controls

If(GetRow() = 1, 500, 200)

This statement changes the expression for the text control t_desc in code:

\[
\text{dw}_1.\text{Object}.\text{t_desc}.\text{Font.Height} = \&
\text{"200 \text{~If(GetRow() = 1, 500, 200)}"}
\]

For more information

For more information about DataWindow expressions, see Chapter 1, “DataWindow Operators and Expressions.”

Nested strings and special characters for DataWindow object properties

DataWindow property values often involve specifying strings within strings. Embedded quotation marks need special treatment so that the strings are parsed correctly. This treatment varies depending on the programming language you are using.

Table 5-3: Specifying property values in different scripting languages

<table>
<thead>
<tr>
<th>If you are using</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerScript</td>
<td>“Nested strings and special characters for DataWindow object properties” next.</td>
</tr>
<tr>
<td>JavaScript</td>
<td>“Nested strings and special characters in JavaScript for DataWindow object properties” on page 448.</td>
</tr>
</tbody>
</table>

Nested strings and special characters for DataWindow object properties

Tilde (~) is the escape character that allows you to nest quoted strings within other quoted strings and to specify special characters such as tabs and carriage returns. For DataWindow object properties, several levels of nested strings can create a complicated expression.

Techniques for quoting nested strings

Both double and single quotes are valid delimiters for strings. You can use this fact to simplify the specification of nested strings.

There are two ways to embed a string within another string. You can:

- Use the other type of quotation mark for the nested string. If the main string uses double quotes, the nested string can use single quotes.
  
  "If(state='MA',255,0)"

- Use the escape character to specify that a quote is part of the string instead the closure of a previous quote.
  
  "If(state=~"MA~",255,0)"
If the string includes a third level of nested strings, you need to add another tilde which must be accompanied by its own escape character, a second tilde. This is the reason that tildes are usually specified in odd numbers (1, 3, or 5 tildes).

This Modify expression (entered on a single line in code) shows three levels of nested strings:

```javascript
    dw_1.Modify(
        "DataWindow.Color = '255 ~t If(state= 
        -'MA-',255,0)'"
    )
```

This version of the expression has more tildes because there are no single quotes:

```javascript
    dw_1.Modify("DataWindow.Color = ~"255 ~t If(state= 
                    ~~~"MA~~~",255,0)~~")
```

Strings can also include special characters, as shown in the previous example. This table lists the special characters that are most often used in DataWindow expressions.

<table>
<thead>
<tr>
<th>Escape sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>~t</td>
<td>Tab</td>
</tr>
<tr>
<td>~r</td>
<td>Carriage return</td>
</tr>
<tr>
<td>~n</td>
<td>Newline or linefeed</td>
</tr>
<tr>
<td>~&quot;</td>
<td>Double quote</td>
</tr>
<tr>
<td>~'</td>
<td>Single quote</td>
</tr>
<tr>
<td>~~</td>
<td>Tilde</td>
</tr>
</tbody>
</table>

A line break is a carriage return plus a newline (\r\n).

A special case of specifying tildes involves the EditMask.SpinRange property, whose value is two numbers separated by a tilde (not an escape character, simply a tilde). To specify this value in a script, you must use a nested string with four tildes, which is interpreted as a single tilde when parsed:

```javascript
    dw_1.Modify("benefits.EditMask.SpinRange='0~~~~10'\")
```

For more information about nested strings and special characters, see the *PowerScript Reference*.
Nested strings and special characters in JavaScript for DataWindow object properties

Different processing by language and DataWindow

JavaScript uses different characters from those used within the DataWindow to delimit strings and identify special characters. For DataWindow object properties, several levels of nested strings and two types of delimiter can create a complicated expression.

In JavaScript, strings are delimited by double quotes and the escape character in strings is the backslash (\). The escape character allows you to include double quotes and special characters within a string. The DataWindow can use either double or single quotes to delimit strings and uses tilde (~) as an escape character.

Because some parts of the string are parsed by the language and some by the DataWindow, strings passed to the DataWindow often use both types of escape character. The one to use depends on whether the DataWindow or the external language will evaluate the character. The external language deals with the outer string and converts escape sequences to the corresponding special characters. Nested strings are dealt with by the DataWindow parser.

Guidelines

Observe these guidelines for each type of character:

- **Special characters** use the language escape character. Tabs, newlines, and carriage returns are \t, \n, \r

- **Nested double quotes** require the language escape character (\) so they won't be interpreted as the closure of the opening double quote. Depending on the level of nesting, they may also require the DataWindow escape character (~).

- **Single quotes** for nested strings do not need the language escape character, but depending on the level of nesting they may need the DataWindow escape character.

- **Tildes** are specified in odd-numbered groups. They do not interact with the language escape character in counting the number of escape characters used.

Examples

Both of these JavaScript examples are valid ways of nesting a string:

```javascript
dw_1.Modify("DataWindow.Crosstab.Values="empname"");
dw_1.Modify("DataWindow.Crosstab.Values='empname'");
```
The following three JavaScript statements specify the same string. They show a string with three levels of nesting using different combinations of escape characters and quote types. In the first example, note the escaping of the inner quote with a tilde for the DataWindow and a backslash for the language:

```javascript
dw_1.Modify("emp_id.Color="16777215 	 If (emp_status=~"A~",255,16777215)\""");
```

```javascript
dw_1.Modify("emp_id.Color="16777215 \t If (emp_status='A',255,16777215)\""");
```

```javascript
dw_1.Modify("emp_id.Color='16777215 \t If (emp_status="A",255,16777215)\""");
```

The corresponding example in PowerBuilder is:

```powershell
dw_1.Modify("emp_id.Color = ~16777215 ~t If (emp_status=~~~"A~~~",255,16777215)~~")
```

**Special use of tilde**

A special case of specifying tildes involves the EditMask.SpinRange property, whose value is two numbers separated by a tilde (not an escape character, simply a tilde). In code, the value is in a nested string and needs a tilde escape character. The two tildes are interpreted as a single tilde when parsed by the DataWindow:

```powershell
dw_1.modify("benefits.EditMask.SpinRange='0~~10'";
```

**PowerBuilder: Modify and Describe methods for properties**

The following sections provide information about using Modify and Describe methods for DataWindow object properties:

- Advantage and drawbacks of Modify and Describe methods in PowerBuilder
- Handling errors from Modify and Describe methods in PowerBuilder
Advantage and drawbacks of Modify and Describe methods in PowerBuilder

In PowerBuilder, using the Describe and Modify methods to access DataWindow object property values has an advantage and some drawbacks. The examples here use Modify as illustrations, but similar considerations apply to Describe.

**Advantage**

**Allows you to specify column and property names dynamically** In your script, you can build a string that specifies the column and property names.

For example, the following code builds a string in which the default color value and the two color values in the If function are determined in the script. Notice how the single quotes around the expression are included in the first and last pieces of the string:

```powershell
red_amount = Integer(sle_1.Text)
modstring = "emp_id.Color='" + &
            String(RGB(red_amount, 0, 0)) + &
            "-tIf(emp_status='A-'," + &
            String(RGB(255, 0, 0)) + &
            "," + &
            String(RGB(red_amount, 0, 0)) + &
            ")'"
Modify(modstring)
```

The resulting string when red_amount is set to 128 is:

```powershell
emp_id.Color='128~tIf(emp_status='A',255,128)'
```

The following is a simpler example without the If function. You do not need quotes around the value if you are not specifying an expression. Here the String and RGB functions result in a constant value in the resulting modstring:

```powershell
Modify(ls_columnname + ".Color=" + &
      String(RGB(red_amount, 255, 255)))
```

**Drawbacks**

**Setting several properties at once is possible but hard to debug** Although you can set several properties in a single method call, it is harder to understand and debug scripts that do so.

For example, assume the following is entered on a single line in the script editor:

```powershell
rtn = dw_1.Modify("emp_id.Font.Italic=0
                  oval_1.Background.Mode=0
                  oval_1.Background.Color=255")
```
CHAPTER 5 Accessing DataWindow Object Properties in Code

Less efficient than an expression Using a DWObject variable in several property expressions is a little more efficient than setting several properties in a single call to Describe or Modify. However, if you want to be able to name controls dynamically, you might still choose to use Describe or Modify.

For examples of using a DWObject variable, see “Using the DWObject variable in PowerBuilder” on page 454.

Can require complex quoted strings When you specify an expression for a property value, it is difficult to specify nested quotes correctly—the code is hard to understand and prone to error. For Describe, this is less of a drawback—strings do not become as complex because they do not include an expression.

For example, this string entered on a single line in a script assigns a DataWindow expression to the Color property:

```
Modify("emp_id.Color=~"16777215 ~t
If(emp_status==~"A~~~",255,16777215)~")
```

For more information about quoted strings, see “Nested strings and special characters for DataWindow object properties” on page 446.

Handling errors from Modify and Describe methods in PowerBuilder

In PowerBuilder, no runtime error occurs when Describe and Modify try to access invalid controls or properties in the DataWindow object. The validity of the argument string is evaluated before the controls are accessed.

**Modify**

When the string that specifies the control and property to be accessed is invalid, Modify returns an error string, instead of the expected value, such as:

```
Line 1 Column 12: incorrect syntax.
```

You can use the error message to figure out what part of the string is incorrect. This is most useful when you are testing your scripts. The error message, which names the line and column number after which the string was not recognized, might not be helpful after your application is deployed.

**Describe**

When the string for Describe has an unrecognized property, Describe’s return value ends with an exclamation point (!). Describe returns as many values as it recognizes up to the incorrect one.

DataWindow Reference 451
When you specify a valid property but that property doesn’t have a value (either because it hasn’t been set or because its value is an expression that can’t be evaluated), Describe returns a question mark (?) for that property. The property’s actual value is null.

**Always check for errors**
You should include error-checking code that checks for these return values. Other errors can occur later if you depend on settings that failed to take effect.

For more information
For more information on syntax and usage, see Describe and Modify in Chapter 9, “Methods for the DataWindow Control.”

---

**PowerBuilder: DataWindow property expressions**

In PowerBuilder, DataWindow property expressions use dot notation. These sections explain how to use the expressions and what syntax to use to construct them:

- “Basic structure of DataWindows and property expressions in PowerBuilder” on page 453
- “Datatypes of DataWindow property expressions in PowerBuilder” on page 453
- “Using the DWObject variable in PowerBuilder” on page 454
- “When a DataWindow property expression is evaluated in PowerBuilder” on page 458
- “Handling errors from DataWindow property expressions in PowerBuilder” on page 458
- “PowerBuilder syntax for DataWindow property expressions” on page 461
Basic structure of DataWindows and property expressions in PowerBuilder

Controls in a DataWindow

A DataWindow object is made up of many controls (such as Columns, Text, Pictures, and Reports). In PowerBuilder scripts, the datatype of these controls is DWObject. Each DWObject has a set of properties according to its type. The syntax of a property expression allows you to address any of these properties.

Object property

A DataWindow property expression uses the Object property of the DataWindow control to access the DataWindow object. Following the Object property, you specify a control name and one or more properties.

The simple syntax is:

\[ \text{dwcontrol}.\text{Object}.\text{dwcontrolname}.\text{property} \]

For example:

\[ \text{dw_1}.\text{Object}.\text{empname}.\text{Resizeable} \]

For the full syntax, see “PowerBuilder syntax for DataWindow property expressions” on page 461.

About DataWindow data expressions

Expressions that access data in a DataWindow object using dot notation use the Object and Data properties. These expressions are called data expressions (in contrast to property expressions); because of the intricate syntax for data expressions, they are described separately, in Chapter 4, “Accessing Data in Code.”

Datatypes of DataWindow property expressions in PowerBuilder

DataWindow property values

The values of DataWindow object properties are strings. These strings can contain numeric or yes/no values, but the values you access are strings, not integers or boolean values.

Although the property values are really strings, the PowerScript compiler allows you to assign numbers and boolean values to properties whose strings represent numeric values or contain yes/no strings. This does not mean the datatype is integer or boolean. It is just a convenience when assigning a value to the property.
For example, both of these statements are correct:

\[
\begin{align*}
\text{dw}_1.\text{Object.empname.Border} & = 1 \\
\text{dw}_1.\text{Object.empname.Border} & = '1'
\end{align*}
\]

In PowerBuilder, the datatype of a property expression is Any (not string), but the value of the data in the Any variable is a string. This may sound like an unnecessary distinction, but it does matter when you use a property expression as a method argument. If the method does not accept an Any variable as an argument, you might need to use the `String` function to cast the data to the correct datatype.

For example, because the `MessageBox` function accepts a string argument not an Any datatype, the property expression is enclosed in a `String` conversion function:

\[
\text{MessageBox("Border", & String(dw}_1.\text{Object.empname.Border})}
\]

### Using the DWObject variable in PowerBuilder

A PowerBuilder DWObject object is an object that exists within a DataWindow object. Each column, computed field, text control, or drawing control is a DWObject.

A DWObject reference allows you to refer directly to controls within a DataWindow.

You can use a DWObject variable to simplify DataWindow property and data expressions. A DWObject variable takes the place of several elements of the control’s dot notation.

The following syntaxes and examples show how using a DWObject variable affects property and data expressions.

#### Property expressions

The simple syntax for a property expression is:

\[
\text{dwcontrol/Object.dwcontrolname.property}
\]

You can use a DWObject variable to refer to `dwcontrolname`.

If the code declares a DWObject variable and assigns the control within the DataWindow to the variable, using syntax like this:

\[
\text{DWObejct dwobjectvar} \\
\text{dwobjectvar} = \text{dwcontrol/Object.dwcontrolname}
\]
the syntax of the expression itself becomes:

```
dwobjectvar.property
```

For example, if the DataWindow had a column named empname, a text control named t_emplabel, and a computed field named cf_average, you could make the following assignments:

```powerbuilder
DWOObject dwo_column, dwo_text, dwo_compute
dwo_column = dw_1.Object.empname
dwo_text = dw_1.Object.t_emplabel
dwo_compute = dw_1.Object.cf_average
```

### Data expressions

You can use a DWOObject variable to refer to a column in a data expression. For example, this syntax gets data for a single row and column:

```
dwcontrol.Object.columnname.buffer.datasource[ rownum ]
```

If the code declares a DWOObject variable and assigns the control within the DataWindow to the variable, using syntax like this:

```powerbuilder
DWOObject dwobjectvar
dwobjectvar = dwcontrol.Object.columnname
```

The syntax of the expression itself becomes:

```
dwobjectvar.buffer.datasource[ rownum ]
```

### DWOObject variables in PowerBuilder

In PowerBuilder, you can get better performance by using a DWOObject variable to resolve the object reference in a DataWindow property or data expression. Evaluating the reference once and reusing the resolved reference is more efficient than fully specifying the object reference again.

This technique yields the most benefit if your application uses compiled code or if you are using a DataWindow expression in a loop.

For example, this code is not optimized for best performance, because the fully specified data expression within the loop must be resolved during each pass:

```powerbuilder
integer li_data
FOR li_cnt = 1 to 100
    li_data = dw_1.Object.emp_salary[li_cnt]
    .. // Code to process data value
NEXT
```
PowerBuilder: DataWindow property expressions

This code has been optimized. The reference to the control within the DataWindow (emp_salary) is resolved once before the loop begins. The reference stored in the DWObject variable is reused repeatedly in the loop:

```powershell
integer li_data
DWObject dwo_empsalary

dwo_empsalary = dw_1.Object.emp_salary

FOR li_cnt = 1 to 100
    li_data = dwo_empsalary.Primary[li_cnt]
    // Code to process data value
NEXT
```

**PowerBuilder DWObject versus data**

In a data expression for a column that refers to one item, the brackets for the row index identify the expression as a data expression (for information, see “Syntax for one or all data items in a named column” on page 427). However, if you assign the column control to a DWObject variable, the brackets incorrectly signify an array of objects. Therefore you must include a buffer name or data source to specify that you want data:

```powershell
dw_1.Object.emp_salary[1] // Single data item

DWObject dwo_empsalary
dwo_empsalary = dw_1.Object.emp_salary
dwo_empsalary[1] // Incorrect: array of DWObject
dwo_empsalary.Primary[1] // Single data item
```

**DWOObject arguments for DataWindow events in PowerBuilder**

In PowerBuilder, several DataWindow events pass a DWObject argument called dwo to the event script. The value is a resolved reference to a control within the DataWindow having something to do with the user’s action that triggered the event. Often it is the column the user is changing or the control the user clicked.

**What type of DWObject?**

You can use DataWindow properties to find out more about the control stored in dwo. The first step is to find out the control’s type so that subsequent statements will use properties that are appropriate for the control type. If an expression uses a property that does not correspond to the control’s type, it will trigger the Error event. This statement in an event script gets the type:

```powershell
ls_type = dwo.Type
```
The possible values that can be assigned to ls_type are:
- bitmap (for Picture)
- button
- column
- compute (for Computed Field)
- graph
- groupbox
- line
- ole
- ellipse (for Oval)
- rectangle
- roundrectangle
- report
- tableblob
- text
- datawindow (when the user doesn’t click a specific control)

You can write a CHOOSE CASE statement for the expected types.

After you have determined the type, you can get more details about the specific control.

**Examples**

If the control is a column, you can get the column name with this statement:

```plaintext
ls_name = dwo.Name
```

If the control is a column, you can get data from the whole column or from specific rows. You must specify the buffer from which you want to retrieve data. In this statement, row is another argument passed to the event so the value in ls_data is the data in the row and column the user clicked. In this example, if the column value is not a string, an error occurs (check ColType property to get the column datatype):

```plaintext
ls_data = dwo.Primary[row]
```

This statement assigns a new value to the row and column the user clicked. The assignment does not trigger the ItemChanged event and bypasses validation. If the column is not numeric, an error occurs:

```plaintext
dwo.Primary[row] = 41
```

This statement gets all the data in the column the user clicked. The data is stored as an array in the Any variable. An Any variable can hold all datatypes, so no error occurs:

```plaintext
Any la_data
la_data = dwo.datawindow
```
This statement gets data in the column from selected rows. The data is stored as an array in the Any variable:

```powerbuilder
Any la_data
la_data = dwo.Selected
```

**When a DataWindow property expression is evaluated in PowerBuilder**

In PowerBuilder, expressions that refer to DataWindow object properties and data are not verified until your application runs.

**No compiler checking**

When your script is compiled, PowerBuilder does not verify the parameters of the expression that follow the Object property. Your application can select the DataWindow object in a DataWindow control at runtime without invalidating the compiled script.

**Potential execution errors**

If the datatype of the expression is not compatible with how the expression is used, or if the specified rows or columns do not exist, then an error will occur at runtime.

You can handle the error by surrounding the expression in a try-catch block or by writing a script for the DataWindow Error event.

**Handling errors from DataWindow property expressions in PowerBuilder**

**What causes errors**

In PowerBuilder, an invalid DataWindow property expression causes a runtime error in your application. A runtime error causes the application to terminate unless you catch the error in a runtime error handler or unless there is a script for the Error event.

<table>
<thead>
<tr>
<th>Conditions that cause errors</th>
<th>Possible causes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid names of controls within the DataWindow object</td>
<td>Mistyping, which the compiler does not catch because it does not evaluate the expression. A different DataWindow object has been inserted in the control and it has different columns and controls.</td>
</tr>
<tr>
<td>A property is not valid for the specified control</td>
<td>Mistyping. The control is a different type than expected.</td>
</tr>
</tbody>
</table>
You can prevent the application from terminating by handling the error in the DataWindow control’s Error event or by catching the error in a try-catch block. The Error event’s arguments give you several options for responding to the error. You choose a course of action and set the `action` argument to a value of the `ExceptionAction` enumerated datatype.

### ExceptionAction enumerated datatype

If you give the `action` argument a value other than `ExceptionIgnore!`, you will prevent error-handling code in try-catch blocks from executing. For more information on values for the `ExceptionAction` enumerated datatype, see the Error event description in the *PowerScript Reference*.

If you are trying to find out a property value and you know the expression might cause an error, you can include code that prepares for the error by storing a default value in an instance variable. Then the Error event script can return that value in place of the failed expression.

There are three elements to this technique: the declaration of an instance variable, the script that sets the variable’s default value and then accesses a DataWindow property, and the Error event script. These elements are shown in Example 2 below.

### Responding to errors in the Error event script

The error event script:

```power_script
mle_1.text = &
  "error#: " + string(errornumber) + "-r-n" + &
  "text: " + errortext + "-r-n" + &
  "parent: " + errorwindowmenu + "-r-n" + &
  "object: " + errorobject + "-r-n" + &
  "line: " + string(errorline) + "-r-n"
action = ExceptionIgnore!
```

The try-catch block:

```power_script
Try
  ... //DataWindow property expression
Catch (DWRuntimeError myExc)
```

### Responding to errors in a try-catch block

You can prevent the application from terminating by handling the DataWindow runtime error (`DWRuntimeError`) in a try-catch block. If you are trying to find out a property value and you know the expression might cause an error, you can include code that automatically assigns a valid default value that can be substituted for the failed expression, as in Example 2 below.

### Examples

**Example 1**  This code displays complete information about the error in a multilineedit `mle_1`.

The error event script:

```power_script
mle_1.text = &
  "error#: " + string(errornumber) + "-r-n" + &
  "text: " + errortext + "-r-n" + &
  "parent: " + errorwindowmenu + "-r-n" + &
  "object: " + errorobject + "-r-n" + &
  "line: " + string(errorline) + "-r-n"
action = ExceptionIgnore!
```

The try-catch block:

```power_script
Try
  ... //DataWindow property expression
Catch (DWRuntimeError myExc)
```
PowerBuilder: DataWindow property expressions

\[ \text{mle}_1.\text{text} = \& \]
\[ "\text{error\#}: " + \text{string(\text{myExc.number})} + "\text{-r-n}" + \& \]
\[ "\text{text}: " + \text{myExc.text} + "\text{-r-n}" + \& \]
\[ "\text{script}: " + \text{myExc.routinename} + "\text{-r-n}" + \& \]
\[ "\text{object}: " + \text{myExc.objectname} + "\text{-r-n}" + \& \]
\[ "\text{line}: " + \text{string(\text{myExc.line})} + "\text{-r-n}" \]
\[ \text{End Try} \]

If the correct evaluation of the expression is not critical to the application, the application continues without terminating.

Example 2  This example provides a return value that will become the expression’s value if evaluation of the expression causes an error.

There are three elements to code in the error event script. The instance variable is a string:

\[ \text{string is\_dwvalue} \]

This script for a button or other control stores a valid return value in an instance variable and then accesses a DataWindow property:

\[ \text{is\_dwvalue} = "5" \]
\[ \text{ls\_border} = \text{dw\_1.object.id.Border} \]

The Error event script uses the instance variable to provide a valid return value:

\[ \text{action} = \text{ExceptionSubstituteReturnValue!} \]
\[ \text{returnvalue} = \text{is\_dwvalue} \]

The try-catch block:

\[ \text{try} \]
\[ \text{ls\_border} = \text{dw\_1.object.id.Border} \]
\[ \text{catch (DWRuntimeError myDWE\_Error)} \]
\[ \text{ls\_border} = "5" \]
\[ \text{end try} \]

At runtime, if the id column does not exist or some other error occurs, then the expression returns a valid border value—here the string "5". If you are using the Error event instead of a try-catch block, you must first store the value in an instance variable.
PowerBuilder syntax for DataWindow property expressions

The following sections describe syntax for property expressions:

- “Basic syntax for DataWindow property expressions in PowerBuilder” on page 461
- “Syntax for nested objects in DataWindow property expressions in PowerBuilder” on page 464

Basic syntax for DataWindow property expressions in PowerBuilder

**Description**
DataWindow property expressions in PowerBuilder use dot notation to specify the controls and properties that you want to access.

**Syntax**
```
dwcontrol.Object.dwcontrolname { .property } .property { = value }
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set properties.</td>
</tr>
<tr>
<td><code>Object</code></td>
<td>Object indicates that subsequent elements refer to the DataWindow object within <code>dwcontrol</code>.</td>
</tr>
<tr>
<td><code>dwcontrolname</code></td>
<td>A control within the DataWindow object. Possible values are DataWindow (for properties that apply to the whole DataWindow) or the name of a column, computed field, graph, line, oval, picture, rectangle, roundrectangle, report, TableBlob, or text control.</td>
</tr>
</tbody>
</table>

**Nested DataWindow objects**
If `dwcontrolname` is a column with the DropDownDataWindow style, a report, or an OLE Object control, you can specify another Object keyword and `dwcontrolname` to refer to properties of controls within the nested DataWindow object. You can specify `Object.dwobjectname` as many times as needed to refer to a deeply nested report.

For nested syntax, see “Syntax for nested objects in DataWindow property expressions in PowerBuilder” on page 464.
PowerBuilder: DataWindow property expressions

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| property | A property that applies to dwcontrolname. If the property requires additional qualifying properties, list the additional properties, separating them with a dot.  
For lists of applicable properties, see the Property tables at the beginning of Chapter 3, “DataWindow Object Properties.” |

| value | A string whose value is to be assigned to the property.  
If the property value is a number, value can either be a string whose value is a number or a numeric datatype. The value is stored as a string.  
If the property value is a yes or no value, value can be either a string whose value is "yes" or "no" or a boolean value (true or false). The value is stored as "yes" or "no" strings.  
If the property value can be an expression, then value can be a string that takes the form:  
\( \text{defaultvalue}~|t~\text{DataWindowexpression} \)  
where:  
- \( \text{Defaultvalue} \) is any value that is allowed for property.  
- \( \text{DataWindowexpression} \) is an expression that can include names of controls in the DataWindow and DataWindow expression functions.  
- \( \text{Defaultvalue} \) and \( \text{DataWindowexpression} \) are separated by a tab character (~t).  
For examples of DataWindow expressions, see “Using DataWindow expressions as property values” on page 443. |

Datatype  
Any. The datatype of the expression is Any, but actual data is a string.  
For more information about the expression’s datatype, see “Datatypes of DataWindow property expressions in PowerBuilder” on page 453.

Examples  
**Example 1  Boolean property values** In this statement, the boolean value false is stored as the string "no":  
```plaintext
dw_1.Object.DataWindow.ReadOnly = false
```
This statement displays the value of the ReadOnly property (either "yes" or "no") in the StaticText st_status:  
```plaintext
st_status.Text = dw_1.Object.DataWindow.ReadOnly
```
When you test the value of a property in a relational expression, you must compare your test value to the stored values. For ReadOnly, stored values are yes or no, not boolean true or false:

```
IF dw_1.Object.DataWindow.ReadOnly = 'yes' THEN
```

This statement fails because the expression is not boolean:

```
IF dw_1.Object.DataWindow.ReadOnly THEN // Not valid
```

**Example 2** Valid values for the Visible property are 0 and 1. You can set the property to numbers, yes and no, or true and false. Therefore, these three statements are equivalent:

```
dw_1.Object.street.Visible = false
```
```
dw_1.Object.street.Visible = "NO"
```
```
dw_1.Object.street.Visible = 0
```

**Example 3** This example tests whether the X property contains a constant (which can be converted to a number) or a DataWindow expression. The code assigns a default value of 50 to the variable li_x, which remains the value if the property contains an expression the script cannot convert:

```
integer li_x
IF IsNumber( dw_1.Object.id.X ) THEN
    li_x = Integer( dw_1.Object.id.X )
ELSE
    li_x = 50
END IF
```

**Example 4** This script sets the X property to a DataWindow expression. The expression causes IDs with values less than 10 to be indented:

```
string modstring, ls_x
ls_x = "50"
modstring = ls_x + "-t" + &
    "If(id > 10, " + ls_x + "," + &
    String(li_x + 20 ) + ")"
dw_1.Object.id.X = modstring
```

**Example 5** This example makes three columns updatable and reports the value of the Update property in the StaticText st_status. The reported value is “yes,” not true:

```
dw_1.Object.id.Update = true
dw_1.Object.street.Update = true
dw_1.Object.last_name.Update = true
```
PowerBuilder: DataWindow property expressions

Example 6  This example checks whether the id column is set up as a spin control. If so, it sets the spin range to 0 through 10:

```powershell
IF dw_1.Object.id.EditMask.Spin = "yes" THEN
    dw_1.Object.id.EditMask.SpinRange = "0~~~10"
END IF
```

Syntax for nested objects in DataWindow property expressions in PowerBuilder

Description

In PowerBuilder, DataWindow property expressions use additional Object keywords to refer to nested objects. Nested objects include composite or related nested reports and child DataWindows associated with DropDownDataWindow columns. Related nested and composite reports can include their own nested objects. You can extend the dot notation to refer to any level of nesting.

Syntax

```
dwcontrol.Object.nestedcontrolname { [row] } .Object.dwcontrolname.property { .property } { = value }
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the DataWindow control or child DataWindow in which you want to get or set properties.</td>
</tr>
<tr>
<td><code>Object</code></td>
<td>The Object keyword indicates that subsequent elements refer to the DataWindow object within <code>dwcontrol</code>.</td>
</tr>
<tr>
<td><code>nestedcontrolname</code></td>
<td>The name of a DropDownDataWindow column, nested report, or OLE Object control within the DataWindow object in <code>dwcontrol</code>.</td>
</tr>
</tbody>
</table>

About nested reports

A nested report can be one of a group of reports in the Composite presentation style or a nested report included in a base report, which is associated with a specific row.

| `row` | When `nestedcontrolname` is a nested report in a base report, the number of the row the report is associated with. If the report is in a band other than the detail band, it is still associated with a row (see Usage below). |
CHAPTER 5  Accessing DataWindow Object Properties in Code

Datatype

Any. The datatype of the expression is Any, but the actual data is a string.

For more information about the expression’s datatype, see “Datatypes of DataWindow property expressions in PowerBuilder” on page 453.

Usage

A nested report within a base report is usually in the detail band, and each instance of the report is associated with a row. The property expression must include a row number to identify which report to access. If the nested report is in a band other than detail, there may be only one or a few instances of the report, but it is still associated with a row. The expression must include a row number that has an instance of the report.

The following table lists the band and the row that is associated with the report:

<table>
<thead>
<tr>
<th>If the report is in this band</th>
<th>This row is associated with the report</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail</td>
<td>The specified row.</td>
</tr>
<tr>
<td>header</td>
<td>The first row on the page. On screen, this is the first row visible in the DataWindow body.</td>
</tr>
<tr>
<td>footer</td>
<td>The last row on the page. On screen, this is the last row visible in the DataWindow body.</td>
</tr>
</tbody>
</table>

Argument Description

- **dwcontrolname**: The name of a control within the nested DataWindow object. Possible values are DataWindow (for properties that apply to the whole DataWindow) or the name of a Button, Column, Computed field, Graph, GroupBox, Line, Oval, Picture, Rectangle, RoundRectangle, Report, TableBlob, or Text control.
  
  If *dwcontrolname* is a column with the DropDownListDataWindow style, a Report control, or an OLE Object control, you can specify an additional Object keyword and *dwcontrolname* to refer to properties of controls within the nested DataWindow object. You can specify Object.*dwcontrolname* as many times as needed to refer to a control in a deeply nested DataWindow object.

- **property**: A property that applies to *dwcontrolname*. If the property requires additional qualifying properties, list the additional properties, separating them with a dot.
  
  For lists of applicable properties, see the Property tables in Chapter 3, “DataWindow Object Properties”.

- **value**: A string whose value is to be assigned to the property
  
  For more information, see “Basic syntax for DataWindow property expressions in PowerBuilder” on page 461.

DataWindow Reference 465
**PowerBuilder: DataWindow property expressions**

### Examples

#### Example 1
Suppose that a DataWindow has the Composite presentation style and includes a report called `rpt_employee`. The report includes a column `emp_id`. This expression gets the validation expression for the column:

```plaintext
string ls_valid
ls_valid = dw_composite.Object.rpt_employee.&Object.emp_id.Validation
```

#### Example 2
In a Composite DataWindow, one of the reports `rpt_1` has a graph `gr_1`. This example turns on grid lines for the category axis of that graph. The example sets an instance variable to a default value of “not found.” If the expression fails and triggers the Error event, the `ExceptionSubstituteReturnValue!` action causes the text “not found” to be returned so that the second assignment succeeds:

```plaintext
is_dwvalue = "not found"
```

The script for the Error event includes these lines:

```plaintext
action = ExceptionSubstituteReturnValue!
returnvalue = is_dwvalue
```

#### Example 3
Suppose that a DataWindow called `dw_emp` is a base report with employee information. The detail band includes a nested report of salary history called `rpt_salary`. This means there is a separate report with its own properties in each row.

The script checks whether the employee belongs to management (the value in the rank column in the base report is M). If so, the script assigns a DataWindow expression to the Color property of the salary column in the `rpt_salary` nested report. The expression highlights salaries that are over $60,000 in red.
Another statement sets the salary column’s Mode property so the color change will be visible:

```plaintext
integer li_row

FOR li_row = 1 to RowCount()
  IF dw_emp.Object.rank.Primary[li_row] = "M" THEN
    dw_emp.Object.rpt_salary[li_row].Object.&
    salary.Background.Color = &
    '255 -t If(salary > 60000, 255, 0)'
  END IF

END IF
NEXT
```

Example 4 In this example there is a graph in the summary band of a base report called dw_emp. The graph is a nested report called rpt_graph_salaries. Although the graph is not related to a particular row, you still need to provide the row number associated with the summary band when you refer to its properties. This statement turns on autoscaling for the values axis:

```plaintext
dw_emp.Object.rpt_graph_salaries.Object.&
gr_1.Values.AutoScale = 1
```

Example 5 If a column has a DropDownDataWindow edit style, there are properties that affect the column’s appearance. Using nested object syntax, you can also change properties of the child DataWindow for the column. In this example, the DataWindow dw_gift allows a clerk at a nonprofit organization to record donations. The clerk can pick a standard donation amount from a drop-down DataWindow.

This example makes the drop-down DataWindow column called amount a required value and changes the display format for the dollars column in the child DataWindow:

```plaintext
dw_gift.Object.amount.dddw.Required = "Yes"
dw_gift.Object.amount.Object.dollars.Format = "$#,##0"
```
JavaScript: Modify and Describe methods for properties

In JavaScript, you can get and set DataWindow properties with the Describe and Modify methods. Property expressions and DWObject variables are not supported.

These sections describe how to use Modify and Describe in JavaScript:

- “Advantage and drawbacks of the Modify and Describe methods in JavaScript” on page 468
- “Handling errors for Modify and Describe methods in JavaScript” on page 469

Advantage and drawbacks of the Modify and Describe methods in JavaScript

In JavaScript, using the Describe and Modify methods to access DataWindow property values has advantages and drawbacks. The examples here use Modify as illustrations, but similar considerations apply to Describe.

You can specify column and property names dynamically

In your script, you can build a string that specifies the column and property names.

For example, the following code builds a string in which the default color value and the two color values in the If function are determined in the script. Notice how the single quotes around the expression are included in the first and last pieces of the string:

```javascript
red_amount = parseInt(text_1.value);
if (red_amount >= 0 and red_amount < 256) {
    modstring = "emp_id.Color='"
    + text_1.value
    + "\tIf(emp_status='A-',"
    + 255
    + ","
    + text_1.value
    + ")'";
    dw_1.Modify(modstring)
}
```

The resulting string when red_amount is set to 128 is:

```javascript
emp_id.Color='128\tIf(emp_status='A-',255,128)'
```
The following is a simpler example without the If function. The Color property for the column specified in ls_columnname is set to a constant value. You do not need quotes around the value if you are not specifying an expression:

```plaintext
dw_1.Modify(ls_columnname + ".Color=255");
```

**Drawbacks**

**Setting several properties at once is possible but hard to debug**
Although you can set several properties in a single method call, it is harder to understand and debug scripts that do so.

For example, the code for setting three properties is not too complex because there are no nested strings:

```plaintext
rtn = dw_1.Modify("emp_id.Font.Italic=0
oval_1.Background.Mode=0
oval_1.Background.Color=255");
```

**Complex quoted strings are sometimes required**  When you specify an expression for a property value, it is difficult to specify nested quotes correctly—the code is hard to understand and prone to error. For Describe, this is less of a drawback—strings will not become as complex because they do not include an expression.

For example, this string entered on a single line in a script assigns a DataWindow expression to the Color property:

```plaintext
Modify("emp_id.Color="16777215 \t
If(emp_status=~~"A~~",255,16777215)"");
```

For more information about quoted strings, see the *PowerScript Reference*.

**Handling errors for Modify and Describe methods in JavaScript**

In all environments, including JavaScript, no runtime error occurs when Describe and Modify try to access invalid controls or properties in the DataWindow object. The validity of the argument string is evaluated before the controls are accessed.

**Modify**

When the string that specifies the control and property to be accessed is invalid, Modify returns an error string, instead of the expected value, such as:

```
Line 1 Column 12: incorrect syntax.
```

You can use the error message to figure out what part of the string is incorrect. This is most useful when you are testing your scripts. The error message, which names the line and column number after which the string was not recognized, may not be helpful after your application is deployed.
Describe

When the string for Describe has an unrecognized property, Describe’s return value ends with an exclamation point (!). It will return as many values as it recognizes up to the incorrect one.

When you specify a valid property but that property doesn’t have a value (either because it hasn’t been set or because its value is an expression that can’t be evaluated), Describe returns a question mark (?) for that property. The property’s actual value is null.

**Always check for errors**

You should include error-checking code that checks for these return values. Other errors can occur later if you depend on settings that failed to take effect.

For more information

For more information on syntax and usage, see Describe and Modify in Chapter 9, “Methods for the DataWindow Control.”
CHAPTER 6

DataWindow Constants

About this chapter
This chapter lists the PowerBuilder enumerated datatypes that provide constants for setting DataWindow property values.

Contents
<table>
<thead>
<tr>

About DataWindow constants

About constants
This section lists the constants that are defined in the DataWindow control for values of properties and arguments for methods. Constants have both a name and a numeric value.

What values to use

**PowerBuilder**  In PowerBuilder, constants are defined as sets of values associated with enumerated datatypes. Values for enumerated datatypes always end with an exclamation point. When an enumerated datatype is specified as the datatype, you must use the enumerated value. You cannot use the numeric equivalent.

```
dwl.BorderStyle = StyleRaised!
```

**Web DataWindow**  You can use the PowerBuilder enumerated value or an equivalent string value without the exclamation point. Do not use numeric equivalents. This example uses a string value without the exclamation point:

```
dw_1.Band = Detail;
```

**JavaScript**  In JavaScript, you must use the numeric value. The named values are not available.

**DataWindow object properties**  When setting DataWindow properties in PowerBuilder, you use the numeric value in quoted strings.
Alphabetical list of DataWindow constants

This section lists the values according to the PowerBuilder enumerated datatypes, so you can see which values are available for setting a particular type of data. If you know a value’s name but not the enumerated datatype it belongs to, you can find the value in the index of this book.

Alphabetical list of DataWindow constants

This section groups DataWindow constants according to enumerated datatype.

AccessibleRole

Description

Values for specifying the AccessibleRole property for DataWindows and controls in DataWindows.

Values

Use the numeric values with the AccessibleRole DataWindow object property.

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>

Alignment

Description
Values for specifying the alignment of text in DataWindow columns or text controls.

Values
Use the numeric values with the Alignment DataWindow object property.

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left!</td>
<td>0</td>
<td>Text is left aligned.</td>
</tr>
<tr>
<td>Right!</td>
<td>1</td>
<td>Text is right aligned.</td>
</tr>
<tr>
<td>Center!</td>
<td>2</td>
<td>Text is centered.</td>
</tr>
<tr>
<td>Justify!</td>
<td>3</td>
<td>Wrapped text is justified. The last line of text is not stretched to fill the area. So for a single line of text, justified alignment will appear to have no effect.</td>
</tr>
</tbody>
</table>

See also
Alignment

Band

Description
Values identifying the band containing the insertion point in a DataWindow control.

In PowerBuilder, band values are returned by the Position method for a RichTextEdit DataWindow.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>WebDataWindow</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detail!</td>
<td>Detail</td>
<td>0</td>
<td>The detail band</td>
</tr>
<tr>
<td>Header!</td>
<td>Header</td>
<td>1</td>
<td>The header band</td>
</tr>
<tr>
<td>Footer!</td>
<td>Footer</td>
<td>2</td>
<td>The footer band</td>
</tr>
</tbody>
</table>

Web DataWindow
If you are calling the SetPosition method in a server-side Web DataWindow object, you could use a string value for the DataWindow band with or without the exclamation point. For example, you could use Detail or Detail! to specify the detail band.
**Border**

**Description**
Values identifying the border style for a column in a DataWindow.

Used in the `GetBorderStyle` and `SetBorderStyle` methods and the `Border` property for DataWindow columns.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoBorder!</td>
<td>0</td>
<td>No border.</td>
</tr>
<tr>
<td>ShadowBox!</td>
<td>1</td>
<td>Each data value is in a box that has a drop shadow</td>
</tr>
<tr>
<td>Box!</td>
<td>2</td>
<td>Each data value is surrounded by a rectangular border with no shading</td>
</tr>
<tr>
<td>ResizeBorder!</td>
<td>3</td>
<td>The column is resizable; the user can grab the border around any data value and drag it</td>
</tr>
<tr>
<td>Underline!</td>
<td>4</td>
<td>Each data value in the column is underlined</td>
</tr>
<tr>
<td>Lowered!</td>
<td>5</td>
<td>Each data value has a 3D border with shading to make it look lowered</td>
</tr>
<tr>
<td>Raised!</td>
<td>6</td>
<td>Each data value has a 3D border with shading to make it look raised</td>
</tr>
</tbody>
</table>

**See also**

Border
GetBorderStyle
SetBorderStyle

**BorderStyle**

**Description**
Values for specifying the border style of the DataWindow control.

PowerBuilder only. Used for the `Border` property of the DataWindow control.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>StyleBox!</td>
<td>2</td>
<td>The DataWindow control is surrounded by a rectangular box without any shading</td>
</tr>
<tr>
<td>StyleLowered!</td>
<td>5</td>
<td>The control has a 3D border with shading to make it look lowered</td>
</tr>
</tbody>
</table>
### CharSet

**Description**

Values for specifying the character set used in the DataWindow. Generally, the value for CharSet is derived from the font selected for controls within the DataWindow.

Values are used with the Font.CharSet DataWindow object property. Use the numeric values, not the enumerated values, for DataWindow object properties.

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>—</td>
<td>1</td>
<td>The default character set for the specified font</td>
</tr>
<tr>
<td>CharSetAnsi!</td>
<td>0</td>
<td>Standard ANSI</td>
</tr>
<tr>
<td>CharSetUnicode!</td>
<td></td>
<td>Unicode</td>
</tr>
<tr>
<td>CharSetAnsiHebrew!</td>
<td></td>
<td>Right-to-left Hebrew</td>
</tr>
<tr>
<td>CharSetAnsiArabic!</td>
<td></td>
<td>Right-to-left Arabic</td>
</tr>
<tr>
<td>CharSetDBCS-Japanese!</td>
<td></td>
<td>Double-byte Japanese</td>
</tr>
<tr>
<td>—</td>
<td>2</td>
<td>Symbol</td>
</tr>
<tr>
<td>—</td>
<td>128</td>
<td>Shift-JIS</td>
</tr>
<tr>
<td>—</td>
<td>255</td>
<td>OEM</td>
</tr>
</tbody>
</table>

**See also**

Font.property
**DWBuffer**

**Description**

Values for specifying the DataWindow buffer containing the rows you want to access.

Used in many DataWindow methods that access data.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Web DataWindow</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary!</td>
<td>Primary</td>
<td>0</td>
<td>The data in the primary buffer, meaning data that has not been deleted or filtered out. (Default value when argument is optional.)</td>
</tr>
<tr>
<td>Delete!</td>
<td>Delete</td>
<td>1</td>
<td>Data in the delete buffer, meaning data that has been deleted from the DataWindow but has not been committed to the database.</td>
</tr>
<tr>
<td>Filter!</td>
<td>Filter</td>
<td>2</td>
<td>Data in the filter buffer, meaning data that has been removed from view.</td>
</tr>
</tbody>
</table>

**Web DataWindow**

In Web DataWindow methods, you can use a string value with or without the exclamation point for a DataWindow buffer. For example, you could use **Primary** or **Primary!** to specify the primary buffer.

**See also**

GetItemStatus
SetItem
DWConflictResolution

**Description**
Values for specifying how to handle potential conflicts when synchronizing DataWindows in a distributed application.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FailOnAnyConflict!</td>
<td>0</td>
<td>Prevents changes from being synchronized if data in the source DataWindow has changed since its state was captured. (Default value when argument is optional.)</td>
</tr>
<tr>
<td>AllowPartialChanges!</td>
<td>1</td>
<td>Allows changes that are not in conflict to be applied.</td>
</tr>
</tbody>
</table>

**See also**
SetChanges on page 831 explains how to test whether conflicts exist.

DWItemStatus

**Description**
Values for specifying how DataWindow data will be updated in the database.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Web DataWindow</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NotModified!</td>
<td>NotModified</td>
<td>0</td>
<td>The information in the row or column is unchanged from what was retrieved.</td>
</tr>
<tr>
<td>DataModified!</td>
<td>DataModified</td>
<td>1</td>
<td>The information in the column or one of the columns in the row has changed since it was retrieved.</td>
</tr>
<tr>
<td>New!</td>
<td>New</td>
<td>2</td>
<td>The row is new but no values have been specified for its columns. (Applies to rows only, not to individual columns.)</td>
</tr>
</tbody>
</table>
In Web DataWindow methods, you can use a string value with or without the exclamation point for DataWindow status. For example, you could use `DataModified` or `DataModified!` to specify that column or row information has been changed since it was retrieved.

See also

`SetItemStatus` on page 854 describes how to change individual item statuses and how the status affects the SQL statements that update the database.

### FillPattern

**Description**

Values for the fill pattern of shapes (for example, bars or pie slices) in a graph control.

Used in `Get/SetSeriesStyle` and `Get/SetDataStyle` methods for graph controls in a DataWindow or PowerBuilder graph controls.

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Web DataWindow</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solid!</td>
<td>Solid</td>
<td>0</td>
<td>A solid color</td>
</tr>
<tr>
<td>Horizontal!</td>
<td>Horizontal</td>
<td>1</td>
<td>Horizontal lines</td>
</tr>
<tr>
<td>Vertical!</td>
<td>Vertical</td>
<td>2</td>
<td>Vertical lines</td>
</tr>
<tr>
<td>FDiagonal!</td>
<td>FDiagonal</td>
<td>3</td>
<td>Lines from upper left to lower right</td>
</tr>
<tr>
<td>BDiagonal!</td>
<td>BDiagonal</td>
<td>4</td>
<td>Lines from lower left to upper right</td>
</tr>
</tbody>
</table>

PowerBuilder enumerated value | Numeric value | Meaning
-------------------------------|---------------|---------------------------------------|
Foreground!                    | 0             | Text (fill color)                     |
Background!                    | 1             | The background color                  |
Shade!                         | 2             | The shaded area of three-dimensional graphics |
LineColor!                     | 3             | The color of the line                 |
**grDataType**

**Description**
Values for specifying X or Y value when getting information about a scatter graph.

Used in the GetData method for graph controls in a DataWindow or for PowerBuilder graph controls.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>yValue!</td>
<td>1</td>
<td>(Default) The y value of the data point</td>
</tr>
<tr>
<td>xValue!</td>
<td>0</td>
<td>The x value of the data point</td>
</tr>
</tbody>
</table>

GetData

---

**grObjectType**

**Description**
Values that identify parts of a graph.

Used as the return value of the ObjectAtPointer method for graph controls in a DataWindow or for PowerBuilder graph controls.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeGraph!</td>
<td>0</td>
<td>Any place within the graph control that isn’t another grObjectType</td>
</tr>
<tr>
<td>TypeTitle!</td>
<td>4</td>
<td>The title of the graph</td>
</tr>
<tr>
<td>TypeLegend!</td>
<td>8</td>
<td>Within the legend box, but not on a series label</td>
</tr>
<tr>
<td>TypeData!</td>
<td>2</td>
<td>A data point or other data marker</td>
</tr>
<tr>
<td>TypeCategory!</td>
<td>3</td>
<td>A label for a category</td>
</tr>
<tr>
<td>TypeCategoryAxis!</td>
<td>10</td>
<td>The category axis or between the category labels</td>
</tr>
<tr>
<td>TypeCategoryLabel!</td>
<td>6</td>
<td>The label of the category axis</td>
</tr>
<tr>
<td>TypeSeries!</td>
<td>1</td>
<td>The line that connects the data points of a series when the graph’s type is line or on the series label in the legend box</td>
</tr>
<tr>
<td>TypeSeriesAxis!</td>
<td>9</td>
<td>The series axis of a 3D graph</td>
</tr>
</tbody>
</table>
### grSymbolType

**Description**
Values for the symbols associated with data points in a graph.

Used in `Get/SetSeriesStyle` and `Get/SetDataStyle` methods for graph controls in a DataWindow or for PowerBuilder graph controls.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoSymbol!</td>
<td>0</td>
<td>None</td>
</tr>
<tr>

LineStyle

Description
Values for the pattern of lines in a graph.

Used in Get/SetSeriesStyle and Get/SetDataStyle methods for graph controls in a DataWindow or for PowerBuilder graph controls.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Continuous!</td>
<td>0</td>
<td>The line style is a solid line</td>
</tr>
<tr>
<td>Dash!</td>
<td>1</td>
<td>The line style is ----</td>
</tr>
<tr>
<td>DashDot!</td>
<td>2</td>
<td>The line style is -.-.-.</td>
</tr>
<tr>
<td>DashDotDot!</td>
<td>3</td>
<td>The line style is -..-..-..</td>
</tr>
<tr>
<td>Dot!</td>
<td>4</td>
<td>The line style is .....</td>
</tr>
<tr>
<td>Transparent!</td>
<td>5</td>
<td>The line allows the background shapes to show through</td>
</tr>
</tbody>
</table>

MetaDataType

Description
Values that specify whether metadata is saved when XML is exported from a DataWindow object.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNone!</td>
<td>0</td>
<td>Metadata (XML Schema or DTD) is not generated when XML is exported</td>
</tr>
<tr>
<td>XMLSchema!</td>
<td>1</td>
<td>XML Schema is generated when XML is exported</td>
</tr>
<tr>
<td>XMLDTD!</td>
<td>2</td>
<td>DTD is generated when XML is exported</td>
</tr>
</tbody>
</table>

SaveMetaData
RichTextToolbarActivation

Description
Values for specifying when a font toolbar appears for a DataWindow.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>RichTextToolbarActivation Never!</td>
<td>0</td>
<td>Never displays a rich text toolbar.</td>
</tr>
<tr>
<td>RichTextToolbarActivation OnEdit!</td>
<td>1</td>
<td>Displays a rich text toolbar whenever a column with the rich text edit style has focus. This is the default setting.</td>
</tr>
<tr>
<td>RichTextToolbarActivation Always!</td>
<td>2</td>
<td>Displays a rich text toolbar at all times when the DataWindow is visible.</td>
</tr>
</tbody>
</table>

RowFocusInd

Description
Values for specifying the indicator for the current row in a DataWindow. Used in the SetRowFocusIndicator method for DataWindow controls.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Off!</td>
<td>0</td>
<td>There is no indicator for the current row</td>
</tr>
<tr>
<td>FocusRect!</td>
<td>1</td>
<td>The row with focus has a dotted rectangle around it</td>
</tr>
<tr>
<td>Hand!</td>
<td>2</td>
<td>A pointing hand appears in the left margin of the DataWindow beside the row with focus</td>
</tr>
</tbody>
</table>

SetRowFocusIndicator
### SaveAsType

**Description**

Values for specifying a format for data you want to save.

Used in the `SaveAs` method for saving the data of a DataWindow, a graph control in a DataWindow, or a PowerBuilder graph control.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Web DataWindow</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excel!</td>
<td>Excel</td>
<td>0</td>
<td>Microsoft Excel format.</td>
</tr>
<tr>
<td>Text!</td>
<td>Text</td>
<td>1</td>
<td>(Default) Tab-separated columns with a return at the end of each row</td>
</tr>
<tr>
<td>CSV!</td>
<td>CSV</td>
<td>2</td>
<td>Comma-separated values</td>
</tr>
<tr>
<td>SYLK!</td>
<td>SYLK</td>
<td>3</td>
<td>Microsoft Multiplan format</td>
</tr>
<tr>
<td>WKS!</td>
<td>WKS</td>
<td>4</td>
<td>Lotus 1-2-3 format</td>
</tr>
<tr>
<td>WK1!</td>
<td>WK1</td>
<td>5</td>
<td>Lotus 1-2-3 format</td>
</tr>
<tr>
<td>DIF!</td>
<td>DIF</td>
<td>6</td>
<td>Data Interchange Format</td>
</tr>
<tr>
<td>dBASE2!</td>
<td>dBASE2</td>
<td>7</td>
<td>dBASE-II format</td>
</tr>
<tr>
<td>dBASE3!</td>
<td>dBASE3</td>
<td>8</td>
<td>dBASE-III format</td>
</tr>
<tr>
<td>SQLInsert!</td>
<td>SQLInsert</td>
<td>9</td>
<td>SQL syntax</td>
</tr>
<tr>
<td>Clipboard!</td>
<td>Clipboard</td>
<td>10</td>
<td>Save an image of the graph to the clipboard</td>
</tr>
<tr>
<td>PSReport!</td>
<td>PSReport</td>
<td>11</td>
<td>Powersoft Report (PSR) format</td>
</tr>
<tr>
<td>WMF!</td>
<td>WMF</td>
<td>12</td>
<td>Windows Metafile format</td>
</tr>
<tr>
<td>HTMLTable!</td>
<td>HTMLTable</td>
<td>13</td>
<td>HTML TABLE, TR, and TD elements</td>
</tr>
<tr>
<td>Excel5!</td>
<td>Excel5</td>
<td>14</td>
<td>Microsoft Excel Version 5 format</td>
</tr>
<tr>
<td>XML!</td>
<td>XML</td>
<td>15</td>
<td>Extensible Markup Language (XML)</td>
</tr>
<tr>
<td>XSLFO!</td>
<td>XSLFO</td>
<td>16</td>
<td>Extensible Stylesheet Language Formatting Objects (XSL-FO)</td>
</tr>
<tr>
<td>PDF!</td>
<td>PDF</td>
<td>17</td>
<td>Portable Document Format (PDF)</td>
</tr>
<tr>
<td>Excel8!</td>
<td>Excel8</td>
<td>18</td>
<td>Microsoft Excel Version 8 and higher format</td>
</tr>
<tr>
<td>EMF!</td>
<td>EMF</td>
<td>19</td>
<td>Enhanced Metafile Format</td>
</tr>
</tbody>
</table>
Obsolete values
The following SaveAsType values are considered to be obsolete and will be removed in a future release: Excel!, WK1!, WKS!, SYLK!, dBase2!, WMF!. Use Excel8! for current versions of Microsoft Excel! and EMF! in place of WMF!.

Formats supported on UNIX
The following formats are supported in PowerBuilder components deployed to the UNIX platform: Text!, CSV!, SQLInsert!, HTMLTable!, XML!, XSLFO!, and PDF!.

The following formats are not supported on UNIX: PSReport!, Excel!, Excel5!, Excel8!, SYLK!, WKS!, WK1!, DIF!, dBase2!, dBase3!, Clipboard!, WMF! and EMF!.

Web DataWindow server component
The Web DataWindow server component supports all formats listed in the table. In the Web DataWindow server-side SaveAs method, you can use a string value with or without the exclamation point to set the format for the data you want to save. For example, you could use CSV or CSV! to specify a format with comma separated values.

If a destination is not passed in the server-side SaveAs method, a file dialog box will not be put up on the server.

PSR format changed
The format of PSR files created in PowerBuilder has changed in order to improve data integrity for the SaveAsAscii function. As a result, PSR files created in newer builds of PowerBuilder cannot be opened in builds that predate this change. This change was made in PowerBuilder 8.0 build 7063 and PowerBuilder 7.0.3 build 10102.

SaveAs
**SQLPreviewFunction**

**Description**
Values passed to the SQLPreview DataWindow event to indicate what method triggered the event.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PreviewFunction Retrieve!</td>
<td>1</td>
<td>The program called the DataWindow Retrieve method</td>
</tr>
<tr>
<td>PreviewFunction ReselectRow!</td>
<td>2</td>
<td>The program called the DataWindow ReselectRow method</td>
</tr>
<tr>
<td>PreviewFunction Update!</td>
<td>3</td>
<td>The program called the DataWindow Update method</td>
</tr>
</tbody>
</table>

**SaveMetaData**

**Description**
Values that specify how metadata is saved when it is generated with the XML exported from a DataWindow object.

**Values**

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MetaDataInternal!</td>
<td>0</td>
<td>Metadata is saved into the generated XML document or string. To save data using the .Data.XML expression syntax, you must use this value.</td>
</tr>
<tr>
<td>MetaDataExternal!</td>
<td>1</td>
<td>Metadata is saved as an external .xsd or .dtd file (SaveAs method only).</td>
</tr>
</tbody>
</table>

SQLPreviewType

Description
Values passed to the SQLPreview DataWindow event to indicate what SQL statement is being sent to the DBMS.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PreviewSelect!</td>
<td>1</td>
<td>A SELECT statement</td>
</tr>
<tr>
<td>PreviewInsert!</td>
<td>2</td>
<td>An INSERT statement</td>
</tr>
<tr>
<td>PreviewDelete!</td>
<td>3</td>
<td>A DELETE statement</td>
</tr>
<tr>
<td>PreviewUpdate!</td>
<td>4</td>
<td>An UPDATE statement</td>
</tr>
</tbody>
</table>

WebPagingMethod

Description
Values that specify how the Web DataWindow handles paging requests.

Values

<table>
<thead>
<tr>
<th>PowerBuilder enumerated value</th>
<th>Numeric value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Postback!</td>
<td>0</td>
<td>Post back to server to perform paging operations</td>
</tr>
<tr>
<td>Callback!</td>
<td>1</td>
<td>Use script callbacks to retrieve the next page of XML data</td>
</tr>
<tr>
<td>XMLClientside!</td>
<td>2</td>
<td>Retrieve entire result set and use XSLT transformation of cached stylesheet to perform paging operations on the client</td>
</tr>
</tbody>
</table>
WebPagingMethod
CHAPTER 7

Properties of the DataWindow Control and DataStore

About this chapter

The chapter lists the properties of the DataWindow control and DataStore. These properties can be set in code to control the appearance and behavior of the container for the DataWindow object.

In each environment, the DataWindow control and DataStore have properties supported in that environment. Some of the properties are inherited from an ancestor object or superclass and others belong to the DataWindow.

The properties for each environment are listed separately.

Contents

<table>
<thead>
<tr>
<th>Topic</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>Properties for PowerBuilder DataWindow</td>
<td>491</td>
</tr>
<tr>
<td>Properties for the Web DataWindow server component</td>
<td>495</td>
</tr>
<tr>
<td>Properties for the Web ActiveX control</td>
<td>498</td>
</tr>
</tbody>
</table>

Properties for PowerBuilder DataWindow

These properties are also documented in the PowerBuilder book *Objects and Controls*. 
Properties for DataStore objects

You can set properties of a DataStore object in code using dot notation.

Table 7-1: Setting DataStore properties using dot notation

<table>
<thead>
<tr>
<th>DataStore property</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataObject</td>
<td>String</td>
<td>Specifies the name of the DataWindow or Report object associated with the control.</td>
</tr>
<tr>
<td>ClassDefinition</td>
<td>PowerObject</td>
<td>An object of type PowerObject containing information about the class definition of the object or control.</td>
</tr>
<tr>
<td>Object</td>
<td>DWOObject</td>
<td>Used for the direct manipulation of controls within a DataWindow object from a script. These controls could be, for example, columns or text controls. For information, see Chapter 4, “Accessing Data in Code” and Chapter 5, “Accessing DataWindow Object Properties in Code.”</td>
</tr>
</tbody>
</table>

Properties for DataWindow controls

You can set properties of a DataWindow control in the window or user object painter or in code.

Table 7-2: Properties of DataWindow controls

<table>
<thead>
<tr>
<th>DataWindow property</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Border</td>
<td>Boolean</td>
<td>Specifies whether the control has a border. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – Control has a border.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – Control does not have a border.</td>
</tr>
<tr>
<td>BorderStyle</td>
<td>BorderStyle</td>
<td>Specifies the border style of the control. Values are:</td>
</tr>
<tr>
<td></td>
<td>(enumerated)</td>
<td>• StyleBox!</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• StyleLowered!</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• StyleRaised!</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• StyleShadowBox!</td>
</tr>
<tr>
<td>BringToTop</td>
<td>Boolean</td>
<td>Specifies whether PowerBuilder moves the control to the top of the front-to-back order.</td>
</tr>
<tr>
<td>ClassDefinition</td>
<td>PowerObject</td>
<td>An object of type PowerObject containing information about the class definition of the object or control.</td>
</tr>
<tr>
<td>ControlMenu</td>
<td>Boolean</td>
<td>Specifies whether the Control Menu box displays in the control title bar. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – Control Menu box displays in the control title bar.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – Control Menu box does not display in the control title bar.</td>
</tr>
<tr>
<td>DataWindow property</td>
<td>Datatype</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DataObject</td>
<td>String</td>
<td>Specifies the name of the DataWindow object or Report object associated with the control.</td>
</tr>
<tr>
<td>DragAuto</td>
<td>Boolean</td>
<td>Specifies whether PowerBuilder puts the control automatically into Drag Mode. DragAuto has these boolean values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – When the control is clicked, the control is automatically in Drag Mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – When the control is clicked, the control is not automatically in Drag Mode. You have to manually put the control into Drag Mode by using the Drag function.</td>
</tr>
<tr>
<td>DragIcon</td>
<td>String</td>
<td>Specifies the name of the stock icon or the file containing the icon you want to display when the user drags the control (the ICO file).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default icon is a box the size of the control.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the user drags the control, the icon displays when the control is over an area in which the control can be dropped (a valid drop area).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the control is over an area that is not a valid drop area, the No-Drop icon displays.</td>
</tr>
<tr>
<td>Enabled</td>
<td>Boolean</td>
<td>Specifies whether the control is enabled (can be selected). Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – Control is enabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – Control is not enabled.</td>
</tr>
<tr>
<td>Height</td>
<td>Integer</td>
<td>Specifies the height of the DataWindow control, in PowerBuilder units.</td>
</tr>
<tr>
<td>HScrollBar</td>
<td>Boolean</td>
<td>Specifies whether a horizontal scroll bar displays in the control when all the data cannot be displayed at one time. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – Horizontal scroll bar is displayed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – Horizontal scroll bar is not displayed.</td>
</tr>
<tr>
<td>HSpltScroll</td>
<td>Boolean</td>
<td>Specifies whether the split bar displays in the control. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – Split bar is displayed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – Split bar is not displayed.</td>
</tr>
<tr>
<td>Icon</td>
<td>String</td>
<td>Specifies the name of the ICO file that contains the icon that displays when the DataWindow control is minimized.</td>
</tr>
<tr>
<td>LiveScroll</td>
<td>Boolean</td>
<td>Scrolls the rows in the DataWindow control while the user is moving the scroll box.</td>
</tr>
<tr>
<td>MaxBox</td>
<td>Boolean</td>
<td>Specifies whether a Maximize Box displays in the DataWindow control title bar. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• True – Maximize Box displays.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• False – Maximize Box does not display.</td>
</tr>
</tbody>
</table>
### Properties for PowerBuilder DataWindow

<table>
<thead>
<tr>
<th>DataWindow property</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
</table>
| MinBox              | Boolean    | Specifies whether a Minimize Box displays in the DataWindow control title bar. Values are:  
  - True – Minimize Box displays.  
  - False – Minimize Box does not display. |
| Object              | DWOBJect   | Used for the direct manipulation of controls within a DataWindow object from a script. These controls could be, for example, columns or text controls.  
  For information, see Chapter 4, “Accessing Data in Code” and Chapter 5, “Accessing DataWindow Object Properties in Code.” |
| Resizable           | Boolean    | Specifies whether the DataWindow control is resizeable. Values are:  
  - True – DataWindow is resizeable.  
  - False – DataWindow is not resizeable. |
| RightToLeft         | Boolean    | Specifies that characters should be displayed in right-to-left order.  
  The application must be running on a Hebrew or Arabic version of PowerBuilder under an operating system that supports right-to-left display. Values are:  
  - True – Characters display in right-to-left order.  
  - False – Characters display in left-to-right order. |
| TabOrder            | Integer    | Specifies the tab value of the DataWindow control within the window or user object. (0 means the user cannot tab to the control,) |
| Tag                 | String     | Specifies the tag value assigned to the DataWindow control. |
| Title               | String     | Specifies the text that displays in the DataWindow control title bar. |
| TitleBar            | Boolean    | Specifies whether a title bar displays in the DataWindow control.  
  The user can move the DataWindow control only if it has a title bar. Values are:  
  - True – Title bar is displayed in control.  
  - False – No title bar is displayed in control. |
| Visible             | Boolean    | Specifies whether the DataWindow control is visible. Values are:  
  - True – Control is visible.  
  - False – Control is not visible. |
| VScrollBar          | Boolean    | Specifies whether a vertical scroll bar displays in the control when not all the data can be displayed at one time. Values are:  
  - True – Vertical scroll bar is displayed.  
  - False – Vertical scroll bar is not displayed. |
| Width               | Integer    | Specifies the width of the DataWindow control, in PowerBuilder units. |
There are two tables in this section: general properties and database connection properties.

**General properties**

You can set properties of the Web DataWindow server component in EAServer manager. To customize the component, you add as many of the following properties as needed. Some of the properties can also be changed at runtime via server component methods.

For boolean properties, values can be `true` or `false`, or `yes` or `no`.

**Table 7-3: General properties of the Web DataWindow server component**

<table>
<thead>
<tr>
<th>DataWindow property</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Integer</td>
<td>Specifies the X position (the distance from the left edge of the window), in PowerBuilder units.</td>
</tr>
<tr>
<td>Y</td>
<td>Integer</td>
<td>Specifies the Y position (the distance from the top edge of the window), in PowerBuilder units.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>General property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.sybase.datawindow.sourceFileName</td>
<td>Specifies the PBL or PBD that contains the DataWindow object for the component, or the SRD (source definition saved from the Library painter) or PSR (Powersoft Report saved from the DataWindow painter) that is the DataWindow object. See also the SetDWOObject method.</td>
</tr>
<tr>
<td>com.sybase.datawindow.dwObjectName</td>
<td>The name of the DataWindow object in the PBL or PBD specified for sourceFileName. See also the SetDWOObject method.</td>
</tr>
</tbody>
</table>
| com.sybase.datawindow.fixed | Whether component properties can be modified from the server-side script that instantiates the component. Values are:
- Yes – Properties are fixed and cannot be changed. Calling the SetDWOObject, Create, Modify, and SetTrans methods have no effect.
- No – Properties can be changed via the SetDWOObject, Create, Modify, and SetTrans methods. |
### Properties for the Web DataWindow server component

<table>
<thead>
<tr>
<th>General property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.sybase.datawindow.serverServiceClasses</td>
<td>A list of PowerBuilder user objects that are in the PBL or PBD specified in sourceFileName. The class names should be separated by semicolons (;). The user objects implement custom events for data validation. For information on custom events, see the SetServerServiceClasses method.</td>
</tr>
<tr>
<td>com.sybase.datawindow.serverSideState</td>
<td>Specifies whether the server will attempt to maintain its state between method calls. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Yes – The server component will keep the result set and keep the transaction open if possible.</td>
</tr>
<tr>
<td></td>
<td>• No – (Default) The result set is not saved and the server component uses information passed back from the client to retrieve the result set again and remember any uncommitted changes.</td>
</tr>
<tr>
<td>com.sybase.datawindow.trace</td>
<td>Whether calls to component methods are included in the Jaguar server log. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Yes – Calls to component methods are listed in the log.</td>
</tr>
<tr>
<td></td>
<td>• No – Calls to component methods are not logged.</td>
</tr>
<tr>
<td>com.sybase.datawindow.HTMLObjectName</td>
<td>The name used for the Web DataWindow client control in the generated code. The name is used to implement client side events and to allow client side scripting.</td>
</tr>
<tr>
<td></td>
<td>Set this property when there will be more than one Web DataWindow on a Web page so they will not conflict.</td>
</tr>
<tr>
<td></td>
<td>See also the SetHTMLObjectName method.</td>
</tr>
<tr>
<td>com.sybase.datawindow.modifyString</td>
<td>A string that will be used as an argument to the Modify method for setting properties of the DataWindow object. The component calls the Modify method when it is initialized.</td>
</tr>
<tr>
<td></td>
<td>For information on syntax, see the Modify method.</td>
</tr>
</tbody>
</table>
Database connection properties

To use database connection properties, you must add `com.sybase.datawindow.trans.dbms`. This property must be set before other trans properties can be recognized. When `trans.dbms` is set, unspecified connection properties default to an empty string.

Table 7-4: Database connection properties of the Web DataWindow server component

<table>
<thead>
<tr>
<th>Database connection property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>com.sybase.datawindow.trans.dbms</code></td>
<td>A database vendor identifier, as displayed in the PowerBuilder. You must add <code>trans.dbms</code> to enable the rest of the database connection properties. When it is set, any unspecified connection properties default to an empty string. See also the <code>SetTrans</code> method.</td>
</tr>
<tr>
<td><code>com.sybase.datawindow.trans.dbparm</code></td>
<td>DBMS-specific connection parameters. See also the <code>SetTrans</code> method.</td>
</tr>
<tr>
<td><code>com.sybase.datawindow.trans.lock</code></td>
<td>The isolation level. See also the <code>SetTrans</code> method.</td>
</tr>
<tr>
<td><code>com.sybase.datawindow.trans.logid</code></td>
<td>The name or ID of the account the component will use when it logs onto the database server. See also the <code>SetTrans</code> method.</td>
</tr>
<tr>
<td><code>com.sybase.datawindow.trans.logpass</code></td>
<td>The password used to log onto the database server. See also the <code>SetTrans</code> method.</td>
</tr>
<tr>
<td><code>com.sybase.datawindow.trans.database</code></td>
<td>The name of the database to which the component is connecting. Ignored for ODBC. See also the <code>SetTrans</code> method.</td>
</tr>
<tr>
<td><code>com.sybase.datawindow.trans.servername</code></td>
<td>The name of the server on which the database resides. See also the <code>SetTrans</code> method.</td>
</tr>
</tbody>
</table>
Properties for the Web ActiveX control

You can set properties of the Web ActiveX in Param elements on the Web page.

Table 7-5: Properties of the DataWindow Web ActiveX

<table>
<thead>
<tr>
<th>Transaction property</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataWindowObject</td>
<td>Long</td>
<td>The name of the DataWindow object to be displayed in the control. The DataWindow object must be in the file specified in the SourceFileName property.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or The URL for the PSR to be displayed in the Web ActiveX.</td>
</tr>
<tr>
<td>dbParm</td>
<td>String</td>
<td>DBMS-specific parameters. The parameters you include depend on the database driver being used. For example, to use the Sybase JDBC driver (com.sybase.jdb3.jdbc.SybDriver), the parameters are the driver name and the URL of the server. For more information, see the DataWindow Programmers Guide.</td>
</tr>
<tr>
<td>HScrollBar</td>
<td>Boolean</td>
<td>Specifies whether a horizontal scroll bar displays in the control when all the data cannot be displayed at one time. Values are: True – Horizontal scroll bar is displayed. False – Horizontal scroll bar is not displayed.</td>
</tr>
<tr>
<td>HSplitScroll</td>
<td>Boolean</td>
<td>Specifies whether the split bar displays in the control. Values are: True – Split bar is displayed. False – Split bar is not displayed.</td>
</tr>
<tr>
<td>LiveScroll</td>
<td>Boolean</td>
<td>Scrolls the rows in the DataWindow control while the user is moving the scroll box.</td>
</tr>
<tr>
<td>LogID</td>
<td>String</td>
<td>The name or ID of the user who will log on to the server.</td>
</tr>
<tr>
<td>LogPass</td>
<td>String</td>
<td>The password that will be used to log on to the server.</td>
</tr>
<tr>
<td>SourceFileName</td>
<td>Long</td>
<td>The URL or file path for the PowerBuilder library that contains the DataWindow object specified in the DataWindowObject property. The library can be a PBL or a PBD. (The value should be an empty string for a PSR file.) The URL can be an absolute URL or relative to the directory of the HTML document. You can use the BASE HTML element to specify a different base directory.</td>
</tr>
<tr>
<td>SuppressEvents</td>
<td>Boolean</td>
<td>Whether the control will trigger events in response to user actions, such as clicks, and internal actions, such as retrieving data.</td>
</tr>
<tr>
<td>VScrollBar</td>
<td>Boolean</td>
<td>Specifies whether a vertical scroll bar displays in the control when not all the data can be displayed at one time. Values are: True – Vertical scroll bar is displayed. False – Vertical scroll bar is not displayed.</td>
</tr>
</tbody>
</table>
CHAPTER 8

DataWindow Events

About this chapter

This chapter describes what DataWindow objects are and the ways you can use them in various programming environments.

About return values for DataWindow events

The way to specify a return code in a DataWindow event is different in each of the DataWindow environments.

**PowerBuilder**

Use a `RETURN` statement as the last statement in the event script. The datatype of the value is long.

For example, in the ItemChanged event, set the return code to 2 to reject an empty string as a data value:

```csharp
IF data = "" THEN
    RETURN 2
```

**Web DataWindow**

In client events, use a return statement as the last statement in the event script. The datatype of the value is number.

For example, in the ItemChanged event, set the return code to 2 to reject an empty string as a data value:

```javascript
if (newValue = "") {
    return 2;
}
```
Categories of DataWindow events

| Web ActiveX                  | Use the SetActionCode method of the Web ActiveX control. The datatype of the value is number.
|                            | For example, in the DBError event, suppress the standard error message by setting the return code to 1:
|                            |     dw_1.SetActionCode(1); |
| Java                       | Use the setReturnCode method of the event object passed to the event. The datatype of the value is int. The setReturnCode method is inherited from the parent EventData class.
|                            | For example, in the retrieveStart event, prevent the DataWindow from being reset, so that the newly retrieved rows as appended to the rows already retrieved:
|                            |     event.setReturnCode(2); |

Categories of DataWindow events

The reference entries are listed in alphabetical order. To help you find the event you need, the events are organized here by the type of actions that trigger them.

| Changing data             | EditChanged                             |
|                          | ItemChanged                             |
|                          | ItemError                               |
|                          | DropDown for drop-down lists            |
| Database access          | DBError                                 |
|                          | RetrieveStart                           |
|                          | RetrieveRow                             |
|                          | RetrieveEnd                             |
|                          | SQLPreview                              |
|                          | UpdateStart                             |
|                          | UpdateEnd                               |
| Error handling           | DBError                                 |
|                          | Error                                   |
|                          | ItemError                               |
|                          | WSError                                 |
| Focus                    | GetFocus                                |
|                          | LoseFocus                               |

DataWindow event cross-reference

Event names conform to the conventions of each environment. Events for PowerBuilder DataWindow objects and DataStores are listed in *Objects and Controls*. (In online Help, look up DataWindow control or DataStore object, and click the Events button to view these lists.)

The tables in this section list the event names for client-side Web DataWindow objects and for the DataWindow for WebActiveX.

The following table lists event names for the DataWindow for Web ActiveX. It provides correspondences to the standard DataWindow event names that you can use to look up event descriptions and arguments.

<table>
<thead>
<tr>
<th>Web ActiveX event name</th>
<th>See the DataWindow event</th>

### BackTabOut

**Description**

Occurs when the user presses Shift+Tab or, in some edit styles, the left arrow, to move focus to the prior control in the Window or user object.

**PowerBuilder event information**

Event ID: pbm_dwnbacktabout
BackTabOut is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwnbacktabout.

**Web ActiveX event information**
Event Name: onBackTabOut

Return codes
There are no special outcomes for this event. The only code is:
- 0  Continue processing

**ButtonClicked**

**Description**
Occurs when the user clicks a button inside a DataWindow object.

**PowerBuilder event information.**
Event ID: pbm_dwnbuttonclicked

**Argument** | **Description**
--- | ---
row | Long by value. The number of the row the user clicked.
actionreturncode | Long by value. The value returned by the action performed by the button. For information about return values, see the Action DataWindow object property.
dwo | DObject by value. A reference to the control within the DataWindow under the pointer when the user clicked.

**Web DataWindow client control event information**
Event name: ButtonClicked

**Argument** | **Description**
--- | ---
row | Number. The number of the row the user clicked.
objectName | String. The name of the control within the DataWindow under the pointer when the user clicked.

**Web ActiveX event information**
Event name: onButtonClick

**Argument** | **Description**
--- | ---
Row | Number. The number of the row the user clicked.
ReturnCode | Number. The value returned by the action performed by the button. For information about return values, see the Action DataWindow object property.
Return codes
There are no special outcomes for this event. The only code is:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Continue processing</td>
</tr>
</tbody>
</table>

Usage
The ButtonClicked event executes code after the action assigned to the button has occurred.

This event is fired only if you have not selected Suppress Event Processing for the button.

If Suppress Event Processing is on, only the Clicked event and the action assigned to the button are executed when the button is clicked.

If Suppress Event Processing is off, the Clicked event and the ButtonClicked event are fired. If the return code of the ButtonClicking event is 0, the action assigned to the button is executed and the ButtonClicked event is fired. If the return code of the ButtonClicking event is 1, neither the action nor the ButtonClicked event are executed.

Do not use a message box in the Clicked event
If you call the MessageBox function in the Clicked event, the action assigned to the button is executed, but the ButtonClicking and ButtonClicked events are not executed.

Web DataWindow
ButtonClicked fires only for buttons with the UserDefined action. Other buttons cause the page to be reloaded from the server.

Examples
This statement in the ButtonClicked event displays the value returned by the button’s action:

```vbnet
MessageBox(" ", actionreturncode)
```

This statement in the ButtonClicked event displays the value returned by the button’s action:

```vbnet
String ls_Object
String ls_Win

ls_Object = String(dwo.name)
If ls_Object = "cb_close" Then
   Close(Parent)
```

ElseIf ls_Object = "cb_help" Then
    ls_win = parent.ClassName()
    f_open_help(ls_win)
End If

See also ButtonClicking

ButtonClicking

Description
Occurs when the user clicks a button. This event occurs before the ButtonClicked event.

PowerBuilder event information.
Event ID: pbm_dwnbuttonclicking

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row the user clicked.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWObject by value. A reference to the control within the DataWindow under the pointer when the user clicked.</td>
</tr>
</tbody>
</table>

Web DataWindow client control event information
Event name: ButtonClicking

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Number. The number of the row the user clicked.</td>
</tr>
<tr>
<td>objectName</td>
<td>String. The name of the control within the DataWindow under the pointer when the user clicked.</td>
</tr>
</tbody>
</table>

Web ActiveX event information
Event name: beforeButtonClick

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row</td>
<td>Number. The number of the row the user clicked.</td>
</tr>
<tr>
<td>Name</td>
<td>String. The name of the control within the DataWindow under the pointer when the user clicked.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event:

0  Execute the action assigned to the button, then trigger the ButtonClicked event
1  Prevent the action assigned to button from executing and the ButtonClicked event from firing
For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Usage

Use the ButtonClicking event to execute code before the action assigned to the button occurs. If the return code is 0, the action assigned to the button is then executed and the ButtonClicked event is fired. If the return code is 1, the action and the ButtonClicked event are inhibited.

This event is fired only if you have not selected Suppress Event Processing for the button.

The Clicked event is fired before the ButtonClicking event.

Do not use a message box in the Clicked event

If you call the MessageBox function in the Clicked event, the action assigned to the button is executed, but the ButtonClicking and ButtonClicked events are not executed.

Examples

This statement in the ButtonClicking event displays a message box before proceeding with the action assigned to the button:

```plaintext
MessageBox(" ", "Are you sure you want to proceed?")
```

See also

ButtonClicked

**Clicked**

**Description**

Occurs when the user clicks anywhere in a DataWindow control.

**PowerBuilder event information**

Event ID: pbm_dwnlbuttonclk

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpos</td>
<td>Integer by value. The distance of the pointer from the left side of the DataWindow workspace. The distance is given in pixels.</td>
</tr>
<tr>
<td>ypos</td>
<td>Integer by value. The distance of the pointer from the top of the DataWindow workspace. The distance is given in pixels.</td>
</tr>
</tbody>
</table>
Web DataWindow client control event information
Event name: Clicked

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row the user clicked. If the user does not click on a row, the value of the row argument is 0. For example, row is 0 when the user clicks outside the data area, or in the header, summary, or footer area.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWOObject by value. A reference to the control within the DataWindow under the pointer when the user clicked.</td>
</tr>
</tbody>
</table>

Web ActiveX event information
Event name: MouseDown

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| Button   | Number. A value that is the sum of the values of the buttons the user clicked. Values are:  
  • 1 Left button  
  • 2 Right button  
  • 4 Middle button  
  The PowerBuilder Clicked event is always the left mouse button, but in the MouseDown event for the Web ActiveX, you have to check which button was pressed. |
| Shift    | Number. A value that is the sum of the values of the modifier keys the user pressed. Values are:  
  • 1 Shift key  
  • 2 Control key  
  • 4 Alt key  
  The PowerBuilder Clicked event does not provide information about whether a modifier key is pressed, but in the MouseDown event for the Web ActiveX, you can use the Shift argument to check for modifiers. |
| XPos     | Number. The distance of the pointer from the left side of the DataWindow workspace. The distance is given in pixels. |
| YPos     | Number. The distance of the pointer from the top of the DataWindow workspace. The distance is given in pixels. |
CHAPTER 8  DataWindow Events

Return codes

Set the return code to affect the outcome of the event:

- 0 Continue processing
- 1 Prevent the focus from changing

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Usage

The DataWindow Clicked event occurs when the mouse button is pressed down, except in the Web DataWindow (see below).

The dwo, Name, or object argument provides easy access to the control the user clicks within the DataWindow. You do not need to know the coordinates of elements within the DataWindow to program control-specific responses to the user’s clicks. For example, you can prevent editing of a column and use the Clicked script to set data or properties for the column and row the user clicks.

A click can also trigger RowFocusChanged and ItemFocusChanged events. A double-click triggers a Clicked event, then a DoubleClicked event.

For graphs in DataWindow controls, the ObjectAtPointer method provides similar information about objects within the graph control.

PowerBuilder programming note  The xpos and ypos arguments provide the same values the functions PointerX and PointerY return when you call them for the DataWindow control.

Web DataWindow  The Clicked event occurs only in Microsoft Internet Explorer 4 and higher, not in Netscape browsers. When the user clicks on a DataWindow button, the Clicked event occurs before the ButtonClicking event. When the user clicks anywhere else, the Clicked event occurs when the mouse button is released (in other environments, the Clicked event occurs when the button is pressed).

Examples

This code highlights the row the user clicked.

```
This.SelectRow(row, true)
```
If the user clicks on a column heading, this code changes the color of the label and sorts the associated column. The column name is assumed to be the name of the heading text control without _t as a suffix.

```powerbuilder
string ls_name

IF dwo.Type = "text" THEN
    dwo.Color = RGB(255,0,0)
    ls_name = dwo.Name
    ls_name = Left(ls_name, Len(ls_name) - 2)
    This.SetSort(ls_name + ", A")
    This.Sort()
END IF
```

### Collapsed

**Description**

Occurs when a node in a TreeView DataWindow has collapsed.

**PowerBuilder event information**

Event ID: pbm_dwncollapsed

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the first row in the group to be collapsed.</td>
</tr>
<tr>
<td>grouplevel</td>
<td>Long by value. The TreeView level of the group to be collapsed.</td>
</tr>
</tbody>
</table>

**Return codes**

There are no return codes.

**Usage**

A TreeView node collapses when the user clicks the State icon (-) in the TreeView DataWindow or uses any of the Collapse methods.

The Collapsing event occurs before the Collapsed event.
Examples

The following statements in the Collapsed event save the current row and level to instance variables:

```plaintext
ii_level = grouplevel
ii_row = row
```

See also

Collapsing
Expanded

Collapsing

Description

Occurs before a node in a TreeView DataWindow collapses.

**PowerBuilder event information**

Event ID: pbm_dwncollapsing

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the first row in the group to be collapsed.</td>
</tr>
<tr>
<td>grouplevel</td>
<td>Long by value. The TreeView level of the group to be collapsed.</td>
</tr>
</tbody>
</table>

Return codes

Set the return code to affect the outcome of the event. Return 0 to continue processing (collapse the selected node) or return any other value to cancel the collapse.

Usage

A TreeView node collapses when the user clicks the State icon (-) in the TreeView DataWindow or uses any of the Collapse methods.

The Collapsing event occurs before the Collapsed event.

Examples

The following statements in the Collapsing event script display a message box that allows the user to cancel the operation. The message box does not display if the Collapsing event was triggered by the CollapseAll or CollapseLevel methods:

```plaintext
Integer li_ret

if row <>-1 then
    li_ret = MessageBox("Collapsing node", & "Are you sure you want to collapse this node?", & Exclamation!, OKCancel!)
    IF li_ret = 1 then
        return 0
```
**Constructor**

**Description**

Occurs when the DataWindow control or DataStore object is created, just before the Open event for the window that contains the control.

**PowerBuilder event information**

Event ID: pbm_constructor

**Web ActiveX event information**

Event name: onConstructor

**Return codes**

There are no special outcomes for this event. The only code is:

- 0 Continue processing

**Usage**

You can write code for the Constructor event to affect DataWindow properties before it is displayed.

**Examples**

This example retrieves data for the DataWindow dw_1 before its window is displayed:

```powerbuilder
    dw_1.SetTransObject(SQLCA)
    dw_1.Retrieve( )
```

**See also**

Collapsed
Expanding

---

**DBError**

**Description**

Occurs when a database error occurs in the DataWindow or DataStore.

**PowerBuilder event information**

Event ID: pbm_dwndberror
**Web ActiveX event information**

Event name: onDBError

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLDatabaseCode</td>
<td>Number. A database-specific error code.</td>
</tr>
<tr>
<td></td>
<td>See your DBMS documentation for information on the meaning of the code.</td>
</tr>
<tr>
<td></td>
<td>When there is no error code from the DBMS, SQLDatabaseCode contains one of these values:</td>
</tr>
<tr>
<td></td>
<td>-1 – Cannot connect to the database because of missing values in the transaction object.</td>
</tr>
<tr>
<td></td>
<td>-2 – Cannot connect to the database.</td>
</tr>
<tr>
<td></td>
<td>-3 – The key specified in an Update or Retrieve no longer matches an existing row. This can happen when another user has changed the row after you retrieved it.</td>
</tr>
<tr>
<td></td>
<td>-4 – Writing a blob to the database failed.</td>
</tr>
</tbody>
</table>
**DBError**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLSyntax</td>
<td>String. The full text of the SQL statement being sent to the DBMS when the error occurred.</td>
</tr>
<tr>
<td>dwBuffer</td>
<td>Number. The buffer containing the row involved in the database activity that caused the error. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>row</td>
<td>Number. The number of the row involved in the database activity that caused the error (the row being updated, selected, inserted, or deleted).</td>
</tr>
</tbody>
</table>

**Return codes**

Set the return code to affect the outcome of the event:

- **0** Display the error message and trigger the Transaction object’s DBError event if it is defined.
- **1** Do not display the error message, and trigger the Transaction object’s DBError event if it is defined.
- **2** Display the error message and ignore the Transaction object’s DBError event whether it is defined or not.
- **3** Do not display the error message and ignore the Transaction object’s DBError event whether it is defined or not.

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

**Usage**

By default, when the DBError event occurs in a DataWindow control, it displays a system error message. You can display your own message and suppress the system message by specifying a return code of 1 in the DBError event.

Since DataStores are nonvisual, a system message does not display when the DBError event occurs in a DataStore. You must add code to the DBError event to handle the error.

If the row that caused the error is in the Filter buffer, you must unfilter it if you want the user to correct the problem.

**Reported row number**

The row number stored in row is the number of the row in the buffer, not the number the row had when it was retrieved into the DataWindow object.

**Obsolete methods in PowerBuilder** Information formerly provided by the DBErrorCode and DBErrorMessage methods is available in the arguments sqldbcode and sqlerrtext.
Examples

This example illustrates how to display custom error messages for particular database error codes:

```
CHOOSE CASE sqldbcode

    CASE -195 // Required value is NULL.
        MessageBox("Database Problem", &
            "Error inserting row " + string(row) &
            + ". Please specify a value for Employee ID.")
    CASE ...
        // Code to handle other errors

END CHOOSE

RETURN 1 // Do not display system error message
```

See also

Error
ItemError
WSError

Destructor

Description

Occurs when the DataWindow control or DataStore object is destroyed, immediately after the Close event of a window or form.

**PowerBuilder event information**

Event ID: pbmDestructor

**Web ActiveX event information**

Event name: onDestructor

Return codes

There are no special outcomes for this event. The only code is:

- 0  Continue processing

Usage

The Destructor event destroys the DataWindow control or DataStore object and removes it from memory. After it has been destroyed, you can no longer refer to it in other event code. (If you do, a runtime error occurs.)
**Restriction on methods**
Calling a DataStore method that accesses the underlying DataStore internals within this event is not a valid coding practice and can fail silently. Such methods include RowCount, DBCancel, and Modify.

When you issue a DESTROY on a DataStore, the Destructor event is triggered and a Windows WM_DESTROY message is added to the object’s message queue. WM_DESTROY invalidates the memory for the DataStore. If the WM_DESTROY message is handled before the method calls in the Destructor event, methods that attempt to access the destroyed memory fail silently.

Constructor

---

**DoubleClick**

**Description**
Occurs when the user double-clicks in a DataWindow control.

**PowerBuilder event information**
Event ID: pbm_dwnlbuttondblck

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpos</td>
<td>Integer by value. The distance of the pointer from the left side of the DataWindow’s workspace. The distance is given in pixels.</td>
</tr>
<tr>
<td>ypos</td>
<td>Integer by value. The distance of the pointer from the top of the DataWindow’s workspace. The distance is given in pixels.</td>
</tr>
<tr>
<td>row</td>
<td>Long by value. The number of the row the user double-clicked. If the user did not double-click on a row, the value of the row argument is 0. For example, row is 0 when the user double-clicks outside the data area, in text or spaces between rows, or in the header, summary, or footer area.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWOObject by value. A reference to the control within the DataWindow the user double-clicked.</td>
</tr>
</tbody>
</table>
**Web ActiveX event information**

Event name: DblClick

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| Button   | Number. A value that is the sum of the values of the buttons the user clicked. Values are:  
1 Left button  
2 Right button  
4 Middle button  
The PowerBuilder DoubleClicked event is always the left mouse button, but in the MouseUp event for the Web ActiveX, you have to check which button was pressed. |
| XPos     | Number. The distance of the pointer from the left side of the DataWindow’s workspace. The distance is given in pixels. |
| YPos     | Number. The distance of the pointer from the top of the DataWindow’s workspace. The distance is given in pixels. |
| Row      | Number. The number of the row the user double-clicked.  
If the user did not double-click on a row, the value of the Row argument is 0. For example, Row is 0 when the user double-clicks outside the data area, in text or spaces between rows, or in the header, summary, or footer area. |
| Name     | String. The name of the control within the DataWindow that the user double-clicked. |

**Return codes**

There are no special outcomes for this event. The only code is:

0     Continue processing

**Usage**

The dwo, Name, or DWObject argument provides easy access to the control the user clicks. You do not need to know the coordinates of elements within the DataWindow to program control-specific responses to the user’s clicks. For example, you can prevent editing of a column and use the Clicked event to set data or properties for the column and row the user clicks.

*PowerBuilder programming note* The xpos and ypos arguments provide the same values the functions PointerX and PointerY return when you call them for the DataWindow control.
Examples

This example displays a message box reporting the row and column clicked and the position of the pointer relative to the upper-left corner of the DataWindow control:

    string ls_columnname

    IF dwo.Type = "column" THEN
        ls_columnname = dwo.Name
    END IF

    MessageBox("DoubleClicked Event", &
        "Row number: " + row &
        + "-rColumn name: " + ls_columnname &
        + "-rDistance from top of dw: " + ypos &
        + "-rDistance from left side of dw: " + xpos)

### DragDrop

**Description**

**PowerBuilder only** Occurs when the user drags an object onto the control and releases the mouse button to drop the object.

**PowerBuilder event information**

Event ID: pbm_dwdragdrop

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>DragObject by value. A reference to the control being dragged.</td>
</tr>
<tr>
<td>row</td>
<td>Long by value. The number of the row the pointer was over when the user dropped the object. If the pointer was not over a row, the value of the row argument is 0. For example, row is 0 when the pointer is outside the data area, in text or spaces between rows, or in the header, summary, or footer area.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWOObject by value. A reference to the control under the pointer within the DataWindow when the user dropped the object.</td>
</tr>
</tbody>
</table>
Return codes
There are no special outcomes for this event. The only code is:

0  Continue processing

Usage
_Obsolete methods in PowerBuilder_  You no longer need to call the DraggedObject method in a drag event. Use the source argument instead.

Examples
This example for the DragDrop event for a DataWindow checks whether the source object is a DataWindow control. If so, it finds out the current row in the source and moves it to the target:

```powerbuilder
DataWindow ldw_Source

IF source.TypeOf() = DataWindow! THEN
    ldw_Source = source
    IF row > 0 THEN
        ldw_Source.RowsMove(row, row, Primary!, &
            This, 1, Primary!)
    END IF
END IF
```

DragLeave

Description  
**PowerBuilder only**  Occurs when the user is dragging an object and leaves the control.

PowerBuilder event information  
Event ID: pbm_dwndragleave

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>DragObject by value. A reference to the control being dragged.</td>
</tr>
</tbody>
</table>

Return codes  
There are no special outcomes for this event. The only code is:

0  Continue processing

Usage  
*Obsolete methods in PowerBuilder*  You no longer need to call the DraggedObject method in a drag event. Use the source argument instead.

Examples  
This example checks the name of the control being dragged and if it is dw_1, it cancels the drag operation:

```plaintext
IF ClassName(source) = "dw_1" THEN
dw_1.Drag(Cancel!)
END If
```

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>DragObject by value. A reference to the control being dragged.</td>
</tr>
<tr>
<td>row</td>
<td>Long by value. The number of the row the pointer is over. If the pointer is not over a row, the value of the row argument is 0. For example, row is 0 when the pointer is outside the data area, in text or spaces between rows, or in the header, summary, or footer area.</td>
</tr>
</tbody>
</table>
### DropDown

**Description**

Occurs just before the list provided by a DropDownDataWindow is displayed. Use this event to retrieve new data for the child DataWindow.

A DropDownDataWindow is a drop-down choice list whose data is provided by retrieving data for another DataWindow. To create a DropDownDataWindow, you assign the DropDownDataWindow edit style to a column and associate it with another DataWindow that retrieves the data for the choice list.

**PowerBuilder event information**

Event ID: `pbm_dwndropdown`

DropDown is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID `pbm_dwndropdown`.

**Web ActiveX event information**

Event Name: `beforeDropDown`

Return codes

There are no special outcomes for this event. The only code is:

0  Continue processing
**EditChanged**

**Description**

Occurs for each keystroke the user types in an edit control in the DataWindow.

**PowerBuilder event information**

Event ID: pbm_dwnchanging

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row containing the item whose value is being changed.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWObject by value. A reference to the column containing the item whose value is being changed. Dwo is a reference to the column control, not the name of the column.</td>
</tr>
<tr>
<td>data</td>
<td>String by value. The current contents of the DataWindow edit control.</td>
</tr>
</tbody>
</table>

**Web ActiveX event information**

Event name: onEditChange

<table>
<thead>
<tr>

ItemChanged

---

**Error**

**Description**

PowerBuilder  Occurs when an error is found in a data or property expression for an external object or a DataWindow object. Also occurs when a communications error is found in a distributed application.
PowerBuilder event information

Event ID: None

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errornumber</td>
<td>Unsigned integer by value (PowerBuilder’s error number).</td>
</tr>
<tr>
<td>errortext</td>
<td>String, read-only (PowerBuilder’s error message).</td>
</tr>
<tr>
<td>errorwindowmenu</td>
<td>String, read-only. The name of the window or menu that is the parent of the object whose script caused the error.</td>
</tr>
<tr>
<td>errorobject</td>
<td>String, read-only. The name of the object whose script caused the error.</td>
</tr>
<tr>
<td>errorscript</td>
<td>String, read-only. The full text of the script in which the error occurred.</td>
</tr>
<tr>
<td>erroline</td>
<td>Unsigned integer by value. The line in the script where the error occurred.</td>
</tr>
<tr>
<td>action</td>
<td>ExceptionAction by reference.</td>
</tr>
<tr>
<td></td>
<td>A value you specify to control the application’s course of action as a result of the error. Values are:</td>
</tr>
<tr>
<td></td>
<td>• ExceptionFail! – Fail as if this script were not implemented. This is the default action. The error condition triggers the SystemError event if you do not handle the error in a Try-Catch block.</td>
</tr>
<tr>
<td></td>
<td>• ExceptionIgnore! – Ignore this error and return as if no error occurred. Use this option with caution because the conditions that caused the error can cause another error.</td>
</tr>
<tr>
<td></td>
<td>• ExceptionRetry! – Execute the function or evaluate the expression again in case the OLE server was not ready. This option is not valid for DataWindows.</td>
</tr>
<tr>
<td></td>
<td>• ExceptionSubstituteReturnValue! – Use the value specified in the returnvalue argument instead of the value returned by the OLE server or DataWindow and cancel the error condition.</td>
</tr>
<tr>
<td>returnvalue</td>
<td>Any by reference. A value whose datatype matches the expected value that the OLE server or DataWindow would have returned.</td>
</tr>
<tr>
<td></td>
<td>This value is used when the value of action is ExceptionSubstituteReturnValue!.</td>
</tr>
</tbody>
</table>

Return codes
None. (Do not use a RETURN statement.)

Usage
DataWindow and OLE objects are dynamic. Expressions that use dot notation to refer to data and properties of these objects might be valid under some runtime conditions but not others. The Error event allows you to respond to this dynamic situation with error recovery logic.
The Error event also allows you to respond to communications errors in the client component of a distributed application. In the Error event for a custom connection object, you can tell PowerBuilder what action to take when an error occurs during communications between the client and the server.

The Error event gives you an opportunity to substitute a default value when the error is not critical to your application. Its arguments also provide information that is helpful in debugging. For example, the arguments can help you debug DataWindow data expressions that cannot be checked by the compiler—such expressions can only be evaluated at runtime.

**When to substitute a return value**
The ExceptionSubstituteReturnValue! action allows you to substitute a return value when the last element of an expression causes an error. Do not use ExceptionSubstituteReturnValue! to substitute a return value when an element in the middle of an expression causes an error. The substituted return value will not match the datatype of the unresolved object reference and will cause a system error.

The ExceptionSubstituteReturnValue! action is most useful for handling errors in data expressions.

For DataWindows, if an error occurs while evaluating a data or property expression, error processing occurs like this:

1. The Error event occurs.
   - If you use a Try-Catch block, it is best not to script the Error event.
   - If the Error event has no script or its action argument is not changed from the default action (ExceptionFail!), either a catch statement is executed or the SystemError event occurs.
   - If you do not handle the error in a Try-Catch block and the SystemError event has no script, an application error occurs and the application is terminated.

The chapter on “Using DataWindow Objects” in the *DataWindow Programmers Guide* contains a table of correspondences between Error event arguments and DWRuntimeError properties. You can use the DWRuntimeError properties in a Try-Catch block to obtain the same information about an error condition that you would otherwise obtain from Error event arguments.
The error processing in the client component of a distributed application is the same as for DataWindows. For information about handling communications errors in a distributed application, see the discussion of distributed applications in Application Techniques.

For information about error processing in OLE controls, see the ExternalException event description in the PowerScript Reference.

For information about using data and property expressions for DataWindow objects, see Chapter 4, “Accessing Data in Code” and Chapter 5, “Accessing DataWindow Object Properties in Code.”

Examples

This example displays information about the error that occurred and allows the script to continue:

```powerbuilder
MessageBox("Error Number " + string(errornumber) &
    " Occurred", "Errortext: " + String(errortext))
action = ExceptionIgnore!
```

DBError

---

**Expanded**

**Description**

Occurs when a node in a TreeView DataWindow has expanded.

**PowerBuilder event information**

Event ID: pbm_dwnexpanded

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the first row in the group that has been expanded.</td>
</tr>
<tr>
<td>grouplevel</td>
<td>Long by value. The TreeView level of the group that has been expanded.</td>
</tr>
</tbody>
</table>

**Return codes**

There are no return codes.

**Usage**

A TreeView node expands when the user clicks the State icon (+) in the TreeView DataWindow or uses any of the Expand methods.

The Expanding event occurs before the Expanded event.

**Examples**

The following statement writes the TreeView level and row to a single-line edit box when a node is expanded:

```powerbuilder
sle_1.text = "TreeView level: " + string(grouplevel)
sle_1.text += " Row: " + string(row)
```
Expanding

Description
Occurs before a node in a TreeView DataWindow expands.

**PowerBuilder event information**
Event ID: pbm_dwnexpanding

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the first row in the group to be expanded.</td>
</tr>
<tr>
<td>grouplevel</td>
<td>Long by value. The TreeView level of the group to be expanded.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event. Return 0 to continue processing (expand the selected node) or return any other value to cancel the expansion.

Usage
A TreeView node expands when the user clicks the State icon (+) in the TreeView DataWindow or uses any of the Expand methods.

The Expanding event occurs before the Expanded event.

Examples
The following statements in the Expanding event script display a message box that allows the user to cancel the operation:

```powerbuilder
Integer li_ret

li_ret = MessageBox("Expanding node", &
    "Are you sure you want to expand this node?", &
    Exclamation!, OKCancel!)
IF li_ret = 1 then
    return 0
ELSE
    RETURN 1
END IF
```

GetFocus

Description
Occurs just before the control receives focus (before it is selected and becomes active).

**PowerBuilder event information.**
Event ID: pbm_dwnsetfocus

**Web ActiveX event information**
Event name: onGetFocus

Return codes
There are no special outcomes for this event. The only code is:

0  Continue processing

See also
Clicked
LoseFocus

GraphCreate

Description
Occurs after the DataWindow control creates a graph and populates it with data, but before it has displayed the graph. In this event, you can change the appearance of the data about to be displayed.

**PowerBuilder event information**
Event ID: pbm_dwngraphcreate

GraphCreate is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwngraphcreate.

**Web ActiveX Event Information**
Event Name: onGraphCreate

Return codes
There are no special outcomes for this event. The only code is:

0  Continue processing

Examples
The following statement sets to black the foreground (fill) color of the Q1 series in the graph gr_quarter, which is in the DataWindow control dw_report. The statement is in the user event GraphCreate, which is associated with the event ID pbm_dwngraphcreate:

```c
    dw_report.SetSeriesStyle("gr_quarter", "Q1", &foreground!, 0)
```

See also
GetFocus
HTMLContextApplied

Description
Occurs when the SetHTMLAction method has been called to apply an action to a DataWindow control or DataStore. The event occurs after the context has been set but before the action is applied.

**PowerBuilder event information**
Event ID: pbm_dwnhtmlcontextapplied

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>String. A descriptor of the action about to be applied to the DataStore. Action strings include: AppendRow, DeleteRow, InsertRow, PageFirst, PageLast, PageNext, PagePrior, Retrieve, Sort, Update. The list is subject to change and additional actions may be added in the future. Case is not relevant for action values.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event:

- 0  Continue processing (execute the action)
- 1  Prevent the action from being applied

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Usage
Actions include navigating from page to page, inserting and deleting rows, retrieving and updating data. Typically the HTMLContextApplied event is used to call server-side methods for validating data that is about to be updated.

The SetHTMLAction method triggers the HTMLContextApplied event. If the HTMLContextApplied event returns 1, then the SetHTMLAction method returns -4 to indicate that the action was canceled.

See also
SetHTMLAction method
## ItemChanged

**Description**
Occurs when a field in a DataWindow control has been modified and loses focus (for example, the user presses Enter, the Tab key, or an arrow key or clicks the mouse on another field within the DataWindow). It occurs before the change is applied to the item. ItemChanged can also occur when the AcceptText or Update method is called for a DataWindow control or DataStore object.

### PowerBuilder event information
Event ID: pbm_dwnitemchange

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row containing the item whose value is being changed.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWOObject by value. A reference to the column containing the item whose value has been changed. Dwo is a reference to the column control, not the name of the column.</td>
</tr>
<tr>
<td>data</td>
<td>String by value. The new data the user has specified for the item.</td>
</tr>
</tbody>
</table>

### Web DataWindow client control event information
Event name: ItemChanged

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Number. The number of the row containing the item whose value is being changed.</td>
</tr>
<tr>
<td>columnName</td>
<td>String. The name of the column containing the item.</td>
</tr>
<tr>
<td>newValue</td>
<td>String. The new data the user has specified for the item.</td>
</tr>
</tbody>
</table>

### Web ActiveX event information
Event name: beforeItemChange

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row</td>
<td>Number. The number of the row containing the item whose value is being changed.</td>
</tr>
<tr>
<td>Name</td>
<td>String. The name of the column containing the item whose value has been changed.</td>
</tr>
<tr>
<td>Data</td>
<td>String. The new data the user has specified for the item.</td>
</tr>
</tbody>
</table>

### Return codes
Set the return code to affect the outcome of the event:

- **0** (Default) Accept the data value
- **1** Reject the data value and do not allow focus to change
- **2** Reject the data value but allow the focus to change
**ItemError**

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

**Usage**

The ItemChanged event does not occur when the DataWindow control itself loses focus. If the user clicks on an Update or Close button, you will need to write a script that calls AcceptText to see if a changed value should be accepted before the button’s action occurs. For information on the right way to do this, see AcceptText on page 566.

**Obsolete techniques in PowerBuilder**

Information formerly provided by the GetText method is available in the `data` argument.

Instead of calling SetActionCode, use a RETURN statement with a return code.

**Examples**

This example uses the ItemChanged event to provide additional validation; if the column is `emp_name`, it checks that only letters were entered in the column:

```pascal
IF Dwo.name = "Emp_name" THEN
    IF NOT Match(Data, "^[A-Za-z]+$") THEN
        RETURN 2
    END IF
END IF
```

**See also**

ItemError

---

**ItemError**

**Description**

Occurs when a field has been modified, the field loses focus (for example, the user presses Enter, Tab, or an arrow key or clicks the mouse on another field in the DataWindow), and the data in the field does not pass the validation rules for its column. ItemError can also occur when a value imported into a DataWindow control or DataStore does not pass the validation rules for its column.

**PowerBuilder event information**

**Event ID:** pbm_dwnitemvalidationerror

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row containing the item whose new value has failed validation.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWOObject by value. A reference to the column containing the item. Dwo is a reference to the column control, not the name of the column.</td>
</tr>
</tbody>
</table>
CHAPTER 8  DataWindow Events

Web ActiveX event information
Event name: onItemError

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row</td>
<td>Number. The number of the row containing the item whose new value has failed validation.</td>
</tr>
<tr>
<td>Name</td>
<td>String. The name of the column containing the item.</td>
</tr>
<tr>
<td>Data</td>
<td>String. The new data the user specified for the item.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event:

0  (Default) Reject the data value and show an error message box
1  Reject the data value with no message box
2  Accept the data value
3  Reject the data value but allow focus to change

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Usage
If the return code is 0 or 1 (rejecting the data), the field with the incorrect data regains the focus.

The ItemError event occurs instead of the ItemChanged event when the new data value fails a validation rule. You can force the ItemError event to occur by rejecting the value in the ItemChanged event.

Obsolete techniques in PowerBuilder
Information provided by the GetText and GetRow methods is now available in the data and row arguments.

Instead of calling GetColumnName, use the dwo argument and a reference to its Name property.

Instead of calling SetActionCode, use a RETURN statement with the return codes listed above.

Examples
The following excerpt from an ItemError event script of a DataWindow control allows the user to blank out a column and move to the next column. For columns with datatypes other than string, the user cannot leave the value empty (the empty string does not match the datatype). If the user tried to leave the value blank, this code sets the value of the column to a null value of the appropriate datatype.

Argument | Description |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>String by value. The new data the user specified for the item.</td>
</tr>
</tbody>
</table>
string ls_colname, ls_datatype

ls_colname = dwo.Name
ls_datatype = dwo.ColType
// Reject the value if non-blank
IF Trim(data) <> "" THEN
  RETURN 0
END IF

// Set value to null if blank
CHOOSE CASE ls_datatype
  CASE "long"
    integer null_num
    SetNull(null_num)
    This.SetItem(row, ls_colname, null_num)
    RETURN 3
  CASE "date"
    date null_date
    SetNull(null_date)
    This.SetItem(row, ls_colname, null_date)
    RETURN 3
  // Additional cases for other datatypes
END CHOOSE

ItemChanged

ItemFocusChanged
Description
Occurs when the current item in the control changes.

PowerBuilder event information
Event ID: pbm_dwnitemchangefocus

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row containing the item that just gained focus.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWOObject by value. A reference to the column containing the item.</td>
</tr>
</tbody>
</table>

Web DataWindow client control event information
Event name: ItemFocusChanged
CHAPTER 8   DataWindow Events

Web ActiveX event information
Event name: onItemFocusChange

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Number. The number of the row containing the item that just gained focus.</td>
</tr>
<tr>
<td>columnName</td>
<td>String. The name of the column containing the item.</td>
</tr>
</tbody>
</table>

Return codes
There are no special outcomes for this event. The only code is:

0  Continue processing

Usage
ItemFocusChanged occurs when focus is set to another column in the DataWindow, including when the DataWindow is first displayed.

The row and column together uniquely identify an item in the DataWindow.

PowerBuilder programming note  In the ItemFocusChanged event, dwo is always a column control. Therefore, you can get more information about it by examining any properties that are appropriate for columns such as dwo.id and dwo.Name.

Examples
This example reports the row and column that just gained focus and that just lost focus. (The first time the event occurs, there is no item that just lost focus; the script saves the row number and column name in two instance variables called ii_row and is_colname so that the old item is known the next time the event occurs.)

```
IF ii_row > 0 THEN
  sle_olditem.Text = "Old row: " + String(ii_row) & " Old column: " + is_colname
END IF

// Replace values of instance variables
// with info for next change in focus
ii_row = row
is_colname = dwo.Name
```
KeyDown

See also
RowFocusChanged
RowFocusChanging

KeyDown
Description
Occurs for each keystroke when the user is editing in the DataWindow edit control.

PowerBuilder event information
Event ID: pbm_dwnkey

KeyDown is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwnkey.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>Integer by value.</td>
</tr>
</tbody>
</table>
| keyflags | UnsignedLong by value. The modifier keys that are pressed. The keyflags value is the sum of the values for all the pressed keys. Key values are:  
• 1 Shift key  
• 2 Ctrl key  
• 3 Shift + Ctrl keys |

Web ActiveX event information
Event Name: KeyDown

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| Key      | Number. A value that is the sum of the values of the modifier keys the user pressed. Values are:  
• 1 Shift key  
• 2 Ctrl key  
• 4 Alt key |
| Shift    | Number. A value that is the sum of the values of the modifier keys the user pressed. Values are:  
• 1 Shift key  
• 2 Ctrl key  
• 4 Alt key |

Return codes
There are no special outcomes for this event. The only code is:

0    Continue processing
**LoseFocus**

**Description**
Occurs just before a control loses focus (after it becomes inactive).

**PowerBuilder event information**
Event ID: pbm_dwnkillfocus

**Web Activex Event Information**
Event Name: onLoseFocus

**Return codes**
There are no special outcomes for this event. The only code is:

0  Continue processing

**Usage**
Write code for a control’s LoseFocus event if you want some processing to occur when the user changes focus to another control.

*PowerBuilder programming note*  Because the MessageBox function grabs focus, you should not use it when focus is changing, such as in a LoseFocus event. Instead, you might display a message in the window’s title or a MultiLineEdit.

*When to call AcceptText*  You should not call AcceptText in the LoseFocus event or from a user event posted from LoseFocus, unless the DataWindow control no longer has focus. For information about the right way to call AcceptText when the DataWindow control loses focus, see the AcceptText method.

AcceptText method

**MessageText**

**Description**
Occurs when a crosstab DataWindow generates a message. Typical messages are Retrieving data and Building crosstab.

**PowerBuilder event information**
Event ID: pbm_dwnmessageText

MessageText is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwnmessageText.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String by value. The message text.</td>
</tr>
</tbody>
</table>
Web ActiveX Event Information

Event Name: onMessageText

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>String by value. The message text.</td>
</tr>
</tbody>
</table>

Return codes

There are no special outcomes for this event. The only code is:

0  Continue processing

Examples

The following line in the user event for pbm_dwnmessageText displays informational messages as MicroHelp in an MDI application (w_crossstab is an MDI frame window). The informational messages are displayed in the MDI application’s MicroHelp as the crossstab is rebuilt:

```plaintext
w_crossstab.SetMicroHelp(text)
```

See also

GetFocus

MouseMove

Description

Occurs when the user moves the mouse pointer in a DataWindow control.

PowerBuilder event information

Event ID: pbm_dwnmousemove

MouseMove is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user event for the event ID pbm_dwnmousemove.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpos</td>
<td>Integer by value. The distance of the pointer from the left side of the DataWindow’s workspace. The distance is given in pixels.</td>
</tr>
<tr>
<td>ypos</td>
<td>Integer by value. The distance of the pointer from the top of the DataWindow’s workspace. The distance is given in pixels.</td>
</tr>
<tr>
<td>row</td>
<td>Long by value. The number of the row under the pointer. If the pointer is not over a row, the value of the row argument is 0. For example, row is 0 when the user double-clicks outside the data area, in text or spaces between rows, or in the header, summary, or footer area.</td>
</tr>
<tr>
<td>dwo</td>
<td>DWObject by value. A reference to the control within the DataWindow that is under the pointer.</td>
</tr>
</tbody>
</table>
**Web ActiveX event information**

Event name: MouseMove

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| Button   | Number. A value that is the sum of the values of the buttons the user is pressing. Values are:  
- 1 Left button  
- 2 Right button  
- 4 Middle button |
| Shift    | Number. A value that is the sum of the values of the modifier keys the user is pressing. Values are:  
- 1 Shift key  
- 2 Control key  
- 4 Alt key |
| XPos     | Number. The distance of the pointer from the left side of the DataWindow’s workspace. The distance is given in pixels. |
| YPos     | Number. The distance of the pointer from the top of the DataWindow’s workspace. The distance is given in pixels. |

**Return codes**

There are no special outcomes for this event. The only code is:

0  Continue processing

**Usage**

The dwo, Name, or DWObject argument provides easy access to the control the user clicks. You do not need to know the coordinates of elements within the DataWindow to program control-specific responses to the user’s clicks. For example, you can prevent editing of a column and use the Clicked event to set data or properties for the column and row the user clicks.

*PowerBuilder programming note* The xpos and ypos arguments provide the same values the functions PointerX and PointerY return when you call them for the DataWindow control.

CHAPTER 8  DataWindow Events

DataWindow Reference  539

Return codes
There are no special outcomes for this event. The only code is:

0  Continue processing

Usage
The dwo, Name, or DWObject argument provides easy access to the control the user clicks. You do not need to know the coordinates of elements within the DataWindow to program control-specific responses to the user’s clicks. For example, you can prevent editing of a column and use the Clicked event to set data or properties for the column and row the user clicks.

Web ActiveX  For information about the MouseDown event, see the DataWindow Clicked event.

PowerBuilder programming note  The xpos and ypos arguments provide the same values the functions PointerX and PointerY return when you call them for the DataWindow control.

See also
Clicked
DoubleClicked
MouseMove

### OnSubmit

**Description**
This event is triggered just before the Web DataWindow causes a submit.

**Web DataWindow client control event information**
Event name: OnSubmit

**Return codes**
Returning 1 from this event will prevent the submit from occurring.

**Usage**
Use to host multiple DataWindows.

**Examples**
The following client side script transfers the context and action from one DataWindow to the DataWindow being submitted.

```javascript
<SCRIPT>
function dw_first_OnSubmit()
```

DataWindow Reference  539
To enable the second DataWindow to create the required fields on the submit form, each of the DataWindows must have two arguments defined in the SelfLinkArgs property:

- dw_first must have dw_second_context and dw_second_action defined
- dw_second must have dw_first_context and dw_first_action defined

---

**Printend**

**Description**

Occurs when the printing of a DataWindow or DataStore ends.

**PowerBuilder event information**

Event ID: pbm_dwnprintend

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pagesprinted</td>
<td>Long by value. The total number of pages that were printed.</td>
</tr>
</tbody>
</table>

**Web ActiveX event information**

Event name: afterPrint

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PagesPrinted</td>
<td>Number. The total number of pages that were printed.</td>
</tr>
</tbody>
</table>

**Return codes**

There are no special outcomes for this event. The only code is:

0  Continue processing
Examples

This statement displays the number of pages that were printed after the Print method was called to print the contents of the DataWindow control:

```plaintext
st_1.Text = String(pagesprinted) &
    + " page(s) have been printed."
```

See also

PrintMarginChange
PrintPage
PrintStart

**PrintMarginChange**

Description

Occurs when the print margins of the DataWindow change.

**PowerBuilder event information**

Event ID: pbm_dwnprintmarginchange

PrintMarginChange is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwnprintmarginchange.

**Web ActiveX event information**

Event Name: onPrintMarginChange

Return codes

There are no special outcomes for this event. The only code is:

- 0  Continue processing

See also

Printend
PrintPage
PrintStart

**PrintPage**

Description

Occurs before each page of the DataWindow or DataStore is formatted for printing.

**PowerBuilder event information**

Event ID: pbm_dwnprintpage

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pagenumber</td>
<td>Long by value. The number of the page about to be printed.</td>
</tr>
<tr>
<td>copy</td>
<td>Long by value. The number of the copy being printed.</td>
</tr>
</tbody>
</table>
PrintPage

Web ActiveX event information
Event name: beforePrintPage

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageNumber</td>
<td>Number. The number of the page about to be printed.</td>
</tr>
<tr>
<td>Copy</td>
<td>Number. The number of the copy being printed.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event:

0  Do not skip the page
1  Skip the page

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Examples
After a script prints a DataWindow control, you can limit the number of pages to be printed by suppressing every page after page 50.

This statement in a CommandButton’s Clicked event script prints the contents of the DataWindow control:

dw_1.Print()

This code in the PrintPage event of dw_1 cancels printing after reaching page 50:

IF pagenumber > 50 THEN This.PrintCancel()

If you know every fifth page of the DataWindow contains the summary information you want, you can suppress the other pages with some arithmetic and a RETURN statement:

IF Mod(pagenumber / 5) = 0 THEN
  RETURN 0
ELSE
  RETURN 1
END IF

Printend
PrintMarginChange
PrintStart
PrintStart

Description
Occurs when the printing of the DataWindow or DataStore starts.

**PowerBuilder event information**
Event ID: pbm_dwnprintstart

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pagesMax</td>
<td>Long by value. The total number of pages that will be printed, unless pages are skipped.</td>
</tr>
</tbody>
</table>

**Web ActiveX event information**
Event name: beforePrintPage

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PagesMax</td>
<td>Number. The total number of pages that will be printed, unless pages are skipped.</td>
</tr>
</tbody>
</table>

Return codes
There are no special outcomes for this event. The only code is:
0 Continue processing

Usage
To skip printing some of the pages in the DataWindow or DataStore, write code for the PrintPage event.

PrintEnd
PrintMarginChange
PrintPage

ProcessEnter

Description
Occurs when the user presses the Enter key when focus is in the DataWindow or the DataWindow’s edit control.

**PowerBuilder event information**
Event ID: pbm_dwnprocessenter

ProcessEnter is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwnprocessenter.

**Web ActiveX event information**
Event Name: beforeEnter

Return codes
There are no special outcomes for this event. The only code is:
0 Continue processing
**RButtonDown**

**Description**  
Occurs when the right mouse button is pressed on the DataWindow control.

**PowerBuilder event information**  
Event ID: pbm_dwnrbuttondown

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| **flags** | UnsignedLong by value. The modifier keys and mouse buttons that are pressed. The flags value is the sum of the values for all the pressed keys and buttons.  
Key and button values are:  
• 1 – Left mouse button  
• 2 – Right mouse button  
• 4 – Shift key  
• 8 – Ctrl key  
• 16 – Middle mouse button  
In the RButtonDown event, the right mouse button is always pressed, so 2 is always summed in the value of flags.  
For information on evaluating the flags value, see Syntax 2 of MouseMove in the PowerScript Reference. |
| **xpos** | Integer by value. The distance of the pointer from the left edge of the window’s workspace in pixels. |
| **ypos** | Integer by value. The distance of the pointer from the top of the window’s workspace in pixels. |

**Web ActiveX event information**  
Event name: MouseDown

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Button** | Number. A value that is the sum of the values of the buttons the user clicked. Values are:  
• 1 – Left button  
• 2 – Right button  
• 4 – Middle button  
The PowerBuilder RButtonDown event is always the right mouse button, but in the MouseDown event for the Web ActiveX, you have to check which button was pressed. |
### DataWindow Events

**Return codes**

There are no special outcomes for this event. The only code is:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Continue processing</td>
</tr>
</tbody>
</table>

## Resize

**Description**

Occurs when the user or a script opens or resizes the client area of a DataWindow control.

**PowerBuilder event information**

Event ID: pbm_dwnresize
Resize

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sizetype</td>
<td>UnsignedLong by value.</td>
</tr>
<tr>
<td></td>
<td>• 0 – (SIZE_RESTORED) The DataWindow has been resized, but it was not minimized or maximized. The user may have dragged the borders or a script may have called the Resize method.</td>
</tr>
<tr>
<td></td>
<td>• 1 – (SIZE_MINIMIZED) The DataWindow has been minimized.</td>
</tr>
<tr>
<td></td>
<td>• 2 – (SIZE_MAXIMIZED) The DataWindow has been maximized.</td>
</tr>
<tr>
<td>newwidth</td>
<td>Integer by value. The width of the client area of the DataWindow control in pixels.</td>
</tr>
<tr>
<td>newheight</td>
<td>Integer by value. The height of the client area of the DataWindow control in pixels.</td>
</tr>
</tbody>
</table>

**Web ActiveX event information**

Event name: onResize

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SizeType</td>
<td>Number.</td>
</tr>
<tr>
<td></td>
<td>• 0 – (SIZE_RESTORED) The DataWindow has been resized, but it was not minimized or maximized. The user may have dragged the borders or a script may have called the Resize method.</td>
</tr>
<tr>
<td></td>
<td>• 1 – (SIZE_MINIMIZED) The DataWindow has been minimized.</td>
</tr>
<tr>
<td></td>
<td>• 2 – (SIZE_MAXIMIZED) The DataWindow has been maximized.</td>
</tr>
<tr>
<td>NewWidth</td>
<td>Number. The width of the client area of the DataWindow control in pixels.</td>
</tr>
<tr>
<td>NewHeight</td>
<td>Number. The height of the client area of the DataWindow control in pixels.</td>
</tr>
</tbody>
</table>

**Return codes**

There are no special outcomes for this event. The only code is:

0  Continue processing
CHAPTER 8    DataWindow Events

RetrieveEnd
Description
Occurs when the retrieval for the DataWindow or DataStore is complete.

PowerBuilder event information
Event ID: pbm_dwnretrieveend

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowcount</td>
<td>Long by value. The number of rows that were retrieved.</td>
</tr>
</tbody>
</table>

Web ActiveX event information
Event name: afterRetrieve

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RowCount</td>
<td>Number. The number of rows that were retrieved.</td>
</tr>
</tbody>
</table>

Return codes
There are no special outcomes for this event. The only code is:

0  Continue processing

Usage
The number of rows retrieved in the rowcount argument is an unfiltered value.

Examples
This message box displayed in the RetrieveEnd event script tells the user the number of rows just retrieved:

```
MessageBox("Total rows retrieved", String(rowcount))
```

See also
RetrieveRow
RetrieveStart
SQLPreview
UpdateStart

RetrieveRow
Description
Occurs after a row has been retrieved.

PowerBuilder event information
Event ID: pbm_dwnretrieverow

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the row that was just retrieved</td>
</tr>
</tbody>
</table>

Web ActiveX event information
Event name: onRetrieveRow
**RetrieveStart**

**Argument** | **Description**  
---|---  
Row | Number. The number of the row that was just retrieved

**Return codes**

Set the return code to affect the outcome of the event:

- **0** Continue processing
- **1** Stop the retrieval

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

**Usage**

If you want to guard against potentially large queries, you can have code in the RetrieveRow event check the row argument and decide whether the user has reached a maximum limit. When row exceeds the limit, you can return 1 to abort the retrieval (in which case the retrieval cannot be resumed).

A script in the RetrieveRow event (even a comment) can significantly increase the time it takes to complete a query.

**Obsolete methods in PowerBuilder** Instead of calling `SetActionCode`, use the `RETURN` statement with a return code instead.

**Examples**

This code for the RetrieveRow event aborts the retrieval after 250 rows have been retrieved.

```powerbuilder
IF ll_row > 250 THEN
    MessageBox("Retrieval Halted", &
        "You have retrieved 250 rows, the allowed &
        maximum.")
    RETURN 1
ELSE
    RETURN 0
END IF
```

**See also**

RetrieveEnd  
RetrieveStart  
SQLPreview  
UpdateStart

---

**RetrieveStart**

**Description**

Occurs when the retrieval for the DataWindow or DataStore is about to begin.

**PowerBuilder event information**

Event ID: pbm_dwnretrievestart
Web ActiveX event information

Event name: beforeRetrieve

Return codes

Set the return code to affect the outcome of the event:

- 0  Continue processing
- 1  Do not perform the retrieval
- 2  Do not reset the rows and buffers before retrieving data

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Usage

A return code of 2 prevents previously retrieved data from being cleared, allowing the current retrieval process to append new rows to the old data.

Obsolete methods in PowerBuilder

Instead of calling SetActionCode, use the RETURN statement with a return code instead.

Examples

This statement in the RetrieveStart event prevents a reset from taking place (rows will be added to the end of the previously retrieved rows):

```
RETURN 2
```

This statement in the RetrieveStart event aborts the retrieval:

```
RETURN 1
```

This code allows rows to be retrieved only when a user has an ID between 101 and 200 inclusive (the ID was stored in the instance variable il_id_number when the user started the application); all other IDs cannot retrieve rows:

```
CHOOSE CASE il_id_number
    CASE IS < 100
        RETURN 1
    CASE 101 to 200
        RETURN 0
    CASE IS > 200
        RETURN 1
END CHOOSE
```

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentrow</td>
<td>Long by value. The number of the row that has just become current.</td>
</tr>
</tbody>
</table>

Web ActiveX event information

Event name: beforeRowFocusChange

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newRow</td>
<td>Number. The number of the row that has just become current.</td>
</tr>
</tbody>
</table>

Return codes

There are no special outcomes for this event. The only code is:

0 Continue processing

Usage

The SetRow method, as well as user actions, can trigger the RowFocusChanged and ItemFocusChanged events.
In a read-only DataWindow, when you click on any column that is not in the current row, the RowFocusChanging and RowFocusChanged events fire, but the current column is not changed—the current column remains at 0, since no column can have focus. DataWindows are read-only if updates are not allowed, all tab orders are set to 0, or all tab columns are protected.

If, however, focus is on an editable column in an updatable DataWindow (a DataWindow that has one or more editable columns), the row focus events do not fire when you click on a protected column or on a column whose tab order is 0. The focus remains on the current, editable column.

If focus moves off an editable column in an updatable DataWindow, the DataWindow switches to read-only mode. This can happen when the last row in the DataWindow does not have an editable column. In this case, tabbing off the last editable column causes the row focus to move to the row following the row with the last editable column. The DataWindow then remains in read-only mode until focus is given to an editable column.

When you use the ScrollToRow method to change focus, the RowFocusChanging event is triggered before the scroll occurs, and the RowFocusChanged event is triggered after the scroll occurs.

**Examples**

This example displays the current row number and the total number of rows in a SingleLineEdit:

```powerbuilder
sle_1.Text = "Row " + String(currentrow) &
+ " of " + String(This.RowCount())
```

**See also**

ItemFocusChanged
RowFocusChanging

---

**RowFocusChanging**

**Description**

Occurs when the current row is about to change in the DataWindow. (The current row of the DataWindow is not necessarily the same as the current row in the database.)

The RowFocusChanging event occurs just before the RowFocusChanged event.

**PowerBuilder event information**

Event ID: pbm_dwnrowchanging
Web DataWindow client control event information
Event name: RowFocusChanging

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentrow</td>
<td>Long by value. The number of the row that is current (before the row is deleted or its number changes). If the DataWindow object is empty, currentrow is 0 to indicate there is no current row.</td>
</tr>
<tr>
<td>newRow</td>
<td>Long by value. The number of the row that is about to become current. If the new row is going to be an inserted row, newRow is 0 to indicate that it does not exist.</td>
</tr>
</tbody>
</table>

Web ActiveX event information
Event name: beforeRowFocusChange

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CurrentRow</td>
<td>Number. The number of the row that is current (before the row is deleted or its number changes). If the DataWindow object is empty, CurrentRow is 0 to indicate there is no current row.</td>
</tr>
<tr>
<td>NewRow</td>
<td>Number. The number of the row that is about to become current. If the new row is going to be an inserted row, NewRow is 0 to indicate that it does not exist.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event:

0  Continue processing (setting the current row)
1  Prevent the current row from changing

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.
RowFocusChanging

Usage

Typically the RowFocusChanging event is coded to respond to a mouse click or keyboard action that would change the current row in the DataWindow object. The following methods can also trigger the RowFocusChanging event, as well as the RowFocusChanged and ItemFocusChanged events, when the action changes the current row:

- SetRow
- Retrieve
- RowsCopy
- RowsMove
- DeleteRow
- RowsDiscard

In these cases, the RowFocusChanging event script can prevent the changing of the DataWindow object’s current row only. The script cannot prevent the data from being changed (for example, the rows still get moved).

When you use the ScrollToRow method to change focus, the RowFocusChanging event is triggered before the scroll occurs, and the RowFocusChanged event is triggered after the scroll occurs.

In a tabular DataWindow, if the user clicks to change rows, the row focus does not change, and the row and DataWindow do not scroll. You can still scroll programmatically or by using the scroll bar.

In a read-only DataWindow, when you click on any column that is not in the current row, the RowFocusChanging and RowFocusChanged events fire, but the current column is not changed—the current column remains at 0, since no column can have focus. DataWindows are read-only if updates are not allowed, all tab orders are set to 0, or all tab columns are protected.

However, if focus is on an editable column in an updatable DataWindow (a DataWindow that has one or more editable columns), the row focus events do not fire when you click on a protected column or on a column whose tab order is 0. The focus remains on the current, editable column.

If focus moves off an editable column in an updatable DataWindow, the DataWindow switches to read-only mode. This can happen when the last row in the DataWindow does not have an editable column. In this case, tabbing off the last editable column causes the row focus to move to the row following the row with the last editable column. The DataWindow then remains in read-only mode until focus is given to an editable column.

Examples

This example displays a message alerting you that changes have been made in the window dw_detail which will be lost if the row focus is changed to the window dw_master.
IF dw_detail.DeletedCount() > 0 OR &
    dw_detail.ModifiedCount() > 0 THEN
    MessageBox("dw_master", "Changes will be lost & in Detail")
ELSE
    RETURN 0
END IF

See also
ItemFocusChanged
RowFocusChanged

ScrollHorizontal

Description
Occurs when user scrolls left or right in the DataWindow with the TAB or arrow keys or the scroll bar.

PowerBuilder event information
Event ID: pbm_dwnhscroll

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scrollpos</td>
<td>Long by value. The distance in PowerBuilder units of the scroll box from the left end of the scroll bar (if the DataWindow is split, in the pane being scrolled).</td>
</tr>
</tbody>
</table>
| pane | Integer by value. The number of the pane being scrolled. (When the DataWindow is split with two scroll bars, there are two panes.) Values are:
  • 1 – The left pane (if the scroll bar is not split, the only pane).
  • 2 – The right pane. |

Web ActiveX event information
Event name: onScrollHorizontal

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position</td>
<td>Number. The distance in PowerBuilder units of the scroll box from the left end of the scroll bar (if the DataWindow is split, in the pane being scrolled).</td>
</tr>
</tbody>
</table>
| Pane | Number. The number of the pane being scrolled (when the DataWindow is split with two scroll bars, there are two panes). Values are:
  • 1 – The left pane (if the scroll bar is not split, the only pane).
  • 2 – The right pane. |
ScrollVertical

Return codes
There are no special outcomes for this event. The only code is:

0 Continue processing

Examples
This example displays the customer ID of the current row (the cust_id column) in a SingleLineEdit control when the pane being scrolled is pane 1 and the position is greater than 100:

```powerbuilder
string ls_id
ls_id = ""
IF pane = 1 THEN
    IF scrollpos > 100 THEN
        ls_id = String(dw_1.Object.Id[dw_1.GetRow()])
    END If
END IF
sle_message.Text = ls_id
RETURN 0
```

ScrollVertical

ScrollVertical

Description
Occurs when user scrolls up or down in the DataWindow with the Tab or arrow keys or the scroll bar.

PowerBuilder event information
Event ID: pbm_dwnvscroll

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scrollpos</td>
<td>Long by value. The distance in PowerBuilder units of the scroll box from the top of the scroll bar.</td>
</tr>
</tbody>
</table>

Web ActiveX event information
Event name: onScrollVertical

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position</td>
<td>Number. The distance in PowerBuilder units of the scroll box from the top of the scroll bar.</td>
</tr>
</tbody>
</table>

Return codes
There are no special outcomes for this event. The only code is:

0 Continue processing

Examples
As the user scrolls vertically, this script displays the range of rows currently being displayed in the DataWindow:

```powerbuilder
long ll_numrows
```
string ls_firstrow, ls_lastrow

ll_numrows = dw_1.RowCount()
ls_firstrow = dw_1.Object.Datawindow.FirstRowOnPage
ls_lastrow = dw_1.Object.Datawindow.LastRowOnPage

sle_message.Text = "Rows " + ls_firstrow &
+ " through " + ls_lastrow + " of " &
+ String(ll_numrows)

RETURN 0

See also ScrollHorizontal

### SQLPreview

**Description**

Occurs immediately before a SQL statement is submitted to the DBMS. Methods that trigger DBMS activity are Retrieve, Update, and ReselectRow.

#### PowerBuilder event information

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| request    | SQLPreviewFunction by value. The function that initiated the database activity.  
For a list of valid values, see SQLPreviewFunction on page 488. |
| sqltype    | SQLPreviewType by value. The type of SQL statement being sent to the DBMS.  
For a list of valid values, see SQLPreviewType on page 489. |
| sqlsyntax  | String by value. The full text of the SQL statement. |
| buffer     | DWBuffer by value. The buffer containing the row involved in the database activity.  
For a list of valid values, see DWBuffer on page 478. |
| row        | Long by value. The number of the row involved in the database activity, that is, the row being updated, selected, inserted, or deleted. |

#### Web ActiveX event information

Event name: beforeSQLPreview
SQLPreview

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request</td>
<td>Number. A number identifying the function that initiated the database activity. For a list of valid values, see SQLPreviewFunction on page 488.</td>
</tr>
<tr>
<td>SQLType</td>
<td>Number. A number identifying the type of SQL statement being sent to the DBMS. For a list of valid values, see SQLPreviewType on page 489.</td>
</tr>
<tr>
<td>SQLSyntax</td>
<td>String. The full text of the SQL statement.</td>
</tr>
<tr>
<td>dwBuffer</td>
<td>Number. A number identifying the buffer containing the row involved in the database activity. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>Row</td>
<td>Number. The number of the row involved in the database activity—that is, the row being updated, selected, inserted, or deleted.</td>
</tr>
</tbody>
</table>

**Return codes**

Set the return code to affect the outcome of the event:

- 0  Continue processing
- 1  Stop processing
- 2  Skip this request and execute the next request

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

**Usage**

Some uses for the SQLSyntax argument are:

- Changing the SQL to be executed (you can get the value of SQLSyntax, modify it, and call SetSQLPreview)
- Keeping a record (you can write the SQL statement to a log file)

**Reported row number**

The row number stored in row is the number of the row in the buffer, not the number the row had when it was retrieved into the DataWindow object.

If the row that caused the error is in the Filter buffer, you must unfilter it if you want the user to correct the problem.

**GetSQLPreview and binding**

When binding is enabled for your database, the SQL returned in the GetSQLPreview method may not be complete—the input arguments are not replaced with the actual values. For example, when binding is enabled, GetSQLPreview might return the following SQL statement:
INSERT INTO "cust_order" ("ordnum", "custnum", "duedate", "balance") VALUES (?, ?, ?, ?)

When binding is disabled, it returns:

INSERT INTO "cust_order" ("ordnum", "balance", "duedate", "custnum") VALUES (12345, 900, '3/1/94', '111')

If you require the complete SQL statement for logging purposes, you should disable binding in your DBMS.

For more information about binding, see Connecting to Your Database.

Obsolete methods in PowerBuilder Information formerly provided by GetSQLPreview and GetUpdateStatus is available in the arguments sqlsyntax, row, and buffer.

Examples

This statement in the SQLPreview event sets the current SQL string for the DataWindow dw_1:

dw_1.SetSQLPreview( &
"INSERT INTO billings VALUES(100, " + &
String(Current_balance) + ";")"
)

TabDownOut

Description Occurs when the user presses Enter or the down arrow to change focus to the next control in a window or user object.

PowerBuilder event information

Event ID: pbm_dwntabdownout

TabDownOut is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwntabdownout.

Web ActiveX event information

Event Name: onTabDownOut

Return codes There are no special outcomes for this event. The only code is:

0 Continue processing
**TabOut**

**Description**

Occurs when the user presses Tab or, in some edit styles, the right arrow, to move to the next control in a window or user object.

**PowerBuilder event information**

Event ID: pbm_dwntabout

TabOut is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwntabout.

**Web ActiveX event information**

Event Name: onTabOut

**Return codes**

There are no special outcomes for this event. The only code is:

0  Continue processing

---

**TabUpOut**

**Description**

Occurs when the user presses Shift+Enter or the up arrow to move to the previous control in a window or user object.

**PowerBuilder event information**

Event ID: pbm_dwntabupout

TabUpOut is not a standard PowerBuilder DataWindow event. To write a script for this event, you must first define a user-defined event for the event ID pbm_dwntabupout.

**Web ActiveX event information**

Event Name: onTabUpOut

**Return codes**

There are no special outcomes for this event. The only code is:

0  Continue processing

---

**TreeNodeSelected**

**Description**

Occurs after a node in a TreeView DataWindow is selected.

**PowerBuilder event information**

Event ID: pbm_dwntreenodeselected
DataWindow Reference

CHAPTER 8    DataWindow Events

Return codes
There are no return codes.

Usage
A TreeView node is selected when the user clicks the State icon (-) in the TreeView DataWindow or uses any of the Collapse methods.

The TreeNodeSelected event occurs after the selecting operation when the user selects a tree node using the SelectTreeNode method.

Examples
The following statements in the TreeNodeSelected event refresh the text box value with the new node:

```
sle_row.text = string(row)
sle_level.text = string(grouplevel)
return 0
```

See also
TreeNodeSelecting

---

**TreeNodeSelecting**

Description
Occurs before a node in a TreeView DataWindow is selected.

**PowerBuilder event information**
Event ID: pbm_dwntreenodeselecting

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Long by value. The number of the first row in the group to be selected.</td>
</tr>
<tr>
<td>grouplevel</td>
<td>Long by value. The TreeView level of the group to be selected.</td>
</tr>
</tbody>
</table>

Return codes
Set the return code to affect the outcome of the event. Return 0 to continue the selecting operation or return any other value to cancel the selecting operation.

Usage
The TreeNodeSelecting event occurs before the user selects a TreeNode or uses the SelectTreeNode method.
UpdateEnd

Examples

The following statements in the TreeNodeSelecting event refresh the text box value with the new node:

```powershell
sle_row.text = string(row)
sle_level.text = string(grouplevel)
return 0
```

See also

TreeNodeSelected

UpdateEnd

Description

Occurs when all the updates to the database from the DataWindow (or DataStore) are complete.

PowerBuilder event information

Event ID: pbm_dwnupdateend

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowsinserted</td>
<td>Long by value. The number of rows inserted.</td>
</tr>
<tr>
<td>rowsupdated</td>
<td>Long by value. The number of rows updated.</td>
</tr>
<tr>
<td>rowsdeleted</td>
<td>Long by value. The number of rows deleted.</td>
</tr>
</tbody>
</table>

Web ActiveX event information

Event name: afterUpdate

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RowsInserted</td>
<td>Number. The number of rows inserted.</td>
</tr>
<tr>
<td>RowsUpdated</td>
<td>Number. The number of rows updated.</td>
</tr>
<tr>
<td>RowsDeleted</td>
<td>Number. The number of rows deleted.</td>
</tr>
</tbody>
</table>

Return codes

There are no special outcomes for this event. The only code is:

0  Continue processing

See also

RetrieveStart
SQLPreview
UpdateStart
CHAPTER 8  DataWindow Events

UpdateStart

Description
Occurs after a script calls the Update method and just before changes in the DataWindow or DataStore are sent to the database.

PowerBuilder event information
Event ID: pbm_dwnupdatestart

Web DataWindow client control event information
Event name: UpdateStart

Web ActiveX event information
Event name: beforeUpdate

Return codes
Set the return code to affect the outcome of the event:

0  Continue processing
1  Do not perform the update

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

See also
RetrieveStart
SQLPreview
UpdateEnd

WSError

Description
Occurs when an error is returned for a DataWindow using a Web service data source. The error can occur during any of the following operations: connect, retrieve, delete, insert, update, or disconnect.

PowerBuilder event information
Event ID: pbm_dwnwsserror

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>String for the type of operation (Retrieve, Update, Insert, Delete, Connect, or Disconnect)</td>
</tr>
<tr>
<td>rownum</td>
<td>Long for the row number or 0 if not applicable, such as when an error occurs during connection to the Web service</td>
</tr>
<tr>
<td>buffernname</td>
<td>String for the name of the buffer being accessed while the error occurred (Primary, Filter, or Delete)</td>
</tr>
<tr>
<td>wssinfo</td>
<td>String for the WSDL file, the URL that defines the Web service, or the assembly that is used access the Web service</td>
</tr>
</tbody>
</table>
WSError

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>method</td>
<td>String for the name of the Web service method invoked</td>
</tr>
<tr>
<td>errormessage</td>
<td>String for the exception message returned from the method</td>
</tr>
</tbody>
</table>

Return codes

Set the return code to affect the outcome of the event:

- 0  Display the error message
- 1  Do not display the error message

For information on setting the return code in a particular environment, see “About return values for DataWindow events” on page 499.

Usage

Because you cannot use the DBError event with a Web Service DataWindow, you must use the WSError event to obtain any error information.

Examples

The following code in a WSError event script causes information about an error to display in a message box:

```
MessageBox("Error event", "Error in row " &
           + string(rownum) + ", Occurred during " + method &
           + "; the cause of the error is: " + errormessage)
```

DBError
CHAPTER 9

Methods for the DataWindow Control

About this chapter
This chapter documents the methods of the DataWindow control in the PowerBuilder and Web environments. You will find syntax, notes, and examples for all environments.

Methods for graphs are in Chapter 10, “Methods for Graphs in the DataWindow Control.”

Contents
The methods in this chapter are listed alphabetically.

Before you begin
For methods (or functions) in the PowerBuilder environment that apply to controls other than DataWindows and DataStores, see the PowerScript Reference.
AboutBox

Description
Displays a dialog identifying the DataWindow, including copyright and version information.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

Web ActiveX

void dwcontrol.AboutBox ( )

Return value
None

AcceptText

Description
Applies the contents of the DataWindow’s edit control to the current item in the buffer of a DataWindow control or DataStore. The data in the edit control must pass the validation rule for the column before it can be stored in the item.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

integer dwcontrol.AcceptText ( )

Web DataWindow client control and Web ActiveX

number dwcontrol.AcceptText ( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

Return value
Returns 1 if it succeeds and –1 if it fails (for example, the data did not pass validation).

If there is no DataWindow object assigned to the DataWindow control or DataStore, this method returns 1.
Usage

When a user moves from item to item in a DataWindow control, the control validates and accepts data the user has edited.

**How to call AcceptText** When a user modifies a DataWindow item then immediately changes focus to another control in the window, the DataWindow control does not accept the modified data—the data remains in the edit control. Use the AcceptText method in this situation to ensure that the DataWindow object contains the data the user edited.

However, you must not call AcceptText in the LoseFocus event or in a user event posted from LoseFocus if the DataWindow control still has focus. If you do, an infinite loop can occur.

*The problem* Normally, new data is validated and accepted when the user moves to a new cell in the DataWindow. If the new data causes an error, a message box displays, which causes the DataWindow to lose focus. If you have also coded the LoseFocus event or an event posted from LoseFocus to call AcceptText to validate data when the control loses focus, this AcceptText runs because of the message box and triggers an infinite loop of validation errors.

*The solution* It is desirable to validate the last changed data when the control loses focus. You can accomplish this by making sure AcceptText gets called only when the DataWindow control really has lost focus. The third PowerBuilder example illustrates how to use an instance variable to keep track of whether the DataWindow control has focus. The posted event calls AcceptText only when the DataWindow control does not have focus.

This is a change from previous versions of PowerBuilder. Previously, the posted user event would run while the message box for the validation error was displayed. Now, it runs after the message box is dismissed, causing another validation error to occur and another message box to be displayed, resulting in an infinite loop.

**Events** AcceptText can trigger an ItemChanged or an ItemError event.

**AcceptText in the ItemChanged event**

Calling AcceptText in the ItemChanged event has no effect.
Examples

In this example, the user is expected to enter a key value (such as an employee number) in a column of the DataWindow object, then click the OK button. This script for the Clicked event for the button calls AcceptText to validate the entry and place it in the DataWindow control. Then the script uses the item in the Retrieve method to retrieve the row for that key:

```plaintext
IF dw_emp.AcceptText() = 1 THEN
    dw_emp.Retrieve(dw_emp.GetItemNumber &
        (dw_emp.GetRow(), dw_emp.GetColumn()))
END IF
```

This script for the Clicked event for a CommandButton accepts the text in the DataWindow dw_Emp and counts the rows in which the column named balance is greater than 0:

```plaintext
integer i, Count
dw_employee.AcceptText()
FOR i = 1 to dw_employee.RowCount()
    IF dw_employee.GetItemNumber(i,'balance') &
        > 0 THEN
        Count = Count + 1
    END IF
NEXT
```

This example illustrates how to validate newly entered data when the DataWindow control loses focus. An instance variable keeps track of whether the DataWindow control has focus. It is set in the GetFocus and LoseFocus events. The LoseFocus event posts the ue_acceptText event, which calls the AcceptText method only if the DataWindow control does not have focus.

The instance variable:

```plaintext
boolean dw_has_focus
```

The GetFocus event:

```plaintext
dw_has_focus = true
```

The LoseFocus event:

```plaintext
dw_has_focus = false
dw_1.event post ue_acceptText()
```

The ue_acceptText event:

```plaintext
IF dw_has_focus = false THEN
    dw_1.accepttext()
END IF
```

See also Update
CanUndo

Description
Tests whether Undo can reverse the most recent edit in the editable control over the current row and column.

Applies to
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

boolean dwcontrol.CanUndo()

Web ActiveX

boolean dwcontrol.CanUndo()

Argument | Description
---------|------------------
dwcontrol | A reference to a DataWindow control

Return value
Returns true if the last edit can be reversed (undone) using the Undo method and false if the last edit cannot be reversed.

If dwcontrol is null, the method returns null.

Usage

PowerBuilder environment
For use with other PowerBuilder controls, see CanUndo in the PowerScript Reference.

Examples
These statements check to see if the last edit in the edit control of dw_contact can be reversed; if yes the statements reverse it, and if no they display a message:

IF dw_contact.CanUndo() THEN
    dw_contact.Undo()
ELSE
    MessageBox(Parent.Title, "Nothing to Undo")
END IF

See also
Undo
### ClassName

**Description**
Provides the class (or name) of the specified object.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```plaintext
string dwcontrol.ClassName ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

**Return value**

Returns the class of `dwcontrol`, the name assigned to the control. Returns the empty string ("") if an error occurs.

**Usage**

Method inherited from PowerObject. For use with variables in the PowerBuilder environment, see `ClassName` in *PowerScript Reference*.

### Clear

**Description**
Deletes selected text in the edit control over the current row and column, but does not store it in the clipboard.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```plaintext
long dwcontrol.Clear ()
```

**Web ActiveX**

```plaintext
number dwcontrol.Clear ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of characters that `Clear` removed from `dwcontrol`. If no text is selected, no characters are removed and `Clear` returns 0. If an error occurs, `Clear` returns –1.
Usage

To select text for deleting, the user can use the mouse or keyboard. You can also call the SelectText method in a script.

To delete selected text and store it in the clipboard, use the Cut method.

**PowerBuilder environment**

For use with other PowerBuilder controls, see Clear in the *PowerScript Reference*.

Examples

If the user is editing the emp_name column in dw_emp and selects the text Wilson, this statement clears Wilson from the edit control and returns 6:

```plaintext
long chars_returned
chars_returned = dw_emp.Clear()
```

If the text in the edit control in dw_emp is Wilson, the first statement selects the W and the second clears W from the edit control. The return value would be 1:

```plaintext
dw_emp.SelectText(1,1)
dw_emp.Clear()
```

Cut  
Paste  
ReplaceText  
SelectText

---

**ClearValues**

**Description**

Deletes all the items from a value list or code table associated with a DataWindow column. (A value list is called a code table when it has both display and data values.) ClearValues does not affect the data stored in the column.

**ClearValuesByColNum**

A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

---

DataWindow Reference  571
ClearValues

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
integer dwcontrol.ClearValues ( string column )
integer dwcontrol.ClearValues ( integer column )
```

**Web DataWindow server component**

```powershell
short dwcontrol.ClearValues ( string column )
short dwcontrol.ClearValuesByColNum ( short column )
```

**Web ActiveX**

```powershell
number dwcontrol.ClearValues ( string column )
number dwcontrol.ClearValues ( number column )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td>column</td>
<td>The column whose value list you want to delete. Column can be a column number (integer) or a column name (string). For the Web DataWindow server component, when the column is a number, use the ClearValuesByColNum method.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. The return value is usually not used.

Usage

The edit style of the column can be DropDownListBox, Edit, or RadioButton. ClearValues has no effect when column has the EditMask or DropDownListDataWindow edit style.

Examples

This statement clears all values from the drop-down list of dw_Employee’s status column:

```powershell
dw_Employee.ClearValues("status")
```

See also

GetValue
SetValue
**Collapse**

**Description**
Collapses a group in a TreeView DataWindow that has the specified TreeView level and includes the specified row.

**Applies to**
- **DataWindow type**: PowerBuilder
- **Method applies to**: DataWindow control

**Syntax**
**PowerBuilder**

```
Integer dw_control.Collapse(long row, long groupLevel)
```

**Argument** | **Description**
--- | ---
`dw_control` | A reference to a TreeView-style DataWindow control
`row` | The number of the row that belongs to the TreeView level of the group to be collapsed
`groupLevel` | The TreeView level of the group to be collapsed

**Return value**
Returns 1 if the collapse operation succeeds and one of the following negative values if it fails:
- `-1` DataWindow is null
- `-5` One or more of the parameters are invalid
- `-16` DataWindow is not a TreeView DataWindow

**Usage**
A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the `Collapse` method to collapse a group in a TreeView DataWindow that includes a particular row in a particular TreeView level.

The `Collapse` method triggers the Collapsing and Collapsed events.

**Examples**
The following example collapses the group at TreeView level 2 that includes row 3:

```powershell
integer li_ret
li_ret = dw_treeview.Collapse(3,2)
```

**See also**
- CollapseAll
- CollapseAllChildren
- CollapseLevel
- Expand
**CollapseAll**

**Description**
Collapses all groups in a TreeView DataWindow.

**Applies to**
- **DataWindow type**: PowerBuilder
- **Method applies to**: DataWindow control

**Syntax**

```powerbuilder
define procedure CollapseAll ( )
  dw_control.
enddefine
```

**Argument** | **Description**
--- | ---
`dw_control` | A reference to a TreeView-style DataWindow control

**Return value**
Returns 1 if the CollapseAll operation succeeds and one of the following negative values if it fails:

- `-1` DataWindow is null
- `-16` DataWindow is not a TreeView DataWindow

**Usage**
A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the CollapseAll method to collapse all groups in a TreeView DataWindow.

The CollapseAll method triggers the Collapsing and Collapsed events with row and level arguments of –1.

**Examples**
The following example collapses all groups:

```powerbuilder
integer li_ret
li_ret = dw_treeview.CollapseAll()
```

**See also**
- Collapse
- CollapseAllChildren
- CollapseLevel
- ExpandAll
CollapseAllChildren

Description
Collapses a group in a TreeView DataWindow that has the specified TreeView level and includes the specified row; also collapses all the group’s children.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
Integer dw_control.ExpandAllChildren(long row, long groupLevel)
```

**Argument** | **Description**
---|---
`dw_control` | A reference to a TreeView-style DataWindow control
`row` | The number of the row that belongs to the group to be collapsed
`groupLevel` | The TreeView level of the group to be collapsed

Return value

Returns 1 if the expand operation succeeds and one of the following negative values if it fails:

- `-1` DataWindow is null
- `-5` One or more of the parameters are invalid
- `-16` DataWindow is not a TreeView DataWindow

Usage

A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the `CollapseAllChildren` method to collapse a group with a specified TreeView level in a TreeView DataWindow and all of its children.

The `CollapseAllChildren` method triggers the Collapsing and Collapsed events.

Examples

The following example collapses the group in a TreeView DataWindow that has TreeView level 2 and includes row 3 and all the group’s children:

```powershell
integer li_ret
li_ret = dw_treeview.CollapseAllChildren(3,2)
```

See also

Collapse
CollapseAll
CollapseLevel
ExpandAllChildren
**CollapseLevel**

**Description**
Collapses all the groups in a TreeView DataWindow that have the specified TreeView level.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
Integer dw_control.CollapseLevel (long groupLevel)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dw_control</td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
<tr>
<td>groupLevel</td>
<td>The TreeView level of the group to be collapsed</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if the CollapseLevel operation succeeds and one of the following negative values if it fails:

- **-1** DataWindow is null
- **-5** One or more of the parameters are invalid
- **-16** DataWindow is not a TreeView DataWindow

**Usage**

A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the `CollapseLevel` method to collapse all the groups in a TreeView DataWindow that have a particular TreeView level.

The `CollapseLevel` method triggers the Collapsing and Collapsed events with a row argument of –1.

**Examples**

The following example collapses TreeView level 2:

```
integer li_ret
li_ret = dw_treeview.CollapseLevel(2)
```

CHAPTER 9  Methods for the DataWindow Control

Copy

Description Puts selected text from the current row and column of an edit control onto the clipboard. Copy does not change the source text.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, OLE DWObject</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
integer objectref.Copy()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| objectref | A reference to a DataWindow control  
or  
The fully qualified name of a OLE DWObject within a DataWindow control that contains the object you want to copy to the clipboard. The fully qualified name for a DWObject has this syntax: `dwcontrol.Object.dwobjectname` |

Return value Returns the number of characters that were copied to the clipboard. If no text is selected in `objectref`, no characters are copied and `Copy` returns 0. If an error occurs, `Copy` returns −1.

For OLE DWO objects, `Copy` returns 0 if it succeeds and one of the following negative values if an error occurs:

-1  Container is empty  
-2  Copy Failed  
-9  Other error

If `objectref` is null, the method returns null.

Usage To select text for copying, the user can use the mouse or keyboard. You can also call the SelectText method in a script. For the RichTextEdit presentation style in PowerBuilder, there are several additional methods for selecting text: SelectTextAll, SelectTextLine, and SelectTextWord.

To insert the contents of the clipboard into a control, use the `Paste` method.

`Copy` does not delete the selected text or OLE object. To delete the data, use the `Clear` or `Cut` method.
PowerBuilder environment
For use with other PowerBuilder controls, see Copy in the PowerScript Reference.

Examples
Assuming the selected text in the edit control of dw_emp is Temporary Address, these statements copy Temporary Address to the clipboard and store 17 in copy_amt:

```powerbuilder
integer copy_amt
copy_amt = dw_emp.Copy()
```

See also

Clipboard in the PowerScript Reference
Cut
Paste
ReplaceText
SelectText

CopyRTF

Description
Returns the selected text, pictures, and input fields in a RichText DataWindow as a string with rich text formatting. Bitmaps and input fields are included in the string.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
string dwcontrol.CopyRTF ( { boolean selected, Band band } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore object. The DataWindow object in the DataWindow control or DataStore must be a RichText DataWindow.</td>
</tr>
<tr>
<td>selected</td>
<td>(optional) A value indicating whether to copy selected text only. Values are:</td>
</tr>
<tr>
<td></td>
<td>• true – (Default) Copy selected text only.</td>
</tr>
<tr>
<td></td>
<td>• false – Copy the entire contents of the band.</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Return value

Returns the selected text as a string.

CopyRTF returns an empty string (""") if:
• There is no selection and selected is true
• An error occurs

Usage

CopyRTF does not involve the clipboard. The copied information is stored in a string. If you use the standard clipboard methods (Copy and Cut) the clipboard will contain the text without any formatting.

To incorporate the text with RTF formatting into another RichTextEdit control, use PasteRTF.

PowerBuilder environment

For use with RichTextEdit controls, see CopyRTF in the PowerScript Reference. For information about rich text format, see the chapter about implementing rich text in Application Techniques.

Examples

This statement returns the text that is selected in the RichText DataWindow dw_letter and stores it in the string ls_richtext:

```powerbuilder
string ls_richtext
ls_richtext = dw_letter.CopyRTF()
```

This example copies the text in dw_1, saving it in ls_richtext, and pastes it into dw_2. The user clicks the RadioButton rb_true to copy selected text and rb_false to copy all the text. The number of characters pasted is saved in ll_numchars reported in the StaticText st_status:

```powerbuilder
string ls_richtext
boolean lb_selected
long ll_numchars

IF rb_true.Checked = true THEN
  lb_selected = true
ELSE
  lb_selected = false
END IF
```
Create

Description

Creates a DataWindow object using DataWindow source code and puts that object in the specified DataWindow control or DataStore object. This dynamic DataWindow object does not become a permanent part of the application source library.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerscript
integer dwcontrol.Create ( string syntax {, string errorbuffer } )
```

**Web DataWindow**

```powerscript
string dwcontrol.Create ( string syntax )
```

**Web ActiveX**

```powerscript
number dwcontrol.Create ( string syntax )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control or DataStore in which PowerBuilder will create the new DataWindow object.</td>
</tr>
<tr>
<td>syntax</td>
<td>A string whose value is the DataWindow source code that will be used to create the DataWindow object.</td>
</tr>
<tr>
<td>errorbuffer</td>
<td>The name of a string that will hold any error messages that are generated. If you do not specify an error buffer, a message box will display the error messages.</td>
</tr>
</tbody>
</table>
Return value

In PowerBuilder and the Web ActiveX, returns 1 if it succeeds and -1 if an error occurs. In the Web DataWindow, returns the string that holds error messages (see errorbuffer).

If any argument’s value is null, the method returns null.

Usage

The Create method creates a DataWindow object using the source code in syntax. It substitutes the new DataWindow object for the DataWindow object currently associated with dwcontrol.

DataWindow source code syntax is complex and is best produced by copying existing DataWindows. In a PowerBuilder application, you can use the Describe and LibraryExport methods to obtain the source code of existing DataWindows to use as models. In the PowerBuilder development environment, you can export the syntax of a DataWindow object in the Library painter.

Another source of DataWindow code is the SyntaxFromSQL method, which creates DataWindow source code based on a SQL statement. Many values in the source code syntax correspond to properties of the DataWindow object, which are documented in Chapter 3, “DataWindow Object Properties.”

When you examine syntax for existing DataWindow objects, you will see that the order of the syntax can vary. Release must be the first statement, and DataWindow should be the next statement. If you change the order, use care; the order can affect the results.

**Calling SyntaxFromSQL as the syntax argument**

You can call SyntaxFromSQL directly as the value for syntax. However, this does not give you the chance to check whether errors have been reported in its error argument. Before you use SyntaxFromSQL in Create, make sure the SQL syntax is valid.

**Comments**

To designate text in your DataWindow syntax as a comment, use either of the standard PowerBuilder methods:

- Use double slashes (//) to indicate that the text after the slashes and on the same line is a comment.
  
  When you use this method, the comment can be all or part of a line but cannot cover multiple lines; the compiler ignores everything following the double slashes on the line.

- Begin a comment with slash asterisk (/*) and end it with asterisk slash (*/) to indicate that all the text between the delimiters is a comment.
When you use this method, the comment can be all or part of a line or occupy multiple lines; the compiler ignores everything between /* and */.

**For DataWindows in group boxes** If a DataWindow object is in a group box, it is not automatically moved to the top when you call Create, even if the BringToTop property is set to true in the DataWindow painter. You must explicitly set the BringToTop property to true after you call Create. For example:

```powerbuilder
dw_1.Create(ls_syntax, ls_errors)
dw_1.BringToTop=true
```

**Examples**

These statements create a new DataWindow in the control dw_new from the DataWindow source code returned by the SyntaxFromSQL method. Errors from SyntaxFromSQL and Create are displayed in the MultiLineEdits mle_sfs and mle_create. After creating the DataWindow, you must call SetTransObject for the new DataWindow object before you can retrieve data:

```powerbuilder
string error_syntaxfromSQL, error_create
string new_sql, new_syntax

new_sql = 'SELECT emp_data.emp_id, ' &
  + 'emp_data.emp_name ' &
  + 'from emp_data ' &
  + 'WHERE emp_data.emp_salary>45000'

new_syntax = SQLCA.SyntaxFromSQL(new_sql, &
  'Style(Type=Form)', error_syntaxfromSQL)

IF Len(error_syntaxfromSQL) > 0 THEN
  // Display errors
  mle_sfs.Text = error_syntaxfromSQL
ELSE
  // Generate new DataWindow
  dw_new.Create(new_syntax, error_create)
  IF Len(error_create) > 0 THEN
    mle_create.Text = error_create
  END IF
END IF

dw_new.SetTransObject(SQLCA)
dw_new.Retrieve()
```

**See also**

SyntaxFromSQL in *PowerScript Reference*
SetTrans
SetTransObject
**CreateError**

**Description**
Returns the error messages that were generated during a previous call to Create.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

```web_activeX
string dwcontrol.CreateError() 
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control for which you just called the Create method</td>
</tr>
</tbody>
</table>

**Return value**
Returns a string whose value is the error message text that was generated when attempting to create a DataWindow from source code. If no errors occur, returns an empty string.

**Usage**
Call `CreateError` immediately after the `Create` method to get error messages generated by Create.

**See also**
Create

---

**CreateFrom**

**Description**
Creates a DataStore object from the passed ResultSet object.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataStore object</td>
</tr>
</tbody>
</table>

**Syntax**

```powerbuilder
integer dsobject.CreateFrom(ResultSet rssource)
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dsobject</td>
<td>The name of the DataStore object into which you want to place the data in the passed result set</td>
</tr>
<tr>
<td>rssource</td>
<td>A ResultSet or ADOResultSet object that contains meta data from which the DataStore object is created</td>
</tr>
</tbody>
</table>

**Return value**
Integer. Returns 1 if it succeeds or a negative number if an error occurs. If any argument is null, in PowerBuilder the method returns null.
CreateFrom

Usage

Use `CreateFrom` to create a DataStore from a passed result set. Typically, a PowerBuilder client calls methods on a component running in a transaction server and converts results sets returned from those methods to DataStore objects using `CreateFrom`.

`CreateFrom` creates an external DataWindow definition with no visual component—it has no controls and the height of all bands is zero. Since the data source for the DataStore object is external, Update methods on the DataStore object have no effect. The Print method will print a blank page.

Client applications can use the DataStore object directly or display the data in a DataWindow control using the ShareData method.

For more information about result sets and methods for exchanging data between components and clients, see Usage for `GenerateResultSet`.

Examples

This example creates an instance of the SVUBookstore component, calls the `GetMajors` method, and creates a DataStore object using the data definition in the returned ResultSet object:

```powershell
SVUBookstore lcst_mybookstore
resultset lrs_resultset
datastore ds_local
integer li_rc

li_rc = myconnect.CreateInstance(lcst_mybookstore)
IF li_rc <> 0 THEN
    MessageBox("Create Instance", string(li_rc) )
    myconnect.DisConnectServer()
    RETURN
END IF

lrs_resultset = lcst_mybookstore.GetMajors()

d_s_local = CREATE DataStore
d_s_local.CreateFrom(lrs_resultset)
```

This example creates a DataStore object from an ADO Recordset returned from a method on an MTS component.

```powershell
OLEObject loo_mycomponent
OLEObject loo_ADOrecordset
ADOREsultset lrs_ADOresultset
datastore ds_local
integer li_rc

loo_mycomponent = CREATE OLEObject
li_rc = loo_mycomponent.ConnectToNewObject("PB.Test")
```
IF li_rc <> 0 THEN
    MessageBox("Connect Failed", string(li_rc) )
    RETURN
END IF

// Use an OLEObject to hold ADO Recordset
// returned from method on MTS component
loo_ADOrecordset = loo_mycomponent.GetTestResult()

// Create an ADOResultSet and get its data
// from OLEObject holding passed ADO Recordset
lrs_ADOresultset = CREATE ADOResultSet
lrs_ADOresultset.SetRecordSet(loo_ADOrecordset)

// Use CreateFrom to populate DataStore
// from ADOResultSet object
ds_local = CREATE DataStore
ds_local.CreateFrom(lrs_ADOresultset)

See also
GenerateResultSet
SetRecordSet in the PowerScript Reference
SetResultSet in the PowerScript Reference

CrosstabDialog

**Description**
Displays the Crosstab Definition dialog box so the user can modify the definition of a crosstab DataWindow at runtime. The dialog box is the one you use in the DataWindow painter to define the crosstab.

**Applies to**
- **DataWindow type** | **Method applies to**
  - PowerBuilder | DataWindow control
  - Web ActiveX | DataWindow control

**Syntax**
- **PowerBuilder**
  ```
  integer dwcontrol.CrossTabDialog ( )
  ```
- **Web ActiveX**
  ```
  number dwcontrol.CrossTabDialog ( )
  ```

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to a DataWindow control
**Cut**

Return value

Returns 1 if it succeeds and –1 if an error occurs.

If `dwcontrol` is null, the method returns null.

Usage

If the style of the DataWindow object in the DataWindow control is not crosstab, `CrosstabDialog` has no effect. You must connect to a database and set the DataWindow control’s transaction object before you call `CrossTabDialog`.

Examples

This statement in the script for the CommandButton `cb_define` displays the Crosstab Definition dialog so the user can modify the definition of the crosstab DataWindow object in `dw_1`:

```powershell
dw_1.CrosstabDialog()
```

---

**Cut**

Description

Deletes selected text in the current row and column of an edit control and stores it on the clipboard, replacing the clipboard contents with the deleted text.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
long dwcontrol.Cut ()
```

**Web ActiveX**

```powershell
number dwcontrol.Cut ()
```

Argument | Description
---------|-------------
`dwcontrol` | A reference to a DataWindow control. The text is cut from the edit control over the current row and column.

Return value

Returns the number of characters that were cut from `dwcontrol` and stored in the clipboard. If no text is selected, no characters are cut and `Cut` returns 0. If an error occurs, `Cut` returns –1.

If `dwcontrol` is null, the method returns null.

Usage

To select text for deleting, the user can use the mouse or keyboard. You can also call the `SelectText` method in a script. For the RichTextEdit presentation style in PowerBuilder, there are several additional methods for selecting text: `SelectTextAll`, `SelectTextLine`, and `SelectTextWord`.

---

586 PowerBuilder
To insert the contents of the clipboard into a control, use the Paste method.
To delete selected text but not store it in the clipboard, use the Clear method.

**PowerBuilder environment**
For use with other PowerBuilder controls, see Cut in the *PowerScript Reference*.

**Examples**
Assuming the selected text in the edit control of dw_emp is Temporary, this statement deletes Temporary from the edit control, stores it in the clipboard, and returns 9:

```plaintext
dw_emp.Cut()
```

**See also**
Copy
Clear
Clipboard in the *PowerScript Reference*
Paste

### DBCancel

**Description**
Cancels the retrieval in process in a DataWindow.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```plaintext
integer dwcontrol.DBCancel ( )
```

**Web ActiveX**

```plaintext
number dwcontrol.DBCancel ( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control, DataStore, or child DataWindows</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.
Usage

To cancel a database retrieval, you need two pieces of code:

- Code that calls DBCancel. To let the user cancel the retrieval, you could call `DBCancel` (or call a user function or member method that calls it) in code for a button or an item on a menu. This code would generally set an instance variable or data member to indicate that the user requested cancellation.

  In PowerBuilder, this code might be:
  ```powerbuilder
  ib_cancel = true
  dw_1.DBCancel()
  ```

- Code for the RetrieveRow event that sets an action/return code of 1 to stop the retrieval.

  In PowerBuilder, this code might be:
  ```powerbuilder
  IF ib_cancel = true THEN
    RETURN 1
  END IF
  ```

Coding something in the RetrieveRow event’s script (even just a comment) enables the operating system to process events while the DataWindow is being populated with rows from the database. If the RetrieveRow event’s script is empty, menus and command buttons can’t even be clicked until the retrieval is completely finished. This can be frustrating if the user inadvertently starts a retrieval that is going to take a long time.

If the Async DBParm parameter is set to 1 (for asynchronous operation), a user or a script can cancel a query either before the first row is returned or during the data retrieval process. If Async is set to 0 (for synchronous operation), the user cannot select the menu or CommandButton until the first row is retrieved. The asynchronous setting is useful when a query might take a long time to retrieve its first row.

For a list of the DBMSs that support the Async DBParm parameter, see the Connection Reference.

Examples

In this example, the menu bar for an MDI application has menu items for starting and canceling a retrieval. When the user cancels the retrieval, a user function calls `DBCancel` and sets a boolean instance variable to `Get/SetSeriesStyle` and `Get/SetDataStyle`. The RetrieveStart and RetrieveRow events check this variable and return the appropriate value.
In this hypothetical application, the user starts a retrieval by selecting Retrieve from a menu. The script for the Retrieve menu item calls a user function for the window:

```plaintext
w_async1.wf_retrieve()
```

The `wf_retrieve` function sets the Async DBParm for asynchronous processing and starts the retrieval. Because Async is set to 1, the user can select the Cancel menu item at any time, even before the first row is retrieved. (In your own application, you would include error handling to make sure Retrieve returned successfully.)

```plaintext
long rc
ib_cancel = false
SQLCA.DBParm = 'Async = 1'
rc = dw_1.Retrieve()
```

The user can stop the retrieval by selecting Cancel from the menu. The script for the Cancel menu item reads:

```plaintext
w_async1.wf_cancel()
```

The user function `wf_cancel` for the window `w_async1` calls `DBCANCEL` and sets a flag indicating that the retrieval is canceled. Other events for the `DataWindow` will check this flag and abort the retrieval too. The variable `ib_cancel` is an instance variable for the window:

```plaintext
ib_cancel = true
dw_1.DBCancel()
```

Scripts for the RetrieveStart and RetrieveRow events both check the `ib_cancel` instance variable and, if it is true, stop the retrieval by returning a value of 1. In order to cancel the retrieval, some code or comment in the script for the `RetrieveRow` event is required:

```plaintext
IF ib_cancel = true THEN
    RETURN 1
END IF
```

See also Retrieve
DBErrorCode

Description
Reports the database-specific error code that triggered the DBError event.

Obsolete method
DBErrorCode is obsolete and will be discontinued in the future. You should replace all use of DBErrorCode as soon as possible. The database error code is available as an argument in the DBError event.

Applies to
DataWindow type | Method applies to
--- | ---
PowerBuilder | DataWindow control, DataWindowChild object

Syntax
**PowerBuilder**

```java
long dwcontrol.DBErrorCode()()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow</td>
</tr>
</tbody>
</table>

Return value
Returns an error code when a database error occurs in `dwcontrol`. Error codes –1 through –4 are PowerBuilder codes. Other codes are database-specific. Returns 0 if there is no error.

If `dwcontrol` is null, the method returns null.

PowerBuilder error codes are:

- –1 Can’t connect to the database because of missing values in the transaction object.
- –2 Can’t connect to the database.
- –3 The key specified in an Update or Retrieve no longer matches an existing row. (This can happen when another user has changed the row after you retrieved it.)
- –4 Writing a blob to the database failed.

Usage
When a database error occurs while a DataWindow control is interacting with the database, PowerBuilder triggers the DBError event. Since DBErrorCode is meaningful only if a database error has occurred, you should call this method only in the DBError event.

Examples
This statement returns the error code for `dw_employee`:

```java
dw_employee.DBErrorCode()
```
Since this method is meaningful only in a DataWindow DBError event, you can use the pronoun This instead of the DataWindow’s name:

This.DBErrorCode()

These statements check the error code for dw_employee and if it is -4, perform some processing:

```powershell
long ll_Error_Nbr
ll_Error_Nbr = This.DBErrorCode()
IF ll_Error_Nbr = -4 THEN ...
```

When an error occurs in dw_Emp, the following statements in the DBError event’s script will display the error number and message. A return code of 1 suppresses the default error message:

```powershell
long ll_Error_Nbr
ll_Error_Nbr = This.DBErrorCode()
IF ll_Error_Nbr <> 0 THEN
    MessageBox("Database Error", "Number " &
    + string(ll_Error_Nbr) + " " &
    + This.DBErrorMessage(), StopSign!)
    // Stop PowerBuilder from displaying the error
    RETURN 1
END IF
```

See also DBErrorMessage

### DBErrorMessage

**Description**

Reports the database-specific error message that triggered the DBError event.

**Obsolete method**

DBErrorMessage is obsolete and will be discontinued in a future release. You should replace all use of DBErrorMessage as soon as possible. The database error message is available as an argument in the DBError event.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

DataWindow Reference 591
**DBErrorMessage**

Syntax

```powerbuilder
string dwcontrol.DBEErrorMessage()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns a string whose value is a database-specific error message generated by a database error in `dwcontrol`. Returns the empty string ("") if there is no error.

If `dwcontrol` is null, the method returns null.

Usage

When a database error occurs while a DataWindow control is interacting with the database, PowerBuilder triggers the DBError event. Since `DBErrorMessage` is meaningful only if a database error has occurred, you should call this method only in the DBError event.

Examples

This statement returns the error message generated by a database error in `dw_employee`:

```powerbuilder
dw_employee.DBEErrorMessage()
```

Since this method is meaningful only in a DataWindow, you can use the pronoun `This` instead of the DataWindow’s name:

```powerbuilder
This.DBE ErrorMessage()
```

If data processing fails in `dw_Emp` and these statements are coded in the script for the DBError event, a message box containing the error number and the message displays:

```powerbuilder
string err_msg

err_msg = This.DBE ErrorMessage()

IF err_msg <> "" THEN
    MessageBox("DBError", "Number" + & String(This.DBE ErrorCode())+ " " + & err_msg, StopSign!)
    // Stop PowerBuilder from displaying the error
RETURN 1
END IF
```

See also

`DBErrorCode`
**DeletedCount**

Reports the number of rows that have been marked for deletion in the database.

**Description**

Reports the number of rows that have been marked for deletion in the database.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder and Web DataWindow server component**

`long dwcontrol.DeletedCount ()`

**Web DataWindow client control and Web ActiveX**

`number dwcontrol.DeletedCount ()`

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of rows that have been deleted from `dwcontrol` but not updated in the associated database table.

Returns 0 if no rows have been deleted or if all the deleted rows have been updated in the database table. `DeletedCount` returns –1 if it fails.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

An updatable DataWindow control or DataStore has several buffers. The primary buffer stores the rows currently being displayed. The delete buffer stores rows that the application has marked for deletion by calling the `DeleteRow` method. These rows are saved until the database is updated. You can use `DeletedCount` to find out if there are any rows in the delete buffer.

If a DataWindow is not updatable, rows that are deleted are discarded—they are not stored in the delete buffer. Therefore, `DeletedCount` returns 0 for a nonupdatable DataWindow unless a method, such as `RowsCopy` or `RowsMove`, has been used to populate the delete buffer.
DeleteRow

Examples

Assuming two rows in dw_employee have been deleted but have not been updated in the associated database table, these statements set ll_Del to 2:

```powerbuilder
Long ll_Del
ll_Del = dw_employee.DeletedCount()
```

This example tests whether there are rows in the delete buffer, and if so, updates the database table associated with dw_employee:

```powerbuilder
Long ll_Del
ll_Del = dw_employee.DeletedCount()
IF ll_Del <> 0 THEN dw_employee.Update()
```

RowCount

DeleteRow

Description

Deletes a row from a DataWindow control, DataStore object, or child DataWindow.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.DeleteRow ( long row )
```

**Web DataWindow client control and Web ActiveX**

```powerbuilder
number dwcontrol.DeleteRow ( number row )
```

**Web DataWindow server component**

```powerbuilder
short dwcontrol.DeleteRow ( long row )
```
DeleteRow deletes the row from the DataWindow’s primary buffer.

If the DataWindow is not updatable, all storage associated with the row is cleared. If the DataWindow is updatable, DeleteRow moves the row to the DataWindow’s delete buffer; PowerBuilder uses the values in the delete buffer to build the SQL DELETE statement.

The row is not deleted from the database table until the application calls the Update method. After the Update method has updated the database and the update flags are reset, the storage associated with the row is cleared.

Apply GetChanges after deleting rows in a distributed application
If a DataWindow or data store is populated using SetChanges or SetFullState, and an Update is done that includes deleted rows, the deleted rows remain in the delete buffer until a subsequent GetChanges is applied to the DataWindow or data store.

Web DataWindow client control  Calling DeleteRow causes the new status of the data to be sent back to the server where data is retrieved again minus the deleted row. Then the page is reloaded. But you must still call the Update method to update the database and the data on the server.

If the DataWindow object has retrieval arguments, they must be specified in the HTMLGen.SelfLinkArgs property. For more information, see the HTMLGen.property, the Retrieve method, and the DataWindow Programmers Guide.

All methods that reload the page perform an AcceptText before sending data back to the server. If the method fails (returns −1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.
Describe

Examples
This statement deletes the current row from dw_employee:

```powershell
dw_employee.DeleteRow(0)
```

These statements delete row 5 from dw_employee and then update the database with the change:

```powershell
dw_employee.DeleteRow(5)
dw_employee.Update()
```

DeletedCount
InsertRow

Describe

Description
Reports the values of properties of a DataWindow object and controls within the DataWindow object. Each column and graphic control in the DataWindow has a set of properties (listed in Chapter 3, “DataWindow Object Properties”). You specify one or more properties as a string, and Describe returns the values of the properties.

Describe can also evaluate expressions involving values of a particular row and column. When you include Describe’s Evaluate function in the property list, the value of the evaluated expression is included in the reported information.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder, Web DataWindow, and Web ActiveX**

```powershell
string dwcontrol.Describe ( string propertylist )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td><code>propertylist</code></td>
<td>A string whose value is a blank-separated list of properties or Evaluate functions.</td>
</tr>
<tr>
<td></td>
<td>For a list of valid properties, see Chapter 3, “DataWindow Object Properties.”</td>
</tr>
</tbody>
</table>
Return value

Returns a string that includes a value for each property or Evaluate function. A newline character (~n or \n) separates the value of each item in propertylist.

If the property list contains an invalid item, Describe returns an exclamation point (!) for that item and ignores the rest of the property list. Describe returns a question mark (?) if there is no value for a property.

When the value of a property contains an exclamation point or a question mark, the value is returned in quotes so that you can distinguish between the returned value and an invalid item or a property with no value.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Use Describe to understand the structure of a DataWindow. For example, you can find out which bands the DataWindow uses and what the datatypes of the columns are. You can also use Describe to find out the current value of a property and use that value to make further modifications.

Describe is often used to obtain the DataWindow’s SELECT statement in order to modify it (for example, by adding a WHERE clause).

When you can obtain the DataWindow’s SQL statement

When you use the Select painter to graphically create a SELECT statement, PowerBuilder saves its own SELECT statement (called a PBSELECT statement), and not a SQL SELECT statement, with the DataWindow definition.

When you call Describe with the property Table.Select, it returns a SQL SELECT statement only if you are connected to the database. If you are not connected to the database, Describe returns a PBSELECT statement.

Property syntax

The syntax for a property in the property list is:

controlname.property

For the types of controls in a DataWindow and their properties with examples, see Chapter 3, “DataWindow Object Properties.”

Properties whose value is a list

When a property returns a list, the tab character separates the values in the list. For example, the Bands property reports all the bands in use in the DataWindow as a list.

If the first character in a property’s returned value list is a quotation mark, it means the whole list is quoted and any quotation marks within the list are single quotation marks.
For example, the following is a single property value.

"Student[tab] Andrew 'or '[newline]Andy'"

**Specifying special characters** There are different ways of specifying special characters in a string in each environment:

<table>
<thead>
<tr>
<th>Character</th>
<th>PowerBuilder</th>
<th>JavaScript</th>
</tr>
</thead>
<tbody>
<tr>
<td>tab</td>
<td>~t</td>
<td>\t</td>
</tr>
<tr>
<td>newline</td>
<td>~n</td>
<td>\n</td>
</tr>
<tr>
<td>single quote</td>
<td>~'</td>
<td>'</td>
</tr>
<tr>
<td>double quote</td>
<td>~&quot;</td>
<td>&quot;</td>
</tr>
</tbody>
</table>

**Quoted property values** Describe returns a property’s value enclosed in quotes when the text would otherwise be ambiguous. For example, if the property’s value includes a question mark, then the text is returned in quotes. A question mark without quotes means that the property has no value.

**Column name or number** When the control is a column, you can specify the column name or a pound sign (#) followed by the column number. For example, if salary is column 5, then "salary.coltype" is equivalent to "#5.coltype".

**Control names** The DataWindow painter automatically gives names to all controls. (In previous versions of PowerBuilder, the painter only named columns and column labels.)

**Evaluating an expression** Describe’s Evaluate function allows you to evaluate DataWindow painter expressions within a script using data in the DataWindow. Evaluate has the following syntax, which you specify for propertylist.

```
Evaluate ('expression', rownumber)
```

**Expression** is the expression you want to evaluate and **rownumber** is the number of the row for which you want to evaluate the expression. The expression usually includes DataWindow painter functions. For example, in the following statement, Describe reports either 255 or 0 depending on the value of the salary column in row 3:

```
ls_ret = dw_1.Describe ( &
  "Evaluate('If(salary > 100000, 255, 0)', 3)"
)
```
You can call DataWindow control functions in a script to get data from the DataWindow, but some painter functions (such as LookUpDisplay) cannot be called in a script. Using Evaluate is the only way to call them. (See the example “Evaluating the display value of a DropDownDataWindow” on page 600.)

Sample property values  To illustrate the types of values that Describe reports, consider a DataWindow called dw_emp with one group level. Its columns are named emp and empname, and its headers are named emp_h and empname_h. The following table shows several properties and the returned value. In the first example below, a sample command shows how you might specify these properties for Describe and what it reports.

<table>
<thead>
<tr>
<th>Property</th>
<th>Reported value</th>
</tr>
</thead>
<tbody>
<tr>
<td>datawindow.Bands</td>
<td>header</td>
</tr>
<tr>
<td>datawindow.Objects</td>
<td>emp</td>
</tr>
<tr>
<td>emp.Type</td>
<td>column</td>
</tr>
<tr>
<td>empname.Type</td>
<td>column</td>
</tr>
<tr>
<td>empname_h.Type</td>
<td>text</td>
</tr>
<tr>
<td>emp.Coltype</td>
<td>char(20)</td>
</tr>
<tr>
<td>state.Type</td>
<td>! (! indicates an invalid item—there is no column named state)</td>
</tr>
<tr>
<td>empname_h.Visible</td>
<td>?</td>
</tr>
</tbody>
</table>

Examples

PowerBuilder examples

This example calls Describe with some of the properties shown in the previous table. The reported values (formatted with tabs and newlines) follow. Note that because state is not a column in the DataWindow, state.type returns an exclamation point (!):

```powershell
string ls_request, ls_report

ls_request = "DataWindow.Bands DataWindow.Objects " &
    + "empname_h.Text " &
    + "empname_h.Type emp.Type emp.Coltype " &
    + "state.Type empname>Type empname_h.Visible"

ls_report = dw_1.Describe(ls_request)
```

Describe sets the value of ls_report to the following string:

```
header|tab|detail|tab|summary|tab|footer|tab|header.1|tab|trailer.1-N
datawindow.Objects emp|tab|empname|tab|empname_h-N
empname|tab|temp_h|tab|tempname_h-N
empname_h-N
empname|tab|empname|tab|empname_h-N
empname_h|tab|temp_h|tab|tempname_h-N
empname_h|tab|empname|tab|empname_h-N
empname_h|tab|temp_h|tab|tempname_h-N
text-N
```

! (indicates an invalid item—there is no column named state)
These statements check the datatype of the column named salary before using GetItemNumber to obtain the salary value:

```powerbuilder
string ls_data_type
integer li_rate

ls_data_type = dw_1.Describe("salary.ColType")
IF ls_data_type = "number" THEN
li_rate = dw_1.GetItemNumber(5, "salary")
ELSE
    . . . // Some processing
END IF
```

**Column name or number**  This statement finds out the column type of the current column, using the column name:

```powerbuilder
s = This.Describe(This.GetColumnName()+ ".ColType")
```

For comparison, this statement finds out the same thing, using the current column’s number:

```powerbuilder
s = This.Describe("#" + String(This.GetColumn()) & + ".ColType")
```

**Scrolling and the current row**  This example, as part of the DataWindow control’s ScrollVertical event, makes the first visible row the current row as the user scrolls through the DataWindow:

```powerbuilder
s = This.Describe("DataWindow.FirstRowOnPage")
IF IsNumber(s) THEN This.SetRow(Integer(s))
```

**Evaluating the display value of a DropDownDataWindow**  This example uses Describe’s Evaluate function to find the display value in a DropDownDataWindow column called state_code. You must execute the code after the ItemChanged event, so that the value the user selected has become the item value in the buffer. This code is the script of a custom user event called getdisplayvalue:

```powerbuilder
string rownumber, displayvalue

rownumber = String(dw_1.GetRow())
displayvalue = dw_1.Describe( & + "Evaluate('LookUpDisplay(state_code) ', " & + rownumber + ")")
```

This code, as part of the ItemChanged event’s script, posts the getdisplayvalue event:

```powerbuilder
dw_1.PostEvent("getdisplayvalue")
```
Assigning null values based on the column’s datatype  The following excerpt from the ItemError event script of a DataWindow control allows the user to blank out a column and move to the next column. For columns with datatypes other than string, the user cannot leave the value empty (which is an empty string and does not match the datatype) without the return code. Data and row are arguments of the ItemError event:

```pascal
string s
s = This.Describe(This.GetColumnName() & + ".Coltype")

CHOOSE CASE s
CASE "number"
  IF Trim(data) = "" THEN
    integer null_num
    SetNull(null_num)
    This.SetItem(row, & This.GetColumn(), null_num)
    RETURN 3
  END IF
CASE "date"
  IF Trim(data) = "" THEN
    date null_date
    SetNull(null_date)
    This.SetItem(row, & This.GetColumn(), null_date)
    RETURN 3
  END IF
  . . . // Additional cases for other datatypes
END CHOOSE
```

See also  Create  Modify
Drag

Description
Starts or ends the dragging of a control.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
integer dwcontrol.Drag ( DragMode dragvalue )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow.</td>
</tr>
<tr>
<td>dragvalue</td>
<td>A value indicating the action you want to take on a control:</td>
</tr>
<tr>
<td></td>
<td>• Begin! – Put <code>dwcontrol</code> in drag mode.</td>
</tr>
<tr>
<td></td>
<td>• Cancel! – Stop dragging <code>dwcontrol</code> but do not cause a DragDrop event.</td>
</tr>
<tr>
<td></td>
<td>• End! – Stop dragging <code>dwcontrol</code> and if <code>dwcontrol</code> is over a target</td>
</tr>
<tr>
<td></td>
<td>object, cause a DragDrop event.</td>
</tr>
</tbody>
</table>

Usage
Inherited from DragObject. For information, see Drag in the *PowerScript Reference*.

Expand

Description
Expands a group in a TreeView DataWindow that has the specified TreeView level and includes the specified row.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
Integer dw_control.Expand(long row, long groupLevel)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dw_control</td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
<tr>
<td>row</td>
<td>The number of the row that belongs to the TreeView level of the group to be expanded</td>
</tr>
<tr>
<td>groupLevel</td>
<td>The TreeView level of the group to be expanded</td>
</tr>
</tbody>
</table>
Return value  
Returns 1 if the expand operation succeeds and one of the following negative values if it fails:

-1  DataWindow is null
-5  One or more of the parameters are invalid
-16  DataWindow is not a TreeView DataWindow

Usage  
A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the Expand method to expand a group in a TreeView DataWindow that includes a particular row in a particular TreeView level.

The Expand method triggers the Expanding and Expanded events.

Examples  
The following example expands the group at TreeView level 2 that includes row 3:

```powerbuilder
integer li_ret
li_ret = dw_treeview.Expand(3,2)
```

See also  
Collapse
ExpandAll
ExpandAllChildren
ExpandLevel
IsExpanded

**ExpandAll**

Description  
Expands all groups in a TreeView DataWindow.

Applies to  
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax  
**PowerBuilder**

```powerbuilder
Integer dw_control.ExpandAll( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dw_control</td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
</tbody>
</table>
ExpandAllChildren

Return value

Returns 1 if the ExpandAll operation succeeds and one of the following negative values if it fails:

-1  DataWindow is null

-16  DataWindow is not a TreeView DataWindow

Usage

A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the ExpandAll method to expand all groups in a TreeView DataWindow.

The ExpandAll method triggers the Expanding and Expanded events with row and level arguments of –1.

Examples

The following example expands all groups:

```powerbuilder
integer li_ret
li_ret = dw_treeview.ExpandAll()
```

See also

Collapse
Expand
ExpandAllChildren
ExpandLevel
IsExpanded

---

ExpandAllChildren

Description

Expands a group in a TreeView DataWindow that has the specified TreeView level and includes the specified row; also expands all the group’s children.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
Integer dw_control.ExpandAllChildren(long row, long groupLevel)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dw_control</td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
<tr>
<td>row</td>
<td>The number of the row that belongs to the group to be expanded</td>
</tr>
<tr>
<td>groupLevel</td>
<td>The TreeView level of the group to be expanded</td>
</tr>
</tbody>
</table>

---

604  PowerBuilder

**Return value**

Returns 1 if the expand operation succeeds and one of the following negative values if it fails:

-1  DataWindow is null

-5  One or more of the parameters are invalid

-16  DataWindow is not a TreeView DataWindow

**Usage**

A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the ExpandAllChildren method to expand a group with a specified TreeView level in a TreeView DataWindow and all of its children.

The ExpandAllChildren method triggers the Expanding and Expanded events.

**Examples**

The following example expands the group in a TreeView DataWindow that has TreeView level 2 and includes row 3; it also expands all the group’s children:

```powerbuilder
integer li_ret
li_ret = dw_treeview.ExpandAllChildren(3,2)
```

**See also**

CollapseAllChildren

Expand

ExpandAll

ExpandLevel

IsExpanded

---

**ExpandLevel**

**Description**

Expands all the groups in a TreeView DataWindow that have the specified TreeView level.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
Integer dw_control.ExpandLevel (long groupLevel)
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dw_control</td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
<tr>
<td>groupLevel</td>
<td>The TreeView level of the group to be expanded</td>
</tr>
</tbody>
</table>
**Filter**

**Return value**
Returns 1 if the ExpandLevel operation succeeds and one of the following negative values if it fails:

- **-1**  DataWindow is null
- **-5**  One or more of the parameters are invalid
- **-16** DataWindow is not a TreeView DataWindow

**Usage**
A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the ExpandLevel method to expand all the groups in a TreeView DataWindow that have a particular TreeView level. The ExpandLevel method triggers the Expanding and Expanded events with a row argument of –1.

**Examples**
The following example expands all the groups at TreeView level 2:

```powerbuilder
integer li_ret
li_ret = dw_treeview.ExpandLevel(2)
```

**See also**
CollapseLevel
Expand
ExpandAll
ExpandAllChildren
IsExpanded

**Filter**

**Description**
Displays rows in a DataWindow that pass the current filter criteria. Rows that do not meet the filter criteria are moved to the filter buffer.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

- **PowerBuilder**

  ```powerbuilder
  integer dwcontrol.Filter ()
  ```

- **Web DataWindow server component**

  ```powerbuilder
  short dwcontrol.Filter ()
  ```
Web ActiveX

number dwcontrol.Filter ( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. The return value is usually not used.

If dwcontrol is null, in PowerBuilder and JavaScript the method returns null.

Usage

Filter causes all rows to be retrieved and then it applies the filter. Even when the Retrieve As Needed option is set, the Filter method retrieves all rows before applying the filter.

Filter uses the current filter criteria for the DataWindow. To change the filter criteria, use the SetFilter method. The SetFilter method is equivalent to using the Filter command on the Rows menu of the DataWindow painter. If you do not call SetFilter to assign or change criteria before calling the Filter method, the DataWindow will default to use the criteria in the object definition.

When the Retrieve method retrieves data for the DataWindow, PowerBuilder applies the filter that was defined for the DataWindow object, if any. You only need to call Filter after you change the filter criteria with SetFilter or if the data has changed because of processing or user input.

Filter has no effect on the DataWindows in a composite report.

Filtering and groups

When you filter a DataWindow with groups, you might need to call GroupCalc after you call Filter.

For information on removing the filter or letting the user specify a filter expression, see SetFilter.

Examples

This statement displays rows in dw_Employee based on its current filter criteria:

```
dw_Employee.SetRedraw(false)
dw_Employee.Filter()
dw_Employee.SetRedraw(true)
```

See also

FilteredCount
RowCount
SetFilter
FilteredCount

Description
Reports the number of rows that are not displayed in the DataWindow because of the current filter criteria.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder and Web DataWindow server component**

```java
long dwcontrol.FilteredCount() {
    // Method body
}
```

**Web ActiveX**

```java
number dwcontrol.FilteredCount() {
    // Method body
}
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

Return value
Returns the number of rows in `dwcontrol` that are not displayed because they do not meet the current filter criteria. Returns 0 if all rows are displayed and -1 if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

Usage
A DataWindow object can have a filter as part of its definition. After the DataWindow retrieves data, the filter is applied and rows that do not meet the filter criteria are moved to the filter buffer. You can change the filter criteria by calling the `SetFilter` method, and you can apply the new criteria with the `Filter` method.

Examples
These statements retrieve data in `dw_Employee`, display employees with area code 617, and then test to see if any other data was retrieved. If the filter criteria specifying the area code was part of the DataWindow definition, it would be applied automatically after calling `Retrieve` and you would not need to call `SetFilter` and `Filter`:

```java
dw_Employee.Retrieve()   
dw_Employee.SetFilter("AreaCode=617")  
dw_Employee.SetRedraw(false)  
dw_Employee.Filter()  
dw_Employee.SetRedraw(true)  
```
// Did any rows get filtered out
IF dw_Employee.FilteredCount() > 0 THEN
    ... // Process rows not in area code 617
END IF

These statements retrieve data in dw_Employee and display the number of employees whose names do not begin with B:

dw_Employee.Retrieve()

dw_Employee.SetFilter("Left(emp_lname, 1)="B-"")
dw_Employee.SetRedraw(false)
dw_Employee.Filter()
dw_Employee.SetRedraw(true)

IF dw_Employee.FilteredCount() > 0 THEN
    MessageBox("Employee Count", &
    String(dw_Employee.FilteredCount()) + &
    "Employee names do not begin with B.")
END IF

SetFilter

Find

Description
Finds the next row in a DataWindow or DataStore in which data meets a specified condition.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>
Find

Syntax

**PowerBuilder and Web DataWindow server component**

```java
long dwcontrol.Find ( string expression, long start, long end )
```

**Web DataWindow and Web ActiveX**

```java
number dwcontrol.Find ( string expression, number start, number end )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control, DataStore, or child DataWindow in which you want to search the detail band.</td>
</tr>
<tr>
<td>expression</td>
<td>A string whose value is a boolean expression that you want to use as the search criterion. The expression includes column names.</td>
</tr>
<tr>
<td>start</td>
<td>A value identifying the row location at which to begin the search. Start can be greater than the number of rows.</td>
</tr>
<tr>
<td>end</td>
<td>A value identifying the row location at which to end the search. End can be greater than the number of rows. To search backward, make end less than start.</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of the first row that meets the search criteria within the search range. Returns 0 if no rows are found and one of these negative numbers if an error occurs:

-1 General error
-5 Bad argument

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

**PowerBuilder environment**

For use with a RichTextEdit control or presentation style, see Find in the PowerScript Reference.

The search is case sensitive. When you compare text to a value in a column, the case must match.

**When the Find expression includes quotes** If the text you want to find includes quotes, you must treat the nested quote as doubly nested, because the DataWindow parses the string twice before the Find method uses it. Therefore, you cannot simply alternate double and single quotes, as you can in most strings.

For example, to find the name O’Connor, the Find expression can be:

"O~~~'Connor" (3 tildes and single quote) or
"O~~~~~"Connor" (5 tildes and double quote)
but not:
"O’Connor" or "O~"OConnor"

**When the last row satisfies the search criteria**  If you use Find in a loop that searches through all rows, you may end up with an endless loop if the last row satisfies the search criteria. When the start value becomes greater than end, the search reverses direction and Find would always succeed, resulting in an endless loop.

To solve this problem, you could make the end value 1 greater than the number of rows (see the examples). Another approach, shown below, would be to test within the loop whether the current row is greater than the row count and, if so, exit. This PowerBuilder code illustrates how:

```powerbuilder
long ll_find = 1, ll_end
ll_end = dw_main.RowCount()
ll_find = dw_main.Find(searchstr, ll_find, ll_end)
do while ll_find > 0
    ... // Collect found row
    ll_find++
    // Prevent endless loop
    if ll_find > ll_end then exit
    ll_find = dw_main.Find(searchstr, ll_find, ll_end)
loop
```

### Examples

This statement searches for the first row in dw_status in which the value of the emp_salary column is greater than 100,000. The search begins in row 3 and continues until it reaches the last row in dw_status:

```powerbuilder
long ll_found
ll_found = dw_status.Find("emp_salary > 100000", & 3, dw_status.RowCount())
```

To test values in more than one column, use boolean operators to join conditional expressions. The following statement searches for the employee named Smith whose salary exceeds 100,000:

```powerbuilder
long ll_found
ll_found = dw_status.Find( &
    "emp_lname = 'Smith' and emp_salary > 100000", & 1, dw_status.RowCount())
```
These statements search for the first row in dw_emp that matches the value that a user entered in the SingleLineEdit called Name (note the single quotes embedded in the search expression around the name):

```
string ls_lname_emp
long ll_nbr, ll_foundrow

ll_nbr = dw_emp.RowCount()
// Remove leading and trailing blanks.
ls_lname_emp = Trim(sle_Name.Text)

ll_foundrow = dw_emp.Find( &
    "emp_lname = '' + ls_lname_emp + '"', 1, ll_nbr)
```

This script excerpt finds the first row that has a null value in emp_id. If no null is found, the script updates the DataWindow object. If a null is found, it displays a message:

```
IF dw_status.AcceptText() = 1 THEN
    IF dw_status.Find("IsNull(emp_id)"), &
        1, dw_status.RowCount()) > 0 THEN
        MessageBox("Caution", "Cannot Update")
    ELSE
        dw_status.Update()
    END IF
ENDIF
```

The following script attached to a Find Next command button searches for the next row that meets the specified criteria and scrolls to that row. Each time the button is clicked, the number of the found row is stored in the instance variable il_found. The next time the user clicks Find Next, the search continues from the following row. When the search reaches the end, a message tells the user that no row was found. The next search begins again at the first row.

Note that although the search criteria are hard-coded here, a more realistic scenario would include a Find button that prompts the user for search criteria. You could store the criteria in an instance variable, which Find Next could use:

```
long ll_row

// Get the row num. for the beginning of the search
// from the instance variable, il_found
ll_row = il_found
```
// Search using predefined criteria
ll_row = dw_main.Find( &
   "item_id = 3 or item_desc = 'Nails'", &
   ll_row, dw_main.RowCount())

IF ll_row > 0 THEN
   // Row found, scroll to it and make it current
   dw_main.ScrollToRow(ll_row)
ELSE
   // No row was found
   MessageBox("Not Found", "No row found.")
END IF

// Save the number of the next row for the start
// of the next search. If no row was found,
// ll_row is 0, making il_found 1, so that
// the next search begins again at the beginning
il_found = ll_row + 1

This example searches all the rows in dw_main and builds a list of the names that include a lowercase a. Note that the end value of the search is one greater than the row count, avoiding an infinite loop if the name in the last row satisfies the search:

long ll_find, ll_end
string ll_list

// The end value is one greater than the row count
ll_end = dw_main.RowCount() + 1
ll_find = 1
ll_find = dw_main.Find("Pos(last_name,'a') > 0", &
   ll_find, ll_end)

DO WHILE ll_find > 0
   //collect names
   ll_list = ll_list + '~r' &
      + dw_main.GetItemString(ll_find,'last_name')

   // Search again
   ll_find++
   ll_find = dw_main.Find("Pos(last_name,'a') &
      > 0", ll_find, ll_end )
LOOP

See also
FindGroupChange
FindRequired
FindGroupChange

Description

Searches for the next break for the specified group. A group break occurs when the value in the column for the group changes. FindGroupChange reports the row that begins the next section.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

long dwcontrol.FindGroupChange (long row, integer level)

Web DataWindow server component

long dwcontrol.FindGroupChange (long row, short level)

Web ActiveX

number dwcontrol.FindGroupChange (number row, number level)

Argument | Description
----------|--------------------------------------------------
dwcontrol | A reference to a DataWindow control or the DataStore.
row       | A value identifying the row at which you want to begin searching for the group break.
level     | The number of the group for which you are searching. Groups are numbered in the order in which you defined them.

Return value

Returns the number of the row whose group column has a new value, meaning that it begins a new group. Returns 0 if the value in the group column did not change and a negative number if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

The return value observes these rules based on the value of row. If the starting row is:

- The first row in a group, then FindGroupChange returns the starting row number
- A row within a group, other than the last group, then FindGroupChange returns the row number of the first row of the next group
- A row in the last group, other than the first row of the last group, then FindGroupChange returns 0
CHAPTER 9   Methods for the DataWindow Control

Usage
If the starting row begins a new section at the specified level, then that row is
the one returned. To continue searching for subsequent breaks, increment the
starting row so that the search resumes with the second row in the group.

Examples
This statement searches for the first break in group 2 in dw_regions. The search
begins in row 5:

   dw_regions.FindGroupChange(5, 2)

This code finds the number of the row at which a break occurs in group 1. It
then checks whether the department number is 121. The search begins at row 0:

   boolean lb_found
   long ll_breakrow
   lb_found = false
   ll_breakrow = 0

   DO WHILE NOT (lb_found)
       ll_breakrow = dw_1.FindGroupChange(ll_breakrow, 1)
       // If no breaks are found, exit.
       IF ll_breakrow <= 0 THEN EXIT
       // Have we found the section for Dept 121?
       IF dw_1.GetItemNumber(ll_breakrow, &
           "dept_id") = 121 THEN
           lb_found = true
       END IF
       // Increment starting row to find next break
       ll_breakrow = ll_breakrow + 1
   LOOP

   IF lb_found = false THEN
       MessageBox( &
           "Not Found", &
           "The Department was not found.")
   ELSE
       ... // Processing for Dept 121
   END IF

Find
FindRequired
FindNext

Description
Finds the next occurrence of text in a RichTextEdit DataWindow control and highlights it, using criteria set up in a previous call of the Find method.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
ingenretrint dwcontrol.FindNext()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control containing a DataWindow with the RichTextEdit presentation style</td>
</tr>
</tbody>
</table>

Return value
Returns the number of characters found. FindNext returns 0 if no matching text is found and -1 if the DataWindow’s presentation style is not RichTextEdit or an error occurs.

Usage

**PowerBuilder environment**
For use with PowerBuilder RichTextEdit controls, see FindNext in the *PowerScript Reference*.

Examples

This example searches the DataWindow control dw_1 for text the user specifies in the SingleLineEdit sle_search. The search proceeds forward from the cursor position, is case-insensitive, and is not limited to whole words:

```powerbuilder
genereint li_charsfound
li_charsfound = dw_1.Find(sle_search.Text, &
true, true, false, true)
```

A second button labeled Find Next would have a script like this:

```powerbuilder
dw_1.FindNext()
```

Find
**FindRequired**

**Description**
Reports the next row and column that is required and contains a null value. The method arguments that specify where to start searching also store the results of the search. You can speed up the search by specifying that FindRequired check only inserted and modified rows.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
integer dwcontrol.FindRequired ( DWBuffer dwbuffer, long row, integer colnbr, string colname, boolean updateonly )
```

**Web ActiveX**

```
number dwcontrol.FindRequired ( number dwbuffer, number row, number colnbr, string colname, boolean updateonly )
```

**Argument** | **Description**
--- | ---
**dwcontrol** | A reference to the DataWindow control or DataStore in which you want to find required columns that have null values.

**dwbuffer** | A value indicating the DataWindow buffer you want to search for required columns. Valid buffers are:
- Primary!
- Filter!

**row** | A value identifying the first row to be searched. Row also stores the number of the found row. FindRequired increments the row number automatically after it validates each row’s columns. When it finds a row with a required column that contains a null value, the row number is stored in row. After FindRequired validates the last column in the last row, it sets row to 0.

**PowerBuilder** The row argument must be a variable so it can return a value for the found row.

**colnbr** | A value identifying the first column to be searched. Colnbr also stores the number of the found column. After validating the last column, FindRequired sets colnbr to 1 and increments row. When it finds a required column that contains a null value, the column number is stored in colnbr.

**PowerBuilder** The colnbr argument must be a variable so it can return a value for the found column.
FindRequired

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colname</td>
<td>A string in which you want to store the name of the required column that contains a null value. colnbr must be a variable. <strong>PowerBuilder</strong> The colname argument must be a variable so it can hold a value for the name of the found column.</td>
</tr>
<tr>
<td>updateonly</td>
<td>A value indicating whether you want to validate all rows and columns or only rows that have been inserted or modified:</td>
</tr>
<tr>
<td></td>
<td>• true – Validate only those rows that have changed. Setting updateonly to true enhances performance in large DataWindows.</td>
</tr>
<tr>
<td></td>
<td>• false – Validate all rows and columns.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if FindRequired successfully checked the rows and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

For FindRequired to report an empty required column, the column’s value must actually be null, not an empty string.

To make a column required, set the Required property to true in a script or check the Required check box for the column in the DataWindow painter.

New rows have null values in their columns, unless the columns have default values. If updateonly is false, FindRequired reports empty required columns in new rows. If updateonly is true, FindRequired does not check new rows because new, empty rows are not updated in the database.

When the user modifies a row and leaves a column empty, the new value is an empty string, unless the column’s edit style has the Empty String Is null check box checked. FindRequired does not report empty required columns in modified rows unless this property is set.

Examples

The following code makes a list of all the row numbers and column names in dw_1 in which required columns are missing values. The list is displayed in the MultiLineEdit mle_required:

```plaintext
long ll_row = 1
integer colnbr = 0
string colname

mle_required.Text = ""
DO WHILE ll_row <> 0
   colnbr++ // Continue searching at next column
   // If there's an error, exit
   IF dw_1.FindRequired(Primary!, &
```
This example is a function that ensures that no required column in a DataWindow control is empty (contains null). It takes one argument—the DataWindow control, which is declared in the function declaration like this:

```
DataWindow adw_control
```

The function returns –2 if the user’s last entry cannot be accepted or if FindRequired returns an error. It returns –1 if an empty required column is found. It returns 1 if all required columns have data:

```pascal
integer li_colnbr = 1
long ll_row = 1
string ls_colname, ls_textname

// Make sure the last entry is accepted
IF adw_control.AcceptText() = -1 THEN
    adw_control.SetFocus()
    RETURN -2
END IF

// Find the first empty row and column, if any
IF adw_control.FindRequired(Primary!, ll_row, &
    li_colnbr, ls_colname, true) < 1 THEN
    // If search fails due to error, then return
    RETURN -2
END IF

// Was any row found?
IF ll_row <> 0 THEN
    // Get the text of that column's label.
    ls_textname = ls_colname + "_t.Text"
    ls_colname = adw_control.Describe(ls_textname)

    // Tell the user which column to fill in
```
FindRequiredColumn

Description

Returns the column number that the FindRequired method found. The column is being reported because it is a required column but contains a null value. You must call FindRequired first to search for the required but missing information.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

Web ActiveX

    number dwcontrol.FindRequiredColumn( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control for which you just called FindRequired</td>
</tr>
</tbody>
</table>
Return value

Returns the number of a column in the DataWindow.

Usage

FindRequiredColumn, FindRequiredColumnName, and FindRequiredRow can all be called after FindRequired to identify rows and columns with missing data. For details, see FindRequired on page 617.

FindRequiredColumnName

Description

Returns the column name that the FindRequired method found. The column is being reported because it is a required column but contains a null value. You must call FindRequired first to search for the required but missing information.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

Web ActiveX

string dwcontrol.FindRequiredColumnName ( )

Argument | Description
----------|-----------------|
dwcontrol | A reference to the DataWindow control for which you just called FindRequired

Return value

Returns the name of a column in the DataWindow.

Usage

FindRequiredColumn, FindRequiredColumnName, and FindRequiredRow can all be called after FindRequired to identify rows and columns with missing data. For details, see FindRequired on page 617.

FindRequiredColumn
FindRequiredColumnName
**Generate**

**Description**

Creates HTML syntax for the Web DataWindow.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

**Syntax**

```csharp
Web DataWindow server component

string dwcontrol.Generate ()
```

**Return value**

Returns an HTML rendering of the current page of the DataWindow if the method succeeds and an empty string if an error occurs.

**Usage**

Call this method to create HTML syntax from the DataWindow defined for the server component. The `Generate` method is usually called by a server-side script running on a page server. The page server creates the complete Web page by combining the return value with other appropriate HTML elements.

The contents of the page of data can be affected by user actions in the client control. The page server calls the `SetAction` method before calling `Generate` to apply the user’s actions.

The `Generate` method causes DataWindow columns to be rendered as HTML INPUT elements with the following exceptions:

- A column to which you assign a hyperlink. The hyperlink is valid only if the column tab order is set to 0, its Protect property is set to 1, or if it has an `Edit.DisplayOnly` property that is set to “yes”. A column with a valid hyperlink is rendered in an `<A HREF>` tag.
- A column for which the `ValueIsHTML` property is set to true. The column value can be plain text or some combination of HTML tags and plain text. The column value is included unchanged within the generated HTML page.
- A column with a DropDownListBox or DropDownDW edit style. Columns with these edit styles are always rendered in `<SELECT>` tags.
- Computed fields that are not dynamically calculated on the client. Computed fields are rendered as HTML INPUT elements only if the `ClientComputedFields` property for the DataWindow is set to “yes”. Otherwise they are rendered as text.
If the column has a validation rule, it is translated to JavaScript if possible. Parts of the DataWindow object included in the generated HTML are:

- Columns, computed fields, text controls
- Pictures (picture format should be GIF or JPEG)
- Buttons
- Page headers and footers
- Group headers and trailers
- Summary bands
- Display formats, validation rules, edit styles (EditMasks are converted to display formats)

DataWindow features that will not be rendered into HTML include:

- Graph, OLE, and RichText presentation styles and controls
- Drawing controls (lines, circles, rectangles)
- Client-side expressions that include aggregate functions. Such expressions will be computed on the server
- Resizable and movable controls
- Sliding of controls to fill empty space
- Autosizing of height or width

**Examples**

The following example generates a DataWindow object in HTML:

```javascript
dwGen.Generate();
```

GenerateHTMLForm

Description
Creates an HTML Form element containing columns for one or more rows in a DataWindow control or DataStore. This method also returns an HTML Style element containing style sheet information.

Obsolete method
GenerateHTMLForm is obsolete and should not be used.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

integer dwcontrol.GenerateHTMLForm ( string syntax, string style, string action [, long startrow, long endrow, integer startcolumn, integer endcolumn [, DWBuffer buffer ] ] )

Return value
Returns 1 if the method succeeds and –1 if an error occurs.
If any argument is null, the method returns null.

GenerateResultSet

Generates a result set that can be used by non-DataWindow controls for displaying data. A result set is usually generated by a component on a transaction server and returned to a client application.

<table>
<thead>
<tr>
<th>To generate a result set</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>That can be an EAServer result set or an ADO Recordset</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>Using an EAServer Method As Stored Procedure (MASP)</td>
<td>Syntax 2</td>
</tr>
</tbody>
</table>

Syntax 1

For generating an EAServer result set or an ADO Recordset

Description
Generates a result set from data in a DataStore or DataWindow control.

In PowerBuilder, when the result set is generated in a component on a transaction server, the format of the result set is determined by the server—TabularResults in EAServer and ADO Recordset on MTS.
**GenerateResultSet**

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataStore object</td>
</tr>
</tbody>
</table>

### Syntax

**PowerBuilder**

```
integer dsobject.GenerateResultSet (REF ResultSet rsdest { ,dwBuffer dwbuffer })
```

### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dsobject</td>
<td>The name of the DataStore object that contains the data to be returned in the result set.</td>
</tr>
<tr>
<td>rsdest</td>
<td>The ResultSet object into which the data in the DataStore is written. This value is passed by reference.</td>
</tr>
<tr>
<td>dwbuffer</td>
<td>A value of the dwBuffer enumerated datatype identifying the DataWindow buffer containing the data for the result set. The default is the primary buffer.</td>
</tr>
<tr>
<td></td>
<td>For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>

### Return value

Returns 1 if it succeeds and –1 if it fails. If any argument is null, it returns null.

### Usage

**How to use it**  
Result sets are intended for exchanging data between a DataStore and some data-aware application that does not use DataWindow technology. With result sets, the receiving end does not support updating of the data.

The `GenerateResultSet` method is typically used in a PowerBuilder custom class user object that has been packaged as a component on EAServer or on an MTS server. A function in the user object generates a result set from information that has been retrieved into a DataStore. The function then returns the result set or passes it to another method.

For example, a function for PowerBuilder custom class user object running in a transaction server can retrieve data into a DataStore object, create a result set object, and return the result set. A client application calls the function to get the data. The client application must be able to handle result sets, but it does not need to have support for DataWindow technology.

Likewise, a client application can generate a result set from a DataStore and pass the result set to the server.

The `CreateFrom` method can convert a result set back to a DataStore.
**Result set format**  The result set is returned to a client in a format that is standard for the server. In user objects deployed to EAServer, user-defined functions that return a PowerBuilder ResultSet object are represented in the IDL definition of the component as methods that return a result set of type TabularResults::ResultSet. Multiple result sets returned in a ResultSets object are represented in the IDL as TabularResults::ResultSets datatypes. In MTS, returning a result set created by GenerateResultSet causes an ADO Recordset to be marshaled to the client.

The GenerateResultSet method can also be called in a client application. Since the format of the result set depends on the server on which it is used, the format is fixed when that result set is passed to a server. For EAServer, the format is TabularResults::ResultSet; for MTS, the format is an ADO Recordset.

**Destroying or modifying the DataStore**  The generated ResultSet object maintains a reference to the DataStore from which it was generated, so changes made to the DataStore object after the result set is generated will be reflected in the generated ResultSet object. If you destroy the DataStore object before returning the result set, the result set becomes invalid. You can rely on garbage collection to destroy the DataStore object or destroy it explicitly in the component’s deactivate event.

**Other data exchange techniques**  To exchange data between a DataWindow on a client and a DataStore on EAServer, use the data-synchronizing methods GetFullState and SetFullState. With these methods, both controls remain updatable. If updating is not a concern, you still might choose result sets instead of synchronizing methods because result sets transfer less data.

**Examples**

In this example, a DataStore object is created and data is retrieved into it, and then the GenerateResultSet method is used to create a result set that can be returned to a client.

```powerbuilder
datastore ds_datastore
resultset lrs_resultset
integer li_rc

ds_datastore = CREATE DataStore
ds_datastore.SetTransObject (SQLCA)
IF ds_datastore.Retrieve() = -1 THEN
    ... // report error and return
END IF

li_rc = ds_datastore.GenerateResultSet(lrs_resultset)
IF li_rc <> 1 THEN
```

DataWindow Reference 627
GenerateResultSet

... // report error and return
END IF
return lrs_resultset

See also
CreateFrom
SetRecordSet in PowerScript Reference

Syntax 2
For generating a result set using an EAServer Method As Stored Procedure

Description
Generates an EAServer result set that can be returned from a PowerBuilder user object running as a component on EAServer. The result set is retrieved using a DataWindow control or DataStore object whose data source is an EAServer component method.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder
dwcontrol.GenerateResultSet ()

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The DataWindow control or DataStore object that contains the data to be returned in the result set.</td>
</tr>
<tr>
<td>dwbuffer</td>
<td>A value of the dwBuffer enumerated datatype specifying the DataWindow buffer from which you want to copy rows. Valid values are:</td>
</tr>
<tr>
<td>(optional)</td>
<td>• Primary! – (Default) The data in the primary buffer (data that has not been deleted or filtered out).</td>
</tr>
<tr>
<td></td>
<td>• Delete! – The data in the delete buffer (data deleted from the DataWindow object).</td>
</tr>
<tr>
<td></td>
<td>• Filter! – The data in the filter buffer (data that was filtered out).</td>
</tr>
</tbody>
</table>

Return value
Returns 1 if it succeeds or one of the following negative values if an error occurs:

-4 Value of dwbuffer or internal parameter incorrect
-10 Calling object not running on EAServer or EAServer API library could not be loaded
-11 Entry points in EAServer API library not found
-12 Internal error
Usage

The GenerateResultSet method allows you to return a result set from a PowerBuilder custom class user object that has been packaged as a component on EAServer using the EAServer Method As Stored Procedure (MASP) technique. For more information about MASP, see the EAServer and PowerDynamo documentation.

GenerateResultSet does not return a result set if the custom class user object is not running on EAServer.

To use GenerateResultSet, create a user object function for the custom class user object that will be installed on EAServer. The user object function must not return a value. It connects to a database and retrieves data into a DataStore object using the PowerBuilder Transaction object. The call to GenerateResultSet uses column data in the DataStore object to generate an EAServer result set.

In the installed EAServer component, the user object function runs as a method on EAServer. EAServer can return the generated result set to any client that can interpret a Tabular Data Stream (TDS) result set. To retrieve the result set from a PowerBuilder client, create a DataWindow object whose data source is Stored Procedure and select the method on EAServer as the data source.

DataWindow datatypes map to CS-Library type constants in the result set as follows:

<table>
<thead>
<tr>
<th>DataWindow datatype</th>
<th>Datatype in result set</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date</td>
<td>CS_CHAR_TYPE</td>
</tr>
<tr>
<td>DateTime</td>
<td>CS_DATETIME_TYPE</td>
</tr>
<tr>
<td>Decimal</td>
<td>CS_DECIMAL_TYPE</td>
</tr>
<tr>
<td>Long, Ulong</td>
<td>CS_INT_TYPE</td>
</tr>
<tr>
<td>Number</td>
<td>CS_FLOAT_TYPE</td>
</tr>
<tr>
<td>Real</td>
<td>CS_REAL_TYPE</td>
</tr>
<tr>
<td>String (length &lt;= 244)</td>
<td>CS_CHAR_TYPE</td>
</tr>
<tr>
<td>String (length &gt; 244)</td>
<td>CS_LONGCHAR_TYPE</td>
</tr>
<tr>
<td>Time</td>
<td>CS_CHAR_TYPE</td>
</tr>
</tbody>
</table>

The precision of all decimal datatypes in the result set will be 16.

The sort order of the result set remains the same whether or not the method running on EAServer performs a sort operation on the DataStore object. If the result set is returned to a PowerBuilder client, you can use the Sort and SetSort PowerScript methods to sort the returned data.
If `GenerateResultSet` is called multiple times within a single script, EAServer passes multiple duplicate result sets back to the client.

The following is a user object function that runs as a method on EAServer. The function creates an instance of a DataStore object, connects to a database, and retrieves data into the DataStore object. The call to `GenerateResultSet` creates an EAServer result set that is returned to the client from the data in the DataStore object.

```powershell
// User object function: uf_gettraintimes
// Set transaction object properties
...
// Open a log file for connect errors
integer li_FileNum
li_FileNum = FileOpen("C:\SCHEDULES\ERRORS.TXT", &
    LineMode!, Write!, LockWrite!, Append!)

// Connect to the database
CONNECT using SQLCA;
IF SQLCA.SQLCode <>0 THEN
    FileWrite(li_FileNum, &
        "Cannot connect to database " &
        + SQLCA.SQLErrText)
    RETURN
ELSE

    // Create a DataStore object and retrieve data
    uo_ds_traintimes u_DataStore
    u_DataStore = CREATE uo_ds_traintimes
    u_DataStore.SetTransObject(sqlca)
    u_DataStore.Retrieve()

    // Generate the result set
    long ll_return
    ll_return = &
        u_DataStore.GenerateResultSet(Primary!)
    IF ll_return <> 1 THEN
        FileWrite(li_FileNum, &
            "GenerateResultSet return code: " &
            + string(ll_return))
    ELSE
        FileWrite(li_FileNum, "Result set generated")
    END IF
```
To use the method above with a PowerBuilder client, start PowerBuilder and connect with ODBC or with the SYC database interface to EAServer where the user object is installed. Create a new DataWindow object with Stored Procedure as its data source and then select the component method from the list of stored procedures. Define the result set to correspond to the result set returned by the method on the server.

In the client application, use the `Retrieve` method to retrieve data from the server:

```powershell
// The data source for dw_traintimes is
// PBPackage.PBServer.uf_gettraintimes
dw_traintimes.Retrieve()
```

---

**GenerateXHTML**

*Description*  
Generates the inline content of the Web DataWindow in XHTML.

*Applies to*  

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

*Syntax*  

**Web DataWindow server component**

```powershell
string dwcontrol.GenerateXHTML ([page] [variables])
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the server-side DataWindow control you want to generate in XHTML.</td>
</tr>
<tr>
<td><code>page</code></td>
<td>An array for passing page variables. The page variables must be defined as String datatypes.</td>
</tr>
</tbody>
</table>

*Return value*  
Integer. 1 indicates success, and –1 indicates failure.

*Usage*  
At runtime, `GenerateXHTML` performs the tasks required to generate the dynamic XHTML, including retrieving the action context and generating the XHTML inline. Connection errors, including database error messages, are also generated inline.
For information about the advantages and limitations of each rendering format, see the *DataWindow Programmers Guide*.

The GenerateXHTML method delivers the DataWindow in XHTML to the client browser and it generates a CSS style sheet and JS files that are cached on the client side and referenced in the XHTML source.

**Examples**

The following JSP example specifies subdirectories of the current application directory to publish the CSS and JS components of the Web DataWindow and generates the DataWindow in XHTML:

```java
String resourceBase = request.getScheme() + "://" +
    request.getServerName() + ":" +
    request.getServerPort() + request.getContextPath();

String publishPath = application.getRealPath("/");

dwGen.Modify("DataWindow.CSSGen.ResourceBase = " +
    resourceBase + "/css");

dwGen.Modify("DataWindow.CSSGen.PublishPath = " +
    publishPath + "css");

dwGen.Modify("DataWindow.JSGen.ResourceBase = " +
    resourceBase + "/js");

dwGen.Modify("DataWindow.JSGen.PublishPath = " +
    publishPath + "js");

String dwXHTML = dwGen.GenerateXHTML();
out.print (dwXHTML);
```

Generate
GenerateXMLWeb

---

**GenerateXMLWeb**

**Description**

Generates the XML content and the XSLT and CSS style sheets for a Web DataWindow, which is transformed to XHTML on the client side.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

---
**Web DataWindow server component**

```java
string dwcontrol.GenerateXMLWeb (page [ ] variables)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the server-side DataWindow control</td>
</tr>
<tr>
<td>page</td>
<td>An array for passing page variables. The page variables must be defined as String datatypes.</td>
</tr>
</tbody>
</table>

**Return value**

Integer. 1 indicates success, and –1 indicates failure.

**Usage**

The `GenerateXMLWeb` function uses the resource base and publish paths for a DataWindow object to determine where it generates XML, XSLT, CSS, and JS files. If a resource base or a publish path is not specified for a DataWindow object, the `GenerateXMLWeb` function creates a TEMP directory on the server where the XML, XSLT, CSS, and JS files are stored.

At design time, you can override the resource base and publish paths by making `Modify` calls on the DataWindow object in the Source view before you call `GenerateXMLWeb`. The following example creates separate subdirectories for XML, XSLT, CSS, and JS files:

```java
String resourceBase = request.getScheme() + "://" +
    request.getServerName() + ":" +
    request.getServerPort() + request.getContextPath();

String publishPath = application.getRealPath("/");

dwGen.Modify("DataWindow.XMLGen.ResourceBase = "+
    resourceBase + "/xml");

dwGen.Modify("DataWindow.XMLGen.PublishPath = "+
    publishPath + "xml");

dwGen.Modify("DataWindow.XSLTGen.ResourceBase = "+
    resourceBase + "/xsl");

dwGen.Modify("DataWindow.XSLTGen.PublishPath = "+
    publishPath + "xsl");

dwGen.Modify("DataWindow.CSSGen.ResourceBase = "+
    resourceBase + "/css");

dwGen.Modify("DataWindow.CSSGen.PublishPath = "+
    publishPath + "css");

dwGen.Modify("DataWindow.JSGen.ResourceBase = "+
```
resourceBase + "/js");

dwGen.Modify("DataWindow.JSGen.PublishPath = " +
   publishPath + "/js");

At runtime, the client browser displays an XHTML page that it transforms from XML using XSLT applied with CSS and JS files that it gets initially from the server. However, in most cases, after the initial loading of the page, the client does not need to go back to the server to obtain layout (XSLT) or styling (CSS) information, as these remain in the browser’s cache. This provides greater efficiency and scalability for your Web applications.

Examples
In the following example, the Web DataWindow component generates the XML document, XSLT and CSS style sheets, and JS files for the content, structure, styling, and client-side functionality of the Web DataWindow:

dwGen. GenerateXMLWeb();

Generate
GenerateXHTML

GetBandAtPointer

Description
Reports the band in which the pointer is currently located, as well as the row number associated with the band. The bands are the headers, trailers, and detail areas of the DataWindow and correspond to the horizontal areas of the DataWindow painter.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
string dwcontrol.GetBandAtPointer()
```

**Web ActiveX**

```
string dwcontrol.GetBandAtPointer()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control.</td>
</tr>
</tbody>
</table>
Return value

Returns a string that names the band in which the pointer is located, followed by a tab character and the number of the row associated with the band (see the table in Usage). Returns the empty string (""") if an error occurs.

If dwcontrol is null, the method returns null.

Usage

The following table lists the band names, where the pointer is when a given band is reported, and the row that is associated with the band.

<table>
<thead>
<tr>
<th>Band</th>
<th>Location of pointer</th>
<th>Associated row</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail</td>
<td>In the body of the DataWindow object</td>
<td>The row at the pointer. If rows do not fill the body of the DataWindow object because of a group with a page break, then the first row of the next group. If the body is not filled because there are no more rows, then the last row.</td>
</tr>
<tr>
<td>header</td>
<td>In the header of the DataWindow object</td>
<td>The first row visible in the DataWindow body.</td>
</tr>
<tr>
<td>header.n</td>
<td>In the header of group level n</td>
<td>The first row of the group.</td>
</tr>
<tr>
<td>trailer.n</td>
<td>In the trailer of group level n</td>
<td>The last row of the group.</td>
</tr>
<tr>
<td>footer</td>
<td>In the footer of the DataWindow object</td>
<td>The last row visible in the DataWindow body.</td>
</tr>
<tr>
<td>summary</td>
<td>In the summary of the DataWindow object</td>
<td>The last row before the summary.</td>
</tr>
</tbody>
</table>

You can parse the return value by searching for the tab character (ASCII 09). In PowerBuilder, search for ~t. For an example that parses a string that includes a tab, see GetValue.

Examples

These statements set the string named band to the location of the pointer in DataWindow dw_rpt:

```powershell
String band
band = dw_rpt.GetBandAtPointer()
```
**GetBorderStyle**

Some possible return values are:

<table>
<thead>
<tr>
<th>Return value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail[tab]8</td>
<td>In row 8 of the detail band of dw_rpt</td>
</tr>
<tr>
<td>header[tab]10</td>
<td>In the header of dw_rpt; row 10 is the first visible row</td>
</tr>
<tr>
<td>header.2[tab]1</td>
<td>In the header of group level 2 for row 1</td>
</tr>
<tr>
<td>trailer.1[tab]5</td>
<td>In the trailer of group level 1 for row 5</td>
</tr>
<tr>
<td>footer[tab]111</td>
<td>In the footer of dw_rpt; the last visible row is 111</td>
</tr>
<tr>
<td>summary[tab]23</td>
<td>In the summary of dw_rpt; the last row is 23</td>
</tr>
</tbody>
</table>

See also GetObjectAtPointer

---

**GetBorderStyle**

**Description**

Reports the border style of a column in a DataWindow control or DataStore object.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
border dwcontrol.GetBorderStyle ( integer column )
border dwcontrol.GetBorderStyle ( string column )
```

**Web ActiveX**

```
number dwcontrol.GetBorderStyle ( number column )
number dwcontrol.GetBorderStyle ( string column )
```

**Argument** | **Description**
---|---
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow.
`column` | The column for which you want to obtain the border style. *Column* can be a column number or a column name.
Return value

Returns the border style of column in dwcontrol as a value of the Border enumerated datatype (PowerBuilder) or as a number (Web ActiveX). For a list of possible values, see Border on page 476.

Returns null if it fails. If any argument is null, the method returns null.

Examples

This code gets the border style for the current column:

```
border B2
```

This code tests the border of column 2 in dw_emp and, if there is no border, displays a shadow box border:

```
border B2
B2 = dw_emp.GetBorderStyle(2)
IF B2 = NoBorder! THEN
    dw_emp.SetBorderStyle(2, ShadowBox!)
END IF
```

See also

SetBorderStyle

---

**GetChanges**

**Description**

Retrieves changes made to a DataWindow or DataStore as a blob. This method is used primarily in distributed applications.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder.**

```
long dwcontrol.GetChanges ( REF blob changeblob , blob cookie )
```

**Web ActiveX.**

```
number dwcontrol.GetChanges ( )
```

**Argument** | **Description**
|--------------|---------------------------------
| `dwcontrol`  | A reference to a DataWindow control or DataStore. |
GetChanges

Returns the number of rows in the DataWindow change blob if it succeeds and one of the following values if it fails:

- **–1** An internal error occurred.
- **–2** There is a conflict between the state of the DataWindow change blob and the state of the DataWindow from which the cookie was created; an attempt to use this blob in a SetChanges call against the DataWindow will fail.
- **–3** There is a conflict between the state of the DataWindow change blob and the state of the DataWindow from which the cookie was created; but partial changes from the change blob can be applied.

If any argument is null, the method returns null.

Usage

GetChanges is used in conjunction with SetChanges to synchronize two or more DataWindows or DataStores. GetChanges retrieves data buffers and status flags for changed rows in a DataWindow or DataStore and places this information in a blob. SetChanges then applies the contents of this blob to another DataWindow or DataStore.

Reapplying changes from one DataWindow (or DataStore) to another

If you call GetChanges on a DataWindow and apply the data passed in the changeblob argument to another DataWindow using SetChanges, you must call GetChanges on the second DataWindow before you reapply changes to it from the first DataWindow. The GetChanges call on the second DataWindow updates the original timestamp on that DataWindow so that it matches the current timestamp. (You cannot use the Reset, ResetUpdate, or AcceptText calls to update the original timestamp.) If you try to reapply changes without first calling GetChanges on the second DataWindow, you will get an error due to the conflict between the state of the DataWindow changeblob and the state of the second DataWindow.

### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changeblob</td>
<td>A variable into which the returned DataWindow changes will be placed. In the Web ActiveX, call GetChangesBlob to access the blob instead of using the reference variable.</td>
</tr>
<tr>
<td>cookie (obsolete)</td>
<td>A read-only blob created by GetStateStatus that is compared with the changeblob to determine the likely success of a subsequent call to SetChanges. This argument is obsolete and will be disabled in a future release.</td>
</tr>
</tbody>
</table>

Return value

Usage GetChanges is used in conjunction with SetChanges to synchronize two or more DataWindows or DataStores. GetChanges retrieves data buffers and status flags for changed rows in a DataWindow or DataStore and places this information in a blob. SetChanges then applies the contents of this blob to another DataWindow or DataStore.
The change blob created by GetChanges includes only those rows that have a status of New!, NewModified!, or DataModified!.

For information about status values, see DWItemStatus on page 479.

Examples

These statements use GetChanges to capture changes to a DataWindow control on a client. If GetChanges succeeds, the client calls a remote object function that applies the changes to a DataStore on the server and updates the database:

```c
blob lblb_changes
long ll_rv

ll_rv = dw_employee.GetChanges(lblb_changes)

IF ll_rv = -1 THEN
    MessageBox("Error", "GetChanges call failed!")
ELSE
    iuo_employee.UpdateData(lblb_changes)
END IF
```

GetFullState
GetStateStatus
SetChanges
SetFullState

---

**GetChangesBlob**

**Description**

Returns changes made to a DataWindow or DataStore. You must call GetChanges first to set up the change information. This method is used primarily in distributed applications.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**Web ActiveX**

```
string dwcontrol.GetChangesBlob ( )
```

**Argument** | **Description**
---|---
`dwcontrol` | A reference to the DataWindow control for which you just called GetChanges
GetChild

Return value

Returns a string whose value is the DataWindow change blob set up by GetChanges. If dwcontrol is null, the method returns null.

Usage

GetChanges and GetChangesBlob are used in conjunction with SetChanges to synchronize two or more DataWindows or DataStores. For details, see GetChanges.

Examples

These statements use GetChanges to capture changes to a DataWindow control on a client. If GetChanges succeeds, the client calls a remote object function that applies the changes to a DataStore on the server and updates the database:

```
blob lblob_changes
long ll_rv

ll_rv = dw_employee.GetChanges(lblob_changes)

IF ll_rv = -1 THEN
    MessageBox("Error", "GetChanges call failed!"
ELSE
    iuo_employee.UpdateData(lblob_changes)
END IF
```

See also

GetFullState
GetStateStatus
SetChanges
SetFullState

GetChild

Description

Provides a reference to a child DataWindow or to a report in a composite DataWindow, which you can use in DataWindow functions to manipulate that DataWindow or report.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

For PowerBuilder:

```
integer dwcontrol.GetChild (string name, REF DataWindowChild dwchildvariable )
```
CHAPTER 9  Methods for the DataWindow Control

Web ActiveX

number dwcontrol.GetChild( string name )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control or DataStore that contains the child DataWindow or report.</td>
</tr>
<tr>
<td>name</td>
<td>A string that names the column containing the child DataWindow or that names the report in the composite DataWindow.</td>
</tr>
<tr>
<td>dwchildvariable</td>
<td>A variable in which you want to store the reference to the child DataWindow or report. For the Web ActiveX, the separate function GetChildObject must be called to get the reference variable to the child object.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and –1 if an error occurs—for example, if the child object does not exist.

If any argument is null, in PowerBuilder and JavaScript the method returns null.

Usage

A child DataWindow is a DropDownDataWindow in a DataWindow object.

A report is a DataWindow that is part of a composite DataWindow. A report is read-only. When you define the composite DataWindow in the DataWindow painter, each report is given a name. You can see the name in the Name option of the Properties view. You must use the report name (not the name of the DataWindow object in which the report has been placed) when calling GetChild.

Use GetChild when you need to explicitly retrieve data for a child DataWindow or report. Although PowerBuilder automatically retrieves data for the child or report when the main DataWindow is displayed, you need to explicitly retrieve data when there are retrieval arguments or when conditions change and you want to retrieve new rows.

When you insert a row or retrieve data in the main DataWindow, PowerBuilder automatically retrieves data for the child DataWindow. If the child DataWindow has retrieval arguments, PowerBuilder displays a dialog box asking the user for values for those arguments. To suppress the dialog box, you can explicitly retrieve data for the child before changing the main DataWindow (see the example).

Nested reports

You cannot use GetChild to get a reference to a report in a composite DataWindow when the report itself is a composite or nested DataWindow.
GetChild

Changing property values with the Modify method can cause the reference returned by GetChild to become invalid. After setting such a property, call GetChild again. If a property causes this behavior, this is noted in its description in Chapter 3, “DataWindow Object Properties.”

Examples

This example retrieves data for the child DataWindow associated with the column `emp_state` before retrieving data in the main DataWindow. The child DataWindow expects a region value as a retrieval argument. Because you populate the child DataWindow first, specifying a value for its retrieval argument, there is no need for PowerBuilder to display the retrieval argument dialog box:

```powerbuilder
DataWindowChild state_child
integer rtncode

rtncode = dw_1.GetChild('emp_state', state_child)
IF rtncode = -1 THEN MessageBox( &
        "Error", "Not a DataWindowChild")

// Establish the connection
CONNECT USING SQLCA;

// Set the transaction object for the child
state_child.SetTransObject(SQLCA)

// Populate with values for eastern states
state_child.Retrieve("East")

// Set transaction object for main DW and retrieve
dw_1.SetTransObject(SQLCA)
dw_1.Retrieve()
```

In a composite DataWindow there are two reports: orders and current inventory. The orders report has a retrieval argument for selecting the order status. This report displays open orders. The composite DataWindow is displayed in a DataWindow control called `dw_news` and the reports are named `open_orders` and `current_inv`. The following code in the Open event of the window that contains `dw_news` provides a retrieval argument for `open_orders`:

```powerbuilder
DataWindowChild dwc_orders
dw_news.GetChild("open_orders", dwc_orders)
dwc_orders.SetTransObject(SQLCA)
dwc_orders.Retrieve("open")
```
The following example for the Web ActiveX displays the reference to the child object in a message box:

```javascript
var  ls ;
var  ldwc;

window.dw_1.GetChild("dept_id");
ldwc = window.dw_1.GetChildObject();
ls = ldwc.Describe("Datawindow.Table.Select");
window.alert(ls);
```

See also
GetChildObject
SetTransObject

### GetChildObject

**Description**
Gets the reference to a child object for a Web ActiveX DataWindow.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**Web ActiveX**

```javascript
OleObject dwcontrol.GetChildObject ( )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control or DataStore that contains the child DataWindow or report</td>
</tr>
</tbody>
</table>

**Return value**

Returns an object that is the DataWindowChild or report. If no object is found, a null object reference is returned.

**Usage**
You must call GetChild before you call GetChildObject.

**Examples**
The following example displays the reference to the child object in a message box:

```javascript
var  ls ;
var  ldwc;
```
GetClickedColumn

Obtains the number of the column the user clicked or double-clicked in a DataWindow control or DataStore object.

**Syntax**

- **PowerBuilder**
  
  ```powerbuilder
  integer dwcontrol.GetClickedColumn()
  ```

- **Web DataWindow client control and Web ActiveX**
  
  ```javascript
  number dwcontrol.GetClickedColumn()
  ```

**Argument Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore object, or child DataWindow</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of the column that the user clicked or double-clicked in `dwcontrol`. Returns 0 if the user did not click or double-click a column (for example, the user double-clicked outside the data area, in text or spaces between columns, or in the header, summary, or footer area).

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

Call `GetClickedColumn` in the Clicked or DoubleClicked event for a DataWindow control.

When the user clicks on the column, that column becomes the current column after the Clicked or DoubleClicked event is finished. During those events, `GetColumn` and `GetClickedColumn` can return different values.
If the user arrived at a column by another means, such as tabbing, 
GetClickedColumn cannot identify that column. Use GetColumn instead to 
identify the current column.

Examples

These statements return the number of the column the user clicked or double-
clicked in dw_employee:

```powerbuilder
integer li_ColNbr
li_ColNbr = dw_employee.GetClickedColumn()
```

See also

GetClickedRow
GetColumn

---

### GetClickedRow

**Description**

Obtains the number of the row the user clicked or double-clicked in a 
DataWindow control or DataStore object.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

#### PowerBuilder

```powerbuilder
long dwcontrol.GetClickedRow ()
```

#### Web DataWindow client control and Web ActiveX

```javascript
number dwcontrol.GetClickedRow ()
```

**Argument | Description**
--- | ---
`dwcontrol` | A reference to a DataWindow control or DataStore object

**Return value**

Returns the number of the row that the user clicked or double-clicked in 
dwcontrol. Returns 0 if the user did not click or double-click a row (for 
example, the user double-clicked outside the data area, in text or spaces 
between rows, or in the header, summary, or footer area).

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

Call GetClickedRow in the Clicked or DoubleClicked event for a DataWindow 
control.
When the user clicks on the row, that row becomes the current row after the Clicked or DoubleClicked event is finished. During those events, GetRow and GetClickedRow can return different values.

If the user arrived at a row by another means, such as tabbing, GetClickedRow cannot identify that row. Use GetRow instead to identify the current row.

**Not on child DataWindows**
The GetClickedRow method does not work on child DataWindows.

**Examples**
These statements return the number of the row the user clicked or double-clicked in dw_Employee:

```powerbuilder
long li_RowNbr
li_RowNbr = dw_employee.GetClickedRow()
```

See also
GetClickedColumn
GetRow

---

**GetColumn**

**Description**
Obtains the number of the current column. The current column is the column that has focus.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder```
integer dwcontrol.GetColumn ()
```

**Web DataWindow client control and Web ActiveX**

```powerbuilder```
number dwcontrol.GetColumn ()
```

**Web DataWindow server component**

```powerbuilder```
short dwcontrol.GetColumn ()
```

646
**Return value**

Returns the number of the current column in *dwcontrol*. Returns 0 if no column is current (because all the columns have a tab value of 0, making all of them uneditable), and –1 if an error occurs.

If *dwcontrol* is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

GetColumn and GetClickedColumn, when called in the Clicked or DoubleClicked event, can return different values. The column the user clicked does not become current until after the event.

Use GetColumnName (instead of GetColumn) when you need the column’s name. Use SetColumn to change the current column.

**PowerBuilder environment**

For use with PowerBuilder ListView controls, see GetColumn in the PowerScript Reference.

---

**The current column**

A column becomes the current column after the user tabs to it or clicks it or if a script calls the SetColumn method. A column cannot be current if it cannot be edited (if it has a tab value of 0).

A DataWindow always has a current column, even when the control is not active, as long as there is at least one editable column.

**Examples**

These statements return the number of the current column in *dw_Employee*:

```plaintext
integer li_ColNum
li_ColNum = dw_employee.GetColumn()
```

**See also**

GetClickedColumn
GetColumnName
GetRow
SetColumn
SetRow
**GetColumnName**

**Description**
Obtains the name of the current column. The current column is the column that has the focus.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

PowerBuilder, Web DataWindow, and WebActiveX

```plaintext
string dwcontrol.GetColumnName()
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

**Return value**

Returns the name of the current column in `dwcontrol`. Returns the empty string ("") if no column is current or if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

For information on the current column, see GetColumn on page 646.

**Examples**

These statements return the name of the current column in `dw_Employee`:

```plaintext
string ls_ColName
ls_ColName = dw_employee.GetColumnName()
```

**See also**

648
CHAPTER 9  Methods for the DataWindow Control

Syntax

**PowerBuilder**

```
integer objectname.GetContextService(string servicename, PowerObject servicereference)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectname</td>
<td>A reference to an object or control for which you want a service.</td>
</tr>
</tbody>
</table>
| servicename | String specifying the service object. Valid values include:  
  • ContextInformation – Context information service  
  • Internet – Internet service  
  • ContextKeyword – Context keyword service |
| servicereference | PowerObject into which the method places a reference to the service object specified by servicename. This argument is passed by reference. |

Return value

Returns 1 if the method succeeds and –1 if an error occurs.

Usage

Inherited from PowerObject. For information, see GetContextService in the PowerScript Reference.

### GetFormat

**Description**

Obtains the display format assigned to a column in a DataWindow control or DataStore object.

**Separate method name for the Web DataWindow server component**

A separate method, GetFormatByColNum, is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

<table>
<thead>
<tr>
<th>Applies to</th>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td></td>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td></td>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
string dwcontrol.GetFormat(string column)
```

```
string dwcontrol.GetFormat(integer column)
```
Web DataWindow server component

string dwcontrol.GetFormat ( string column )
string dwcontrol.GetFormatByColNum ( short column )

Web ActiveX

string dwcontrol.GetFormat ( string column )
string dwcontrol.GetFormat ( number column )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>column</td>
<td>The column for which you want the display format. Column can be a column number (integer) or a column name (string).</td>
</tr>
</tbody>
</table>

Return value

Returns the display format specification for column in dwcontrol. If an error occurs, GetFormat returns the empty string (""). If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

If you want to change the display format of a column temporarily, you can use GetFormat to save the current format.

Examples

These statements save the format of column salary of dw_employee before changing it to a new format:

```plaintext
string OldFormat, NewFormat = "$##,###.00"
OldFormat = dw_employee.GetFormat("salary")
dw_employee.SetFormat("salary", NewFormat)
```

See also

SetFormat

GetFullContext

Description

This method returns a string representing the context of the client-side control to be passed on a form submit.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
</tbody>
</table>

Syntax

Web DataWindow client control

```plaintext
string dwcontrol.GetFullContext ()
```

650 PowerBuilder
### GetFullState

**Description**
Retrieves the complete state of a DataWindow or DataStore as a blob.

This method is used primarily in distributed applications.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

---

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

**Return value**
String

**Usage**
Use to host multiple DataWindows.

**Examples**
The following client side script transfers the context and action from one DataWindow to the DataWindow being submitted.

```html
<SCRIPT>
function dw_first_OnSubmit()
{
    dw_first.submitForm.dw_second_context.value = dw_second.GetFullContext();
    dw_first.submitForm.dw_second_action.value = "";
}

function dw_second_OnSubmit()
{
    dw_second.submitForm.dw_first_context.value = dw_first.GetFullContext();
    dw_second.submitForm.dw_first_action.value = "";
}
</SCRIPT>
```

To enable the second DataWindow to create the required fields on the submit form, each of the DataWindows must have two arguments defined in the SelfLinkArgs property:

- dw_first must have dw_second_context and dw_second_action defined
- dw_second must have dw_first_context and dw_first_action defined
GetFullState

Syntax

**PowerBuilder**

```powershell
long dwcontrol.GetFullState ( blob dwasblob )
```

**Web ActiveX**

```powershell
number dwcontrol.GetFullState ( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td>dwasblob</td>
<td>A variable into which the returned DataWindow will be placed.</td>
</tr>
<tr>
<td></td>
<td>For the Web ActiveX, call GetFullStateBlob to get the value instead of</td>
</tr>
<tr>
<td></td>
<td>using the reference variable.</td>
</tr>
</tbody>
</table>

Return value

Returns the number of rows in the DataWindow blob if it succeeds and -1 if an error occurs. GetFullState will return -1 if the DataWindow control or DataStore does not have a DataWindow object associated with it.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

GetFullState retrieves the entire state of a DataWindow or DataStore, including the DataWindow object specification, the data buffers, and the status flags. When you call SetFullState to apply the blob created by GetFullState to another DataWindow, the target DataWindow has enough information to recreate the source DataWindow.

Because the blob created by GetFullState contains the DataWindow object specification, a subsequent call to SetFullState will overwrite the DataWindow object for the target DataWindow control or DataStore. If the target of SetFullState does not have a DataWindow object associated with it, the blob will assign one. In this case, SetFullState has the effect of setting the DataObject property for the target.

When you use GetFullState and SetFullState to synchronize a DataWindow control on a client with a DataStore on a server, you need to make sure that the DataWindow object for the DataStore contains the presentation style you want to display on the client.

Examples

These statements retrieve data into a DataStore and use GetFullState to retrieve the complete state of the DataStore into a blob:

```powershell
// Instance variables:
// datastore ids_datastore
// blob blb_data
long ll_rv

ids_datastore = create datastore
ids_datastore.dataobject = "d_emplist"
```
ids_datastore.SetTransObject (SQLCA)
ids_datastore.Retrieve()
ll_rv = ids_datastore.GetFullState(blb_data)

See also
GetChanges
GetFullStateBlob
GetStateStatus
SetChanges
SetFullState

GetFullStateBlob

Description
Returns the state of a DataWindow or DataStore. You must call GetFullState first to set up the state information. This method is used primarily in distributed applications.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**Web ActiveX**

```c
string dwcontrol.GetFullStateBlob ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control for which you just called GetFullState</td>
</tr>
</tbody>
</table>

Return value

Returns a string whose value is the DataWindow state blob set up by GetFullState.

If `dwcontrol` is null, the method returns null.

Usage

GetFullState and GetFullStateBlob are used in conjunction with SetFullState to synchronize two or more DataWindows or DataStores. For details, see GetFullState on page 651.

Examples

These statements use GetChanges to capture changes to a DataWindow control on a client. If GetChanges succeeds, the client calls a remote object function that applies the changes to a DataStore on the server and updates the database:

```c
blob lblb_changes
long ll_rv

ll_rv = dw_employee.GetChanges(lblb_changes)
```
GetItem

Description
Gets the value of an item for the specified row and column in a Web DataWindow client control. Use one of the datatype-specific methods such as GetItemString for other types of DataWindow control. GetItem returns the value available in the data available to the client. This is equivalent to the primary buffer in other environments.

Applies to
DataWindow type | Method applies to
---|---
Web | Client control

Syntax
**Web DataWindow client control**

```
 returnValue dwcontrol.GetItem (number row, number column )
```

```
 returnValue dwcontrol.GetItem (number row, string column )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row location of the data.</td>
</tr>
<tr>
<td>column</td>
<td>The column location of the data. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—-not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for <em>column</em>. Computed fields do not have numbers.</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Return value
Returns the value in the specified row and column. The datatype of the returned data corresponds to the datatype of the column. Returns null if the column value is null. Returns the empty string ("") if an error occurs.

If any argument value is null, the method returns null.

Usage
Use GetItem to get data that has been accepted by the DataWindow. In a script for the ItemChanged or ItemError event, you can use the newValue argument to find out what the user entered before the data is accepted.

Examples
This statement sets LName to the value for row 3 of the emp_name column in the DataWindow dw_employee:

\[
\text{var LName = dw_employee.GetItem(3, "emp_name");}
\]

See also
SetItem

GetItemDate

Description
Gets data whose type is Date from the specified buffer of a DataWindow control or DataStore object. You can obtain the data that was originally retrieved and stored in the database from the original buffer, as well as the current value in the primary, delete, or filter buffers.

Separate method names for the Web DataWindow server component
Separate method names, GetItemDateByColNum, GetItemDateByColNumEx, and GetItemDateEx, are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

\[
\text{date dwcontrol.GetItemDate ( long row, string column, DWBuffer dwbuffer, boolean originalvalue )}
\]

\[
\text{date dwcontrol.GetItemDate ( long row, integer column, DWBuffer dwbuffer, boolean originalvalue )}
\]
GetItemDate

Web DataWindow server component

string dwcontrol.GetItemDate ( long row, string column)
string dwcontrol.GetItemDateByColNum ( long row, short column )
string dwcontrol.GetItemDateByColNumEx ( long row, short column, string dwbuffer, boolean originalvalue )
string dwcontrol.GetItemDateEx ( long row, string column, string dwbuffer, boolean originalvalue )

Web ActiveX

Date dwcontrol.GetItemDate ( number row, string column, number dwbuffer, boolean originalvalue )
Date dwcontrol.GetItemDate ( number row, number column, number dwbuffer, boolean originalvalue )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row location of the data.</td>
</tr>
<tr>
<td>column</td>
<td>The column location of the data. The datatype of the column must be date. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for column. Computed fields do not have numbers.</td>
</tr>
<tr>
<td>dwbuffer</td>
<td>(optional) A value identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>originalvalue</td>
<td>(optional) A boolean indicating whether you want the original or current values for row and column:</td>
</tr>
<tr>
<td></td>
<td>• True – Returns the original values (the values initially retrieved from the database).</td>
</tr>
<tr>
<td></td>
<td>• False – (Default) Returns the current values.</td>
</tr>
<tr>
<td></td>
<td>If you specify dwbuffer, you must also specify originalvalue.</td>
</tr>
</tbody>
</table>

Return value

Returns the date value in the specified row and column. Returns null if the column value is null or if there is no DataWindow object assigned to the DataWindow control or DataStore. Returns 1900-01-01 if any other error occurs.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.
Usage

Use GetItemDate when you want to get information from the DataWindow’s buffers. To find out what the user entered in the current column before that data is accepted, use GetText. In the ItemChanged or ItemError events, use the data argument.

To access a row in the original buffer, specify the buffer that the row currently occupies (primary, delete, or filter) and the number of the row in that buffer. When you specify true for originalvalue, the method gets the original data for that row from the original buffer.

An execution error occurs when the datatype of the DataWindow column does not match the datatype of the method; in this case, date.

Datatypes of columns and computed fields

There is a difference in datatypes between columns and computed columns retrieved from the database and computed fields defined in the DataWindow painter. Computed columns from the database can have a datatype of date, but a date computed field always has a datatype of DateTime, not date. In PowerBuilder, use the GetItemDateTime method instead.

Web ActiveX only: columns involving dates

Use GetItemDate for all columns of type date, DateTime, and time.

PowerBuilder only: using GetItemDate in a String function

When you call GetItemDate as an argument for the String function and do not specify a display format, the value is formatted as a DateTime value. This statement returns a string like "2/26/96 00:00:00":

```powerbuilder
String(dw_1.GetItemDate(1, "start_date"))
```

To get a simple date string, you can specify a display format:

```powerbuilder
String(dw_1.GetItemDate(1, "start_date"), "m/d/yy")
```

or you can assign the date to a date variable before calling the String function:

```powerbuilder
date ld_date
string ls_date
ld_date = dw_1.GetItemDate(1, "start_date")
ls_date = String(ld_date)
```
GetItemDateTime

Examples

These statements set hiredate to the current Date data in the third row of the primary buffer in the column named first_day of dw_employee:

```powerbuilder
Date hiredate
hiredate = dw_employee.GetItemDate(3, "first_day")
```

These statements set hiredate to the current Date data in the third row of the filter buffer in the column named first_day of dw_employee:

```powerbuilder
Date hiredate
hiredate = dw_employee.GetItemDate(3, & "first_day", Filter!, false)
```

These statements set hiredate to original Date data in the third row of the primary buffer in the column named hdate of dw_employee:

```powerbuilder
Date hiredate
hiredate = dw_employee.GetItemDate(3, & "hdate", Primary!, true)
```

GetItemDateTime

Description

Gets data whose type is DateTime from the specified buffer of a DataWindow control or DataStore object. You can obtain the data that was originally retrieved and stored in the database from the original buffer, as well as the current value in the primary, delete, or filter buffers.

Separate method names for the Web DataWindow server component

Separate method names, GetItemDateTimeEx, GetItemDateTimeByColNum, and GetItemDateTimeByColNumEx, are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.
CHAPTER 9  Methods for the DataWindow Control

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
DateTime dwcontrol.GetItemDateTime ( long row, string column )
```

```
DateTime dwcontrol.GetItemDateTime ( long row, integer column )
```

**Web DataWindow server component**

```
string dwcontrol.GetItemDateTime ( long row, string column)
```

```
string dwcontrol.GetItemDateTimeByColNum ( long row, short column )
```

```
string dwcontrol.GetItemDateTimeByColNumEx ( long row, short column, string dwbuffer, boolean originalvalue )
```

```
string dwcontrol.GetItemDateTimeEx ( long row, string column, string dwbuffer, boolean originalvalue )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>dwcontrol</strong></td>
<td>A reference to the DataWindow control, DataStore, or child DataWindow in which you want to obtain the DateTime data contained in a specific row and column.</td>
</tr>
<tr>
<td><strong>row</strong></td>
<td>A value identifying the row location of the data.</td>
</tr>
<tr>
<td><strong>column</strong></td>
<td>The column location of the data. The datatype of the column must be DateTime. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for column. Computed fields do not have numbers.</td>
</tr>
<tr>
<td><strong>dwbuffer</strong> (optional)</td>
<td>A value identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>
| **originalvalue** (optional) | A boolean indicating whether you want the original or current values for row and column:  
• True – Returns the original values, that is, the values initially retrieved from the database.  
• False – (Default) Returns the current values.  
If you specific dwbuffer, you must also specify originalvalue. |
**GetItemDateTime**

**Return value**

Returns the DateTime or Timestamp value in the specified row and column. Returns null if the column value is null or if there is no DataWindow object assigned to the DataWindow control or DataStore. Returns 1900-01-01 00:00:00.000000 if any other error occurs.

If any argument value is null, in PowerBuilder the method returns null.

**Usage**

Use GetItemDateTime when you want to get information from the DataWindow’s buffers. To find out what the user entered in the current column before that data is accepted, use GetText. In the ItemChanged or ItemError events, use the data argument.

To access a row in the original buffer, specify the buffer that the row currently occupies (primary, delete, or filter) and the number of the row in that buffer. When you specify true for originalvalue, the method gets the original data for that row from the original buffer.

**Datatype mismatch**

An execution error occurs when the datatype of the DataWindow column does not match the datatype of the method—in this case, DateTime.

Computed fields displaying date or time values have a datatype of DateTime, not date or time. Always use GetItemDateTime to get their value, not GetItemDate or GetItemTime.

**Examples**

These statements set as_of to the current DateTime data in the primary buffer for row 3 of the column named start_dt in the DataWindow dw_emp:

```powerbuilder
datetime as_of
as_of = dw_emp.GetItemDateTime(3, "start_dt")
```

These statements set as_of to the current DateTime data in the delete buffer for row 3 of the end_dt column of dw_emp:

```powerbuilder
datetime as_of
as_of = dw_emp.GetItemDateTime(3, "end_dt", &Delete!, false)
```

These statements set AsOf to the original DateTime data in the primary buffer for row 3 of the end_dt column of dw_emp:

```powerbuilder
datetime as_of
as_of = dw_emp.GetItemDateTime(3, "end_dt", &Primary!, true)
```

GetItemDecimal

Description
Gets data whose type is decimal from the specified buffer of a DataWindow control or DataStore object. You can obtain the data that was originally retrieved and stored in the database from the original buffer, as well as the current value in the primary, delete, or filter buffers.

Applies to
DataWindow type | Method applies to
--- | ---
PowerBuilder | DataWindow control, DataWindowChild object, DataStore object

Syntax

**PowerBuilder**

```powerbuilder
decimal dwcontrol.GetItemDecimal ( long row, integer column
{, DWBuffer dwbuffer, boolean originalvalue } )
decimal dwcontrol.GetItemDecimal ( long row, string column
{, DWBuffer dwbuffer, boolean originalvalue } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td><code>row</code></td>
<td>A value identifying the row location of the decimal data.</td>
</tr>
<tr>
<td><code>column</code></td>
<td>The column location of the data. The datatype of the column must be one of type decimal. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for column. Computed fields do not have numbers.</td>
</tr>
<tr>
<td><code>dwbuffer</code></td>
<td>A value of the dwBuffer enumerated datatype identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>(optional)</td>
<td></td>
</tr>
</tbody>
</table>
GetItemDecimal

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>originalvalue</td>
<td>A boolean indicating whether you want the original or current values for row and column:</td>
</tr>
<tr>
<td></td>
<td>• True – Returns the original values, that is, the values initially retrieved from the database.</td>
</tr>
<tr>
<td></td>
<td>• False – (Default) Returns the current values.</td>
</tr>
<tr>
<td></td>
<td>If you specify dwbuffer, you must also specify originalvalue.</td>
</tr>
</tbody>
</table>

**Usage**

Use GetItemDecimal when you want to get information from the DataWindow’s buffers. To find out what the user entered in the current column before that data is accepted, use GetText. In the ItemChanged or ItemError events, use the data argument.

To access a row in the original buffer, specify the buffer that the row currently occupies (primary, delete, or filter) and the number of the row in that buffer. When you specify true for originalvalue, the method gets the original data for that row from the original buffer.

**Handling errors**  The return value is a valid value from the database unless the SystemError event is triggered. When the value cannot be converted because the column’s datatype does not match the method’s datatype, an execution error occurs, which triggers the SystemError event. The default error processing halts the application.

If you write a script for the SystemError event, it should also halt the application. Therefore, the error return value is seldom used.

**Examples**

These statements set salary_amt to the current decimal data in the primary buffer for row 4 of the column named emp_salary of dw_employee:

```plaintext
decimal salary_amt
salary_amt = &
    dw_employee.GetItemDecimal(4, "emp_salary")
```

These statements set salary_amt to the current decimal data in the filter buffer for row 4 of the column named emp_salary of dw_employee:

```plaintext
decimal salary_amt
salary_amt = dw_employee.GetItemDecimal(4, &
    "emp_salary", Filter!, false)
```
These statements set salary_amt to the original decimal data in the primary buffer for row 4 of the column named emp_salary of dw_employee:

```powerbuilder
decimal salary_amt
salary_amt = dw_employee.GetItemDecimal(4, & "emp_salary", Primary!, true)
```

### GetItemFormattedString

**Description**

Gets and formats data whose type is String from the specified buffer of a DataWindow control or DataStore object.

**Separate method names for the Web DataWindow server component**

Separate method names, `GetItemFormattedStringByColNum`, `GetItemFormattedStringByColNumEx`, and `GetItemFormattedStringEx`, are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
string dwcontrol.GetItemFormattedString ( long row, integer column 
{, DWBuffer dwbuffer, boolean originalvalue } )
string dwcontrol.GetItemFormattedString ( long row, string column 
{, DWBuffer dwbuffer, boolean originalvalue } )
```
GetItemFormattedString

Web DataWindow server component

```
string dwcontrol.GetItemFormattedString ( long row, string column )
string dwcontrol.GetItemFormattedStringByColNum ( long row, short column )
string dwcontrol.GetItemFormattedStringByColNumEx ( long row, short column, string dwbuffer, boolean originalvalue )
string dwcontrol.GetItemFormattedStringEx ( long row, string column, string dwbuffer, boolean originalvalue )
```

Web ActiveX

```
string dwcontrol.GetItemFormattedString (number row, number column, number dwbuffer, boolean originalvalue )
string dwcontrol.GetItemFormattedString (number row, string column, number dwbuffer, boolean originalvalue )
```

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row location of the string data.</td>
</tr>
<tr>
<td>column</td>
<td>The column identifying the column. The datatype of the column must be String. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for column. Computed fields do not have numbers.</td>
</tr>
<tr>
<td>dwbuffer</td>
<td>(optional) A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) or a string (Web DataWindow) identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>originalvalue</td>
<td>(optional) A boolean indicating whether you want the original or current values for row and column:</td>
</tr>
<tr>
<td></td>
<td>• True – Returns the original values (the values initially retrieved from the database).</td>
</tr>
<tr>
<td></td>
<td>• False – (Default) Returns the current values.</td>
</tr>
<tr>
<td></td>
<td>If you specify dwbuffer, you must also specify originalvalue.</td>
</tr>
</tbody>
</table>

Usage

Use GetItemFormattedString in place of GetItemString when you want to return the value from a column in its current display format. This is especially useful if the column in question is not a computed column.
CHAPTER 9 Methods for the DataWindow Control

Examples

These statements set LName to the current string in the primary buffer for row 3 of in the column named emp_name in the DataWindow dw_employee. The retrieved value is formatted with the display format of the column:

```powershell
String LName
LName = dw_employee.GetItemFormattedString(3, "emp_name")
```

GetItemString
GetItemUnformattedString

GetItemNumber

Description

Gets numeric data from the specified buffer of a DataWindow control or DataStore object. You can obtain the data that was originally retrieved and stored in the database from the original buffer, as well as the current value in the primary, delete, or filter buffers.

Separate method names for the Web DataWindow server component

Separate method names, GetItemNumberEx, GetItemNumberByColNumEx, and GetItemNumberByColNum, are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
numeric dwcontrol.GetItemNumber ( long row, string column
   ( DWBuffer dwbuffer, boolean originalvalue ) )
numeric dwcontrol.GetItemNumber ( long row, integer column
   ( DWBuffer dwbuffer, boolean originalvalue ) )
```

**Web DataWindow server component**

```powershell
double dwcontrol.GetItemNumber ( long row, string column )
double dwcontrol.GetItemNumberByColNum ( long row, short column )
double dwcontrol.GetItemNumberEx ( long row, string column, string dwbuffer, boolean originalvalue )
double dwcontrol.GetItemNumberByColNumEx ( long row, short column, string dwbuffer, boolean originalvalue )
```
GetItemNumber

Web ActiveX

number dwcontrol.GetItemNumber( number row, string column, number dwbuffer, boolean originalvalue )

number dwcontrol.GetItemNumber( number row, number column, number dwbuffer, boolean originalvalue )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row location of the numeric data.</td>
</tr>
<tr>
<td>column</td>
<td>The column location of the numeric data. The datatype of the column must be one of a numeric datatype. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for column. Computed fields do not have numbers.</td>
</tr>
<tr>
<td>dwbuffer</td>
<td>(optional) A value identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>originalvalue</td>
<td>(optional) A boolean indicating whether you want the original or current values for row and column:</td>
</tr>
<tr>
<td></td>
<td>• True – Return the original values (the values initially retrieved from the database).</td>
</tr>
<tr>
<td></td>
<td>• False – (Default) Return the current values.</td>
</tr>
<tr>
<td></td>
<td>If you specify dwbuffer, you must also specify originalvalue.</td>
</tr>
</tbody>
</table>

Return value

Returns the numeric value in the specified row and column (decimal, double, integer, long, or real). Returns null if the column value is null or if there is no DataWindow object assigned to the DataWindow control or DataStore. Triggers the SystemError event and returns -1 if any other error occurs (see “Handling errors” on page 667).

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Use GetItemNumber to get information from the DataWindow’s buffers. To find out what the user entered in the current column before that data is accepted, use GetText. In the ItemChanged or ItemError events, use the data argument.
To access a row in the original buffer, specify the buffer that the row currently occupies (primary, delete, or filter) and the number of the row in that buffer. When you specify true for originalvalue, the method gets the original data for that row from the original buffer.

Handling errors  The return value is a valid value from the database unless the SystemError event is triggered. When the value cannot be converted because the column’s datatype does not match the method’s datatype, an execution error occurs, which triggers the SystemError event. The default error processing halts the application. If you write a script for the SystemError event, it should also halt the application. Therefore, the error return value is seldom used.

Examples  These statements set EmpNbr to the current numeric data in the primary buffer for row 4 of the column named emp_nbr in dw_employee:

```
integer EmpNbr
EmpNbr = dw_employee.GetItemNumber(4, "emp_nbr")
```

These statements set EmpNbr to the current numeric data in the filter buffer for row 4 of the column named salary of dw_employee:

```
integer EmpNbr
EmpNbr = dw_employee.GetItemNumber(4, & "salary", Filter!, false)
```

These statements set EmpNbr to the original numeric data in the primary buffer for row 4 of the column named salary of dw_Employee:

```
integer EmpNbr
EmpNbr = dw_Employee.GetItemNumber(4, & "salary", Primary!, true)
```

GetItemStatus

Description
Reports the modification status of a row or a column within a row. The modification status determines the type of SQL statement the Update method will generate for the row or column.

GetItemStatusByColNum
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

   DWItemStatus dwcontrol.GetItemStatus ( long row, integer column, DWBuffer dwbuffer )
   DWItemStatus dwcontrol.GetItemStatus ( long row, string column, DWBuffer dwbuffer )

Web DataWindow client control

   number dwcontrol.GetItemStatus ( number row, number column )
   number dwcontrol.GetItemStatus ( number row, string column )

Web DataWindow server component

   string dwcontrol.GetItemStatus ( long row, string column, string dwbuffer )
   string dwcontrol.GetItemStatusByColNum ( long row, short column, string dwbuffer )

Web ActiveX

   number dwcontrol.GetItemStatus ( number row, number column, number dwbuffer )
   number dwcontrol.GetItemStatus ( number row, string column, number dwbuffer )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row for which you want the status.</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Return value

A value of the dwItemStatus enumerated datatype (PowerBuilder) or an integer (Web ActiveX and server-side Web DataWindow controls) or a string (Web DataWindow client control). The return value identifies the status of the item at row, column of dwcontrol in dwbuffer. For a list of status values, see DWItemStatus on page 479.

If column is 0, GetItemStatus returns the status of row. If there is no DataWindow object assigned to the DataWindow control or DataStore, GetItemStatus returns null.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Use GetItemStatus to understand what SQL statements will be generated for new and changed information when you update the database.

For rows in the primary and filter buffers, Update generates an INSERT statement for rows with NewModified! status. It generates an UPDATE statement for rows with DataModified! status and references the columns that have been affected.

For rows in the delete buffer, Update does not generate a DELETE statement for rows whose status was New! or NewModified! before being moved to the delete buffer.

Examples

These statements store in the variable l_status the status of the column named emp_status in row 5 in the filter buffer of dw_1:

```powerbuilder
  dwItemStatus l_status
  l_status = dw_1.GetItemStatus(5, "emp_status", &Filter!)
```

These statements store in the variable l_status the status of the column named Salary in the current row in the primary buffer of dw_emp:

```powerbuilder
dwItemStatus l_status
```
**GetItemString**

l_status = dw_emp.GetItemStatus( &
   dw_emp.GetRow(), "Salary", Primary!)

See also
SetItemStatus

**GetItemString**

**Description**

Gets data whose type is String from the specified buffer of a DataWindow control or DataStore object. You can obtain the data that was originally retrieved and stored in the database from the original buffer, as well as the current value in the primary, delete, or filter buffers.

Separate method names for the Web DataWindow server component
Separate method names, GetItemStringEx, GetItemStringByColNumEx, and GetItemStringByColNum, are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powershell
string dwcontrol.GetItemString ( long row, integer column
   {, DWBuffer dwbuffer, boolean originalvalue } )
string dwcontrol.GetItemString ( long row, string column
   {, DWBuffer dwbuffer, boolean originalvalue } )
```

**Web DataWindow server component**

```powershell
string dwcontrol.GetItemString ( long row, string column )
string dwcontrol.GetItemStringByColNum ( long row, short column )
string dwcontrol.GetItemStringByColNumEx ( long row, short column,
   string dwbuffer, boolean originalvalue )
string dwcontrol.GetItemStringEx ( long row, string column,
   string dwbuffer, boolean originalvalue )
```
Web ActiveX

\[
\text{string } \text{dwcontrol.GetItemString} (\text{number row, number column, number dwbuffer, boolean originalvalue})
\]

\[
\text{string } \text{dwcontrol.GetItemString} (\text{number row, string column, number dwbuffer, boolean originalvalue})
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{dwcontrol}</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>\text{row}</td>
<td>A value identifying the row location of the string data.</td>
</tr>
<tr>
<td>\text{column}</td>
<td>The column location of the data. The datatype of the column must be String.</td>
</tr>
<tr>
<td>\text{dwbuffer}</td>
<td>(optional) A value of the dwBuffer enumerated datatype (PowerBuilder) or an</td>
</tr>
<tr>
<td></td>
<td>integer (Web ActiveX) or a string (Web DataWindow) identifying the DataWindow</td>
</tr>
<tr>
<td></td>
<td>buffer from which you want to get the data. For a list of valid values, see</td>
</tr>
<tr>
<td></td>
<td>DWBuffer on page 478.</td>
</tr>
<tr>
<td>\text{originalvalue}</td>
<td>(optional) A boolean indicating whether you want the original or current</td>
</tr>
<tr>
<td></td>
<td>values for \text{row} and \text{column}:</td>
</tr>
<tr>
<td></td>
<td>\text{True} – Returns the original values (the values initially retrieved</td>
</tr>
<tr>
<td></td>
<td>from the database).</td>
</tr>
<tr>
<td></td>
<td>\text{False} – (Default) Returns the current values.</td>
</tr>
<tr>
<td></td>
<td>If you specify \text{dwbuffer}, you must also specify \text{originalvalue}.</td>
</tr>
</tbody>
</table>

Return value

Returns the string value in the specified row and column. Returns the empty string (""") if there is no DataWindow object assigned to the DataWindow control or DataStore or if any other error occurs.

If any argument value is null, in PowerBuilder the method returns null.

Usage

Use \text{.GetItemString} to get information from the DataWindow’s buffers. To find out what the user entered in the current column before that data is accepted, use \text{GetText}. In the ItemChanged or ItemError events, use the data argument.

To access a row in the original buffer, specify the buffer that the row currently occupies (primary, delete, or filter) and the number of the row in that buffer. When you specify \text{true} for \text{originalvalue}, the method gets the original data for that row from the original buffer.
**GetItemString**

GetItemString returns a formatted value in the case of a computed column, and an unformatted value in the case of a noncomputed column. For PowerBuilder DataWindows, you can use the GetItemFormattedString method to return a formatted value, or the GetItemUnformattedString method to return an unformatted value, for any type of column.

**Mismatched datatypes**

An execution error occurs when the datatype of the DataWindow column does not match the datatype of the method—in this case, String.

**Examples**

These statements set LName to the current string in the primary buffer for row 3 of the column named emp_name in the DataWindow dw_employee:

```powershell
String LName
LName = dw_employee.GetItemString(3, "emp_name")
```

These statements set LName to the current string in the delete buffer for row 3 of the column named emp_name of dw_employee:

```powershell
String LName
LName = dw_employee.GetItemString(3, &
    "emp_name", Delete!, false)
```

The following statements set LName to the original string in the delete buffer for row 3 of the column named emp_name of dw_employee:

```powershell
String LName
LName = dw_employee.GetItemString(3, &
    "emp_name", Delete!, true)
```

**GetItemTime**

**Description**

Gets data whose type is Time from the specified buffer of a DataWindow control or DataStore object. You can obtain the data that was originally retrieved and stored in the database from the original buffer, as well as the current value in the primary, delete, or filter buffers.

**Separate method names for the Web DataWindow server component**

Separate method names, GetItemTimeByColNum, GetItemTimeByColNumEx, and GetItemTimeEx are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powershell
time dwcontrol.GetItemTime ( long row, string column {, DWBuffer dwbuffer, boolean originalvalue } )
time dwcontrol.GetItemTime ( long row, integer column {, DWBuffer dwbuffer, boolean originalvalue } )
```

**Web DataWindow server component**

```powershell
string dwcontrol.GetItemTime ( long row, string column )
string dwcontrol.GetItemTimeByColNum ( long row, short column )
string dwcontrol.GetItemTimeByColNumEx ( long row, short column, string dwbuffer, boolean originalvalue )
string dwcontrol.GetItemTimeEx ( long row, string column, string dwbuffer, boolean originalvalue )
```

**Argument** | **Description**
---|---
*dwcontrol* | A reference to a DataWindow control, DataStore, or child DataWindow.
*row* | A value identifying the row location of the data.
*column* | The column location of the data. The datatype of the column must be time. *Column* can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view.
To get the contents of a computed field, specify the name of the computed field for *column*. Computed fields do not have numbers.
GetItemTime

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwbuffer (optional)</td>
<td>A value of the dwBuffer enumerated datatype (PowerBuilder) or a string (Web DataWindow) identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>
| originalvalue (optional) | A boolean indicating whether you want the original or current values for row and column:  
  - True – Return the original values (the values initially retrieved from the database).  
  - False – (Default) Return the current values.  
  If you specify dwbuffer, you must also specify originalvalue. |

Return value

Returns the time value in the specified row and column. Returns null if the column value is null or if there is no DataWindow object assigned to the DataWindow control or DataStore. Returns 00:00:00.000000 if an error occurs.

If any argument value is null, in PowerBuilder the method returns null.

Usage

Use GetItemTime to get information from the DataWindow’s buffers. To find out what the user entered in the current column before that data is accepted, use GetText. In the ItemChanged or ItemError events, use the data argument.

To access a row in the original buffer, specify the buffer that the row currently occupies (primary, delete, or filter) and the number of the row in that buffer. When you specify true for originalvalue, the method gets the original data for that row from the original buffer.

Datatypes of columns and computed fields

An execution error occurs when the datatype of the DataWindow column does not match the datatype of the method—in this case, time.

There is a difference in datatypes between computed columns retrieved from the database and computed fields defined in the DataWindow painter. Computed columns from the database can have a datatype of time, but a time computed field always has a datatype of DateTime, not time. Use the GetItemDateTime method instead.
PowerBuilder only: using GetItemTime in a String function

When you call GetItemTime as an argument for the String function and do not specify a display format, the value is formatted as a DateTime value. This statement returns a string like "2/26/06 00:00:00":

```plaintext
String(dw_1.GetItemTime(1, "start_date"))
```

To get a simple time string, you can specify a display format for the String function or you can assign the value to a time variable before calling the String function (see GetItemDate for examples).

### Examples

These statements set Start to the current Time data in the primary buffer for row 3 of the column named title in dw_employee:

```plaintext
Time Start
Start = dw_employee.GetItemTime(3, "title")
```

These statements set Start to the current Time data in the filter buffer for row 3 of the column named start_time of dw_employee:

```plaintext
Time Start
Start = dw_employee.GetItemTime(3, &"start_time", Filter!, false)
```

These statements set Start to the original Time data in the primary buffer for row 3 of the column named start_time of dw_employee:

```plaintext
Time Start
Start = dw_employee.GetItemTime(3, &"start_time", Primary!, true)
```

**GetItemUnformattedString**

**Description**

Gets raw (unformatted) data whose type is String from the specified buffer of a DataWindow control or DataStore object.

**Separate methods for Web DataWindow Server component**

Separate method names, `GetItemUnformattedStringByColNum`, `GetItemUnformattedStringEx`, and `GetItemUnformattedStringByColNumEx` are provided as alternative syntaxes for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
string dwcontrol.GetItemUnformattedString ( long row, integer column {, DWBuffer dwbuffer, boolean originalvalue } )
string dwcontrol.GetItemUnformattedStringEx ( long row, string column {, DWBuffer dwbuffer, boolean originalvalue } )
```

**Web DataWindow server component**

```powerbuilder
string dwcontrol.GetItemUnformattedString ( long row, string column )
string dwcontrol.GetItemUnformattedStringByColNum ( long row, short column )
string dwcontrol.GetItemUnformattedStringByColNumEx ( long row, short column, string dwbuffer, boolean originalvalue )
string dwcontrol.GetItemUnformattedStringEx ( long row, string column, string dwbuffer, boolean originalvalue )
```

**Web ActiveX**

```powerbuilder
string dwcontrol.GetItemUnformattedString ( number row, number column, number dwbuffer, boolean originalvalue )
string dwcontrol.GetItemUnformattedStringEx ( number row, string column, number dwbuffer, boolean originalvalue )
```

**Argument** | **Description**
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td><code>row</code></td>
<td>A value identifying the row location of the string data.</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Usage
Use GetItemUnformattedString in place of GetItemString when you want to return the value from a column without its display format. This is especially useful if the column in question is a computed column.

Examples
These statements set LName to the current string in the primary buffer for row 3 of in the column named emp_name in the DataWindow dw_employee. The retrieved value is unformatted:

```plaintext
String LName
LName = dw_employee.GetItemUnformattedString(3, "emp_name")
```

See also
GetItemFormattedString
GetItemString

GetLastError

Description
Returns the error code of the last database error that occurred in the Web DataWindow server component.

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>The column location of the data. The datatype of the column must be String. Column can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view. To get the contents of a computed field, specify the name of the computed field for column. Computed fields do not have numbers.</td>
</tr>
<tr>
<td>dwbuffer (optional)</td>
<td>A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) or a string (Web DataWindow) identifying the DataWindow buffer from which you want to get the data. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>
| originalvalue (optional) | A boolean indicating whether you want the original or current values for row and column:  
  - True – Returns the original values (the values initially retrieved from the database).  
  - False – (Default) Returns the current values.  
  If you specify dwbuffer, you must also specify originalvalue. |
GetLastErrorString

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

Web DataWindow server component

long dwcontrol.GetLastError ( )

Argument | Description
---------|-----------------

dwcontrol | A reference to the DataWindow server component

Return value

Returns a numeric error code for the last database error that occurred.

If dwcontrol is null, the method returns null.

Usage

Call GetLastError and GetLastErrorString to get information about database errors that caused SetAction, Update, Retrieve, and RetrieveEx to return –1.

Examples

This code in a page server script calls Retrieve for the Web DataWindow server component called dwComponent and gets information about the database error if Retrieve fails:

```java
retVal = dwComponent.Retrieve( );
if (retVal < 0) {
    Response.Write("Retrieval error: 
    + dwComponent.GetLastError( )
    + 
    + dwComponent.GetLastErrorString( )
    + 
    + "<BR>" );
}
```

See also

GetLastErrorString
Retrieve
Update

GetLastErrorString

Description

Returns the text of the error message for the last database error that occurred in the Web DataWindow server component.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>
### Syntax

Web DataWindow server component

```
string dwcontrol.GetLastErrorString()  
```

**Argument** | **Description**
---|---
`dwcontrol` | A reference to the DataWindow server component

**Return value**

Returns a string containing an error message for the last database error that occurred.

If `dwcontrol` is `null`, the method returns `null`.

**Usage**

Call `GetLastError` and `GetLastErrorString` to get information about database errors that caused `SetAction`, `Update`, `Retrieve`, and `RetrieveEx` to return `-1`.

**Examples**

This code in a page server script calls `Retrieve` for the Web DataWindow server component called `dwComponent` and gets information about the database error if `Retrieve` fails:

```csharp
retVal = dwComponent.Retrieve();
if (retVal < 0) {
    Response.Write("Retrieval error: " + dwComponent.GetLastError() + "<BR>
    + dwComponent.GetLastErrorString();
}
```

**See also**

- `GetLastError`
- `Retrieve`
- `Update`

---

### GetMessageText

**Description**

Obtains the message text generated by a crosstab DataWindow object in a DataWindow control. Only crosstab DataWindows generate messages.

**Obsolete method**

GetMessageText is obsolete and will be discontinued in a future release. You should replace all use of `GetMessageText` as soon as possible. The message text is available as an argument in a user event defined for `pbm_dwnmessagetext` in a DataWindow control.
GetNextModified

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
string dwcontrol.GetMessageText ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control for which you want the message text</td>
</tr>
</tbody>
</table>

Return value

Returns the text of the message generated by `dwcontrol`. If there is no text or an error occurs, `GetMessageText` returns the empty string ("").

If `dwcontrol` is null, the method returns null.

Usage

To use `GetMessageText`, you must first define a user-defined event for the event ID `pbm_dwnmessagetext`; then you call this method in the script for that event.

Typical messages are **Retrieving data** and **Building crosstab**.

Examples

This statement is part of a script for a user-defined event with the ID `pbm_dwmessagetext`. The style of the DataWindow object in the DataWindow control is crosstab. The statement sets the MicroHelp of the MDI frame window `w_crosstab`:

```powerbuilder
w_crosstab.SetMicroHelp(This.GetMessageText())
```

---

GetNextModified

Description

Reports the next row that has been modified in the specified buffer.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
long dwcontrol.GetNextModified (long row, DWindow dwbuffer )
```
Web DataWindow client control

```
number dwcontrol.GetNextModified (number row, number column)
```

Web ActiveX

```
number dwcontrol.GetNextModified (number row, number dwbuffer)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A name of the DataWindow control, DataStore, or child DataWindow in which you want to locate the modified row.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row location after which you want to locate the modified row. To search from the beginning, specify 0.</td>
</tr>
<tr>
<td>dwbuffer</td>
<td>A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the DataWindow buffer in which you want to locate the modified row. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>

Return value

Returns the number of the first row that was modified after `row` in `dwbuffer` in `dwcontrol`. Returns 0 if there are no modified rows after the specified row.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

PowerBuilder stores the update status of rows and columns in the DataWindow. The status settings indicate whether a row or column is new or has been modified. `GetNextModified` reports rows with the status NewModified! and DataModified!.

For more information on the status of rows and columns, see `GetItemStatus` and `SetItemStatus`.

Using `GetNextModified` on the delete buffer will return rows that have been modified and then deleted. The `DeletedCount` method will report the total number of deleted rows.

`GetNextModified` begins searching in the row after the value you specify in `row`. This is different from the behavior of `Find`, `FindGroupChange`, and `FindRequired`, which begin searching in the row you specify.

Web DataWindow `GetNextModified` finds changed rows only on the current page. The result set for the DataWindow can include rows that are on the server but not displayed in the browser. `GetNextModified` cannot find changed rows that are on the server but not on the client’s current page.
GetObjectAtPointer

**Total number of modified rows**
You can use the `ModifiedCount` method to find out the total number of modified rows in the primary and filter buffers.

**Examples**
These statements count the number of rows that were modified in the primary buffer for `dw_status` and then display a message reporting the number modified:

```powershell
integer rc
long NbrRows, ll_row = 0, count = 0

dw_status.AcceptText()
NbrRows = dw_status.RowCount()
DO WHILE ll_row <= NbrRows
    ll_row = dw_status.GetNextModified(ll_row, Primary!)
    IF ll_row > 0 THEN
        count = count + 1
    ELSE
        ll_row = NbrRows + 1
    END IF
LOOP
MessageBox("Modified Count", &
    String(count) &
    + " rows were modified.")
```

See also
- DeletedCount
- FindRequired
- GetNextModified
- ModifiedCount
- SetItemStatus

**GetObjectAtPointer**

**Description**
Reports the control within the DataWindow object and row number under the pointer. Controls include columns, labels, and other graphic controls, such as lines and pictures.
Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```java
string dwcontrol.GetObjectAtPointer()
```

**Web ActiveX**

```java
string dwcontrol.GetObjectAtPointer()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

Return value

Returns the string whose value is the name of the control under the pointer, followed by a tab character and the row number. Returns the empty string ("") if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

Usage

If the object doesn’t have a name, neither a name nor a row is reported. Since PowerBuilder 7, the painter gives names to all controls. In earlier versions, only columns and column labels got default names in the DataWindow painter and you could name other controls yourself.

You can parse the return value by searching for the tab character (ASCII 09). In PowerBuilder, search for ~t. For an example that parses a string that includes a tab, see GetValue.

For information on the rows associated with bands and therefore with controls in those bands, see GetBandAtPointer.

Examples

These statements obtain the name of the control under the pointer in the DataWindow `dw_emp`:

```java
String dwobjectname

dwobjectname = dw_emp.GetObjectAtPointer()
```

Some possible return values are:

<table>
<thead>
<tr>
<th>Return value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>salary~t23</code></td>
<td>The control named salary in row 23.</td>
</tr>
<tr>
<td><code>salary_h~t15</code></td>
<td>The control named salary_h, which is in the header. Row 15 is the first visible row below the header.</td>
</tr>
</tbody>
</table>

See also

GetBandAtPointer
GetParent

Description
Obtains the parent of the specified object.

Applies to
DataWindow type | Method applies to
--- | ---
PowerBuilder | DataWindow control, DataWindowChild object, DataStore object

Syntax

**PowerBuilder**

```powerbuilder
PowerObject objectname.GetParent()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>objectname</code></td>
<td>A control in a window or user object or an item on a menu for which you want the parent object</td>
</tr>
</tbody>
</table>

Return value
Returns a reference to the parent of `objectname`.

Usage
Inherited from PowerObject. For information, see GetParent in the *PowerScript Reference*.

GetRichTextAlign

Description
Gets the current alignment setting for editing columns with the RichText edit style.

Applies to
DataWindow control

Syntax

```powerbuilder
Integer dwcontrol.GetRichTextAlign(REF alignment align)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td><code>align</code></td>
<td>Current alignment setting of the selected text</td>
</tr>
</tbody>
</table>

Return value
Returns an integer to indicate whether the column that you selected has the RichText edit style and whether the content has one or more alignment types applied.

- `0` Success
- `-1` No RichText column is being edited
- `-2` The selected text is a mix of alignment types

Usage
You can call this method from a button in a custom toolbar that you use to obtain current font settings for columns with the RichText edit style.
Examples
This example obtains the current alignment setting to be used for editing columns with the RichText edit style:

```plaintext
Integer li_integer
Alignment l_align
li_integer = dw_1.GetRichTextAlign(l_align)
```

SetRichTextAlign

---

GetRichTextColor

Description
Gets the current color setting for editing columns with the RichText edit style.

Applies to
DataWindow control

Syntax
```plaintext
Integer dwcontrol.GetRichTextColor ( REF long color )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td>color</td>
<td>A long used to define the color</td>
</tr>
</tbody>
</table>

Return value
Returns an integer to indicate whether the column that you selected has the RichText edit style and whether the content has one or more colors applied.

- 0  Success
- -1 No RichText column is being edited
- -2 The selected text is a mix of colors

Usage
If the color for columns with the RichText edit style is white, background transparency and gradient and text transparency will not work properly.

You can call this method from a button in a custom toolbar that you use to obtain current font settings for columns with the RichText edit style.

Examples
This example obtains the current color setting of the font to be used for editing columns with a RichText edit style:

```plaintext
Integer li_integer
Long l_long
li_integer = dw_1.GetRichTextColor(l_long)
```
GetRichTextFaceName

Description
Gets the current typeface setting for editing columns with the RichText edit style.

Applies to
DataWindow control

Syntax
Integer dwcontrol.GetRichTextFaceName ( REF string typeface )

Argument | Description
------ | -------
dwcontrol | A reference to the DataWindow control
typeface | A string used to define the type

Return value
Returns an integer to indicate whether the column that you selected has the RichText edit style and whether the content has one or more fonts applied.

0 Success
-1 No RichText column is being edited
-2 The selected text is a mix of fonts

Usage
You can call this method from a button in a custom toolbar that you use to obtain current font settings for columns with the RichText edit style.

Examples
This example obtains the typeface of the font to be used for editing columns with a RichText edit style:

```pascal
Integer li_integer
String ls_string
li_integer = dw_1.GetRichTextFaceName(ls_string)
```

If Tahoma font is selected when the above script is called, ls_string is Tahoma and the method returns 0. If a mix of fonts is selected, ls_string is blank and the method returns −2.

GetRichTextSize

Description
Gets the current font size setting for editing columns with the RichText edit style.

Applies to
DataWindow control

Syntax
Integer dwcontrol.GetRichTextSize ( REF integer size )

Return value
Returns an integer to indicate whether the column that you selected has the RichText edit style and whether the content has one or more sizes applied.

0 Success
-1 No RichText column is being edited
-2 The selected text is a mix of sizes

Usage
You can call this method from a button in a custom toolbar that you use to obtain current font settings for columns with the RichText edit style.

Examples
This example obtains the current size setting of the font to be used for editing columns with a RichText edit style:

Integer li_integer
Integer li_textsize
li_integer = dw_1.GetRichTextSize(li_textsize)

If 10 point text is selected when the above script is called, li_textsize is 10 and the method returns 0. If a mix of sizes is selected, li_textsize is 0 and the method returns -2.

SetRichTextSize

GetRichTextStyle

Description
Determines whether selected text or text at the cursor in a RichText column has a specified formatting.
**GetRichTextStyle**

Applies to

DataWindow control

Syntax

```powerbuilder
Integer dwControl.GetRichTextStyle(TextStyle style, REF boolean state)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control</td>
</tr>
</tbody>
</table>
| style       | Value for specifying a text style. Allowable values are: ...
| state       | Indicates whether the selected text or text at the cursor position has a style applied to it |

Return value

Returns an integer to indicate whether the column that you selected has the RichText edit style and whether the content has one or more styles applied.

- 0 Success
- -1 No RichText column is being edited
- -2 The selected text is a mix of styles

Usage

You can call this method from a button in a custom toolbar that you use to obtain the current font settings for columns with the RichText edit style.

Examples

This example determines whether a bold font is the current style setting for editing columns with a RichText edit style.

```powerbuilder
Integer li_style
Boolean lb_state
li_style = dw_1.GetRichTextStyle(bold!, lb_state)
```

If bold text is selected when the above script is called, the lb_state argument is true, and the method returns 0. If mixed text is selected, such as bold and italic, lb_state is true, and the method returns -2.

SetRichTextStyle
GetRow

Description
Reports the number of the current row in a DataWindow control or DataStore object.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder and Web DataWindow server component**

long dwcontrol.GetRow()

**Web DataWindow client control and Web ActiveX**

number dwcontrol.GetRow()

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or the child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns the number of the current row in dwcontrol. Returns 0 if no row is current and -1 if an error occurs.

If dwcontrol is null, in PowerBuilder and JavaScript the method returns null.

Current row not always displayed

The current row is not always a row displayed on the screen. For example, if the cursor is on row 7 column 2 and the user uses the scroll bar to scroll to row 50, the current row remains row 7 unless the user clicks row 50.

Examples

This statement returns the number of the current row in dw_Employee:

dw_employee.GetRow()

GetColumn
SetColumn
SetRow
## GetRowFromRowId

### Description

Gets the row number of a row in a DataWindow control or DataStore object from the unique row identifier associated with that row.

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

### Syntax

**PowerBuilder**

```powershell
long dwcontrol.GetRowFromRowId (long rowid, [DWBuffer buffer])
```

**Web ActiveX**

```powershell
number dwcontrol.GetRowFromRowId (number rowid, [number buffer])
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>rowid</td>
<td>A number specifying the row identifier for which you want the associated row number.</td>
</tr>
<tr>
<td>buffer</td>
<td>A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the DataWindow buffer that contains the row. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>

### Return value

Returns the row number in `buffer`. Returns 0 if the row number is not in the current buffer and –1 if an error occurs.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

### Usage

This method allows you to use a unique row identifier to retrieve the associated DataWindow or DataStore row number. The row identifier is not affected by operations (such as Insert, Delete, or Filter) that might change the original order (and consequently the row numbers) of the rows in the DataWindow or DataStore.

### Row identifiers

The row identifier is relative to the DataWindow that currently owns the row.
This example uses the row identifier previously obtained using the `GetRowIdFromRow` method to retrieve the row’s number after the original order of the rows in the DataWindow has changed.

```plaintext
long ll_rowid
long ll_rownumber

ll_rowid = dw_1.GetRowIdFromRow(dw_1.GetRow())
// suppose original order of rows changes...
ll_rownumber = dw_1.GetRowFromRowId(ll_rowid)
```

**GetRowIdFromRow**

**Description**

Gets the unique row identifier of a row in a DataWindow control or DataStore object from the row number associated with that row.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```plaintext
long dwcontrol.GetRowIdFromRow (long rownumber {, DWBuffer buffer })
```

**Web ActiveX**

```plaintext
number dwcontrol.GetRowIdFromRow (number rownumber, number buffer )
```

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to a DataWindow control, DataStore, or the child DataWindow.
`rownumber` | A number specifying the row number for which you want the associated row identifier.
`buffer` (optional) | A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the DataWindow buffer that contains the row. For a list of valid values, see DWBuffer on page 478.
GetSelectedRow

Return value
Returns the row identifier in buffer. Returns 0 if the row identifier is not in the current buffer and –1 if an error occurs.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage
The row identifier value is not the same as the row number value used in many DataWindow and DataStore function calls and should not be used for the row number value. Instead you should first convert the unique row identifier into a row number by calling GetRowFromRowId.

Row identifiers
The row identifier is relative to the DataWindow that currently owns the row.

Examples
This example retrieves the current row’s unique identifier:

```plaintext
long ll_rowid
ll_rowid = dw_emp.GetRowIDFromRow(dw_emp.GetRow())
```

See also
GetRow
GetRowFromRowId

GetSelectedRow

Description
Reports the number of the next highlighted row after a specified row in a DataWindow control or DataStore object.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```plaintext
long dwcontrol.GetSelectedRow ( long row )
```

**Web ActiveX**

```plaintext
number dwcontrol.GetSelectedRow ( number row )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the location of the row after which you want to search for the next selected row. Specify 0 to begin searching at the first row.</td>
</tr>
</tbody>
</table>
CHAPTER 9   Methods for the DataWindow Control

Return value
Returns the number of the first row that is selected after row in dwcontrol. Returns 0 if no row is selected after the specified row.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage
Rows are not automatically selected—that is, highlighted—when they become current. You can select a row by calling the SelectRow method. GetSelectedRow begins its search after the specified row. It does not matter whether row itself is selected.

Examples
This statement returns the number of the first row that is selected in dw_Employee:

    dw_Employee.GetSelectedRow(0)

This statement returns the number of the first row that is selected beginning with row 25 in dw_Employee:

    dw_Employee.GetSelectedRow(25)

See also
SelectRow

GetSQLPreview

Description
Reports the SQL statement that the DataWindow control is currently submitting to the database.

Obsolete method
GetSQLPreview is obsolete and will be discontinued in a future release. You should replace all references to GetSQLPreview as soon as possible. The SQL syntax is available as an argument in the DBError and SQLPreview events.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

    string dwcontrol.GetSQLPreview ( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow</td>
</tr>
</tbody>
</table>
GetSQLSelect

Return value

Returns the current SQL statement for `dwcontrol`. Returns the empty string (""") if an error occurs.

If `dwcontrol` is null, the method returns null.

See also

SetSQLPreview

GetSQLSelect

Description

Reports the SQL SELECT statement associated with a DataWindow if its data source is one that accesses a SQL database (such as SQL Select, Quick Select, or Query).

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
text
string `dwcontrol.GetSQLSelect` ( )
```

**Web ActiveX**

```powershell
text
string `dwcontrol.GetSQLSelect` ( )
```

Argument | Description
----------|-------------------------------------------------
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow

Return value

Returns the current SQL SELECT statement for `dwcontrol`. GetSQLSelect returns the empty string (""") if it cannot return the statement.

If `dwcontrol` is null, the method returns null.

Usage

When you want to change the SQL SELECT statement for a DataWindow or DataStore at runtime, you can use GetSQLSelect to save the current SELECT statement before making the change.

When you define a DataWindow, PowerBuilder stores a PowerBuilder SELECT statement (PBSELECT) with the DataWindow. If a database is connected and SetTransObject has been called for the DataWindow, then GetSQLSelect returns the SQL SELECT statement. Otherwise, GetSQLSelect returns the PBSELECT statement.
You can also use Describe to obtain the SQL SELECT statement. The 
DataWindow object’s Table.Select property holds the information.

Examples

The code saves the SELECT statement for dw_emp in the variable old_select. 
Then it adds a WHERE clause. The example assumes the old SELECT statement 
did not have one already:

```powerbuilder
string old_select, new_select, where_clause
// Get old SELECT statement
old_select = dw_emp.GetSQLSelect()

// Specify new WHERE clause
where_clause = "WHERE ..."
// Add the new where clause to old_select
new_select = old_select + where_clause

// Set the SELECT statement for the DW
dw_emp.SetSQLSelect(new_select)
```

See also
SetSQLSelect

---

**GetStateStatus**

**Description**

Retrieves the current status of the internal state flags for a DataWindow and 
places this information in a blob.

This method is used primarily in distributed applications.

**Obsolete method**

GetStateStatus is obsolete and will be discontinued in a future release. You 
should remove all use of GetStateStatus as soon as possible. This method was 
originally added to PowerScript to allow you to synchronize a source 
DataWindow with multiple target DataWindows. This technique is no longer 
supported.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
long dwcontrol.GetStateStatus ( blob cookie )
```
GetStateStatus

**Web ActiveX**

```powershell
number dwcontrol.GetStateStatus ( blob cookie )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control or DataStore for which you want to get state status</td>
</tr>
<tr>
<td><code>cookie</code></td>
<td>A variable in which you want to store a cookie that contains state information for the DataWindow</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if it fails.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

In situations where a single DataStore on a server acts as the source for multiple target DataWindows (or DataStores) on different clients, you can use GetChanges in conjunction with GetStateStatus to determine the likely success of SetChanges. This allows you to avoid shipping a change blob across the wire when SetChanges will fail anyway (because changes in the blob conflict with changes made previously by another client).

To determine the likely success of SetChanges, you need to:

1. Call the GetStateStatus method on the DataStore on which you want to do a SetChanges. GetStateStatus checks the state of the DataStore and makes the state information available in a reference argument called a cookie. The cookie is generally much smaller than a DataWindow change blob.

2. Send the cookie back to the client.

3. Call the GetChanges method on the DataWindow that contains the changes you want to apply, passing the cookie retrieved from GetStateStatus as a parameter. The return value from GetChanges indicates whether there are currently any potential conflicts between the state of the DataWindow blob and the state of the DataStore on which you want to execute SetChanges.

If the return value from GetChanges indicates that there are potential conflicts, you can then be certain that a subsequent call to SetChanges will fail if the FailOnAnyConflict! argument is specified. On the other hand, if the return value from GetChanges indicates no conflicts, the call to SetChanges may still fail, because the state of the Datastore may have changed since you called GetStateStatus and GetChanges.

For example, if another client session has called SetChanges or some other processing has been executed that altered the state of the DataStore since you retrieved the cookie, then SetChanges will fail.
The following example is a script for a remote object function. The script uses `GetStateStatus` to capture the state of a DataStore on the server into a cookie. Once the cookie has been created, it is returned to the client:

```powerbuilder
blob lblb_cookie
long ll_rv
ll_rv = ids_datastore.GetStateStatus(lblb_cookie)
return lblb_cookie
```

See also
- `GetChanges`
- `GetFullState`
- `SetChanges`
- `SetFullState`

### GetText

**Description**
Obtains the value in the edit control over the current row and column. When the user changes a value in a DataWindow, it is available in the edit control before it is accepted into the column.

** Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
string dwcontrol.GetText ( )
```

**Web ActiveX**

```powerbuilder
string dwcontrol.GetText ( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

**Return value**
Returns the value in the edit control over the current row and column in `dwcontrol`. The value might or might not have been accepted into the row and column. Returns the empty string (""") if no column is currently selected in `dwcontrol`.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.
GetTrans

Usage

The values in the rows and columns of a DataWindow are items in the DataWindow’s buffer. When a user edits a value in a row and column, the item value is transferred as text to an edit control in which the user can change the value. When the user leaves the column or when a script calls AcceptText, the text in the edit control is accepted into the column and becomes the value of the item in the buffer.

You do not need to call GetText in the script for the ItemChanged or ItemError event. To check the value entered in the edit control over the current row and column before allowing it to be accepted into the column, use the data argument.

To obtain the value stored in the DataWindow’s buffer for the row and column, use the GetItem method that corresponds with the datatype of the column.

Examples

This statement returns the text held in the edit control for the currently selected cell in dwEmp to the string variable selectedCell. The text might be a name or address for a column with the Edit edit style, Y or N for a column with the CheckBox edit style, or M or F for a column with the RadioButtons edit style that represents gender:

```
string selectedCell
selectedCell = dwEmp.GetText()
```

See also

SetText

GetTrans

Description

Gets the values for the DataWindow control or DataStore object’s internal transaction object and stores these values in the programmer-specified transaction object.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
integer dwcontrol.GetTrans ( transaction transaction )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
<tr>
<td>transaction</td>
<td>The name of the transaction object into which you want to put the values</td>
</tr>
</tbody>
</table>

698
Return value

Returns 1 if it succeeds and –1 if an error occurs. The return value is usually not used.

If any argument value is null, the method returns null.

Usage

The SetTrans method (not the SetTransObject method) sets the internal transaction object. If you have not called SetTrans, GetTrans will fail.

Use GetTrans when you want to get the values for the transaction object in order to modify them, as shown in the last example.

If you are using SetTransObject, which specifies transaction information using a programmer-specified transaction object, GetTrans will not report information about the programmer-specified transaction object currently in effect. (SetTransObject is the recommended connection method because it gives better application performance. See SetTrans and SetTransObject for more information.)

Examples

This example puts the values in the internal transaction object for dw_employee into the programmer-specified transaction object named object1:

```plaintext
transaction object1
object1 = CREATE transaction
dw_employee.GetTrans(object1)
```

The following statement puts the values in the internal transaction object for dw_employee into the default transaction object (SQLCA):

```plaintext
dw_employee.GetTrans(SQLCA)
```

The following statements change the database type and password of dw_employee. The first two statements create the transaction object emp_TransObj. The next two statements use the SetTrans method to set the values of SQLCA, and then use the GetTrans method to store the values of the current transaction object for dw_employee in emp_TransObj. The last two statements change the database type and password, and then the SetTrans method puts the revised values in the transaction object for dw_employee:

```plaintext
// Name the transaction object.
transaction emp_TransObj

// Create the transaction object.
emp_TransObj = CREATE transaction

// Set the internal transaction object.
dw_employee.SetTrans(SQLCA)

// Fill the new transaction object with original
GetUpdateStatus

// values from SQLCA.
dw_employee.GetTrans(emp_TransObj)

// Put revised values into the new transaction
// object.
// Change the database type.
emp_TransObj.DBMS = "Sybase"

// Change the password.
emp_TransObj.LogPass = "cam2"

// Associate the new transaction object with
// dw_employee, replacing SQLCA.
dw_employee.SetTrans(emp_TransObj)

See also
SetTrans

GetUpdateStatus

Description
Reports the row number and buffer of the row that is currently being updated
in the database. When called because of an error, GetUpdateStatus reports the
row that caused the error.

Obsolete method
GetUpdateStatus is obsolete and will be discontinued in a future release. You
should replace all references to GetUpdateStatus as soon as possible. The
update status is available as an argument in the DBError and SQLPreview
events.

Applies to
PowerBuilder DataWindow control, DataWindowChild object

Syntax
PowerBuilder
integer dwcontrol.GetUpdateStatus(long row, DWBuffer dwbuffer )

Argument | Description
--- | ---
dwcontrol | A reference to a DataWindow control or child DataWindow.
row | A variable that will store the number of the row that will be updated
| or for which an update was attempted.
Return value

Returns 1 if it succeeds and –1 if an error occurs. The number and buffer of the row currently being updated are stored in `row` and `dwbuffer`.

If any argument value is null, the method returns null.

Examples

These statements in the script for the DBError event for a DataWindow control obtain the text of the error message, display a message box with the number of the row in which the error occurred and the error message, and then make the row with the error the current row.

Additional code in the `IF` statement considers the case of the bad row being in the filter or delete buffer. If the row is in the filter buffer, the script changes the filter so that the user can edit the row in the primary buffer. If the row is in the delete buffer, the message box displays a slightly different title:

```plaintext
long row_number, row_key
dwBuffer buffer_type
string message_text, message_title, old_filter

// Get the error message text and set the title
message_text = DBErrorMessage()
message_title = "Database Error Updating Row"

// Get the row in which the error occurred
This.GetUpdateStatus(row_number, buffer_type)

IF buffer_type = Filter! THEN
    old_filter = This.Describe("DataWindow.Filter")
    row_key = This.GetItemNumber(row_number, & "emp_id", Filter!, false)

    This.SetFilter("(" + old_filter + ")" + & "OR emp_id = " + String(row_key))
    This.Filter()

    // Error row is now last row in primary buffer
    row_number = This.RowCount()

ELSIF buffer_type = Delete! THEN
    message_title = "Database Error Deleting Row"

END IF
```
GetValidate

// Display the location of the error and the error message.
MessageBox(message_title + &
    String(row_number), message_text)

IF buffer_type <> Delete! THEN
    // Make the row with the error the current row.
    This.ScrollToRow(row_number)
END IF

// Return 1 from the DBError event
// (do not display error message) because we've already displayed a message
RETURN 1

See also GetItemStatus

GetValidate

Description
Obtains the validation rule for a column in a DataWindow.

GetValidateByColNum
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

- string dwcontrol.GetValidate ( string column )
- string dwcontrol.GetValidate ( integer column )

**Web DataWindow server component**

- string dwcontrol.GetValidate ( string column )
- string dwcontrol.GetValidateByColNum ( short column )

**Web ActiveX**

- string dwcontrol.GetValidate ( string column )
- string dwcontrol.GetValidate ( number column )
CHAPTER 9  Methods for the DataWindow Control

Return value

Returns the validation rule for column in dwcontrol. Returns the empty string ("") if no validation criteria are defined for the column.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

You can use GetValidate to save the current validation rule before calling SetValidate to change the rule temporarily.

Examples

These statements change the validation rule for column 7 in the DataWindow control dw_Employee to Rule2:

```powershell
string Rule1, Rule2 = "Long(GetText()) > 15000"
Rule1 = dw_Employee.GetValidate(7)
dw_Employee/SetValidate(7, Rule2)
```

See also

SetValidate

GetValue

Description

Obtains the value of an item in a value list or code table associated with a column in a DataWindow.

GetValueByColNum

A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

GetValidate
GetValue

Syntax

PowerBuilder

string dwcontrol.GetValue ( string column, integer index )
string dwcontrol.GetValue ( integer column, integer index )

Web DataWindow server component

string dwcontrol.GetValue ( string column, short index )
string dwcontrol.GetValueByColNum ( short column, short index )

Web ActiveX

string dwcontrol.GetValue ( string column, number index )
string dwcontrol.GetValue ( number column, number index )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>column</td>
<td>The column for which you want the item. Column can be a column number (integer) or a column name (string).</td>
</tr>
<tr>
<td>index</td>
<td>The number of the item in the value list or the code table for the edit style.</td>
</tr>
</tbody>
</table>

Return value

Returns the item identified by index in the value list or the code table associated with column of dwcontrol. If the item has a display value that is not the actual value, GetValue returns a tab-separated string consisting of:

displayvalue[tab]codevalue

Returns the empty string (""") if the index is not valid or the column does not have a value list or code table.

If any argument value is null, in PowerBuilder and JavaScript the method returns null.

Usage

You can use GetValue to find out the values associated with the following edit styles: CheckBox, RadioButton, DropDownListBox, Edit Mask, and Edit. If the edit style has a code table in which each value in the list has a display value and a data value, GetValue reports both values.

GetValue does not get values from a DropDownDataWindow code table.

You can parse the return value by searching for the tab character (ASCII 09). In PowerBuilder, search for ~t.

Examples

If the value list for column 7 of dw_employee contains Full Time, Part Time, Retired, and Terminated, these statements return the value of item 3 (Retired):

```powerbuilder
string Status
Status = dw_employee.GetValue(7,3)
```

704 PowerBuilder
If the value list for the column named product of dw_employee is Widget[tab]1, Gadget[tab]2, the following code returns Gadget[tab]2 and saves the display value in a string variable:

```java
string ls_prodinfo, ls_prodname, ls_prodnum
integer li_tab

ls_prodinfo = dw_employee.GetValue("product", 2)
li_tab = Pos(ls_prodinfo, ",", 1)
ls_prodname = Left(ls_prodinfo, li_tab - 1)
ls_prodnum = Mid(ls_prodinfo, li_tab + 1)
```

ClearValues
SetValue

### GroupCalc

**Description**
Recalculates the breaks in the grouping levels in a DataWindow.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```java
integer dwcontrol.GroupCalc ()
```

**Web DataWindow server component**

```java
short dwcontrol.GroupCalc ()
```

**Web ActiveX**

```java
number dwcontrol.GroupCalc ()
```

**Argument | Description**
---|------------------|
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.
Hide

Usage

Use GroupCalc to force the DataWindow object to recalculate the breaks in the grouping levels after you have added or modified rows in a DataWindow.

GroupCalc does not sort the data before it recalculates the breaks. Therefore, unless you populated the DataWindow in a sorted order, call the Sort method to sort the data before you call GroupCalc.

Examples

This code imports new rows from a file into the DataWindow dw_emp and then recalculates the group breaks for dw_emp:

```powerbuilder
  dw_emp.ImportFile("d:\employee.txt")
  dw_emp.SetRedraw(false)
  dw_emp.SetSort("1A")
  dw_emp.Sort()
  dw_emp.GroupCalc()
  dw_emp.SetRedraw(true)
```

See also

Sort

Hide

Description

Makes an object or control invisible. Users cannot interact with an invisible object. It does not respond to any events, so the object is also, in effect, disabled.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

```powerbuilder
  Integer objName.Hide()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objName</td>
<td>The name of the object or control you want to make invisible</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. If objName is null, Hide returns null.

Usage

Inherited from GraphicObject. For information, see Hide in the PowerScript Reference.
**ImportClipboard**

*Description*  
Inserts data into a DataWindow control or DataStore object from tab-separated, comma-separated, or XML data on the clipboard.

*Applies to*

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

*Syntax*

**PowerBuilder**

```c
long dwcontrol.ImportClipboard ( {saveastype importtype}, { long startrow, long endrow, long startcolumn, long endcolumn, long dwstartcolumn } )
```

**Web ActiveX**

```c
number dwcontrol.ImportClipboard ( number importtype, number startrow, number endrow, number startcolumn, number endcolumn, number dwstartcolumn )
```

*Argument | Description*
--- | ---
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow.
`importtype` (optional for PowerBuilder) | An enumerated value of the SaveAsType DataWindow constant or a number representing that value (see SaveAsType on page 486). Valid import type arguments for ImportClipboard are:  
Text!  
CSV!  
XML!  
If you want to generate an XML trace file, the XML! argument is required.
`startrow` (optional for PowerBuilder) | The number of the first detail row in the clipboard that you want to copy. The default is 1.  
For default XML import, if `startrow` is supplied, the first $N$ (`startrow` -1) elements are skipped, where $N$ is the DataWindow row size.  
For template XML import, if `startrow` is supplied, the first (`startrow` -1) occurrences of the repetitive row mapping defined in the template are skipped.
### ImportClipboard

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>endrow</td>
<td>The number of the last detail row in the clipboard that you want to copy. The default is the rest of the rows. For default XML import, if <code>endrow</code> is supplied, import stops when ( N \times endrow ) elements have been imported, where ( N ) is the DataWindow row size. For template XML import, if <code>endrow</code> is supplied, import stops after <code>endrow</code> occurrences of the repetitive row mapping defined in the template have been imported.</td>
</tr>
<tr>
<td>startcolumn</td>
<td>The number of the first column in the clipboard that you want to copy. The default is 1. For default XML import, if <code>startcolumn</code> is supplied, import skips the first <code>(startcolumn - 1)</code> elements in each row. This argument has no effect on template XML import.</td>
</tr>
<tr>
<td>endcolumn</td>
<td>The number of the last column in the clipboard that you want to copy. The default is the rest of the columns. For default XML import, if <code>endcolumn</code> is supplied and is smaller than ( N ), where ( N ) is the DataWindow row size, import skips the last ( (N - endcolumn) ) elements in each row. This argument has no effect on template XML import.</td>
</tr>
<tr>
<td>dwstartcolumn</td>
<td>The number of the first column in the DataWindow control or DataStore that should receive data. The default is 1. This argument is supported for default and template XML import.</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of rows that were imported if it succeeds and one of the following negative integers if an error occurs:

-1  No rows or `startrow` value supplied is greater than the number of rows in the string

-3  Invalid argument

-4  Invalid input

-11 XML Parsing Error; XML parser libraries not found or XML not well formed

-12 XML Template does not exist or does not match the DataWindow

-13 Unsupported DataWindow style for import

-14 Error resolving DataWindow nesting
Usage

The clipboard data must be formatted in tab-separated or comma-separated columns or in XML. The datatypes and order of the DataWindow object’s columns must match the data on the clipboard.

If an XML or CSV column contains a leading double quote, it is assumed to be part of the column value. A leading double quote has to be closed to mark the end of an item.

All the arguments of this function are optional. You do not need to specify the importtype argument. The startcolumn and endcolumn arguments control the number of imported columns and the number of columns in the DataWindow that are affected. The dwstartcolumn argument specifies the first DataWindow column to be affected. The following formula calculates the last column to be affected.

\[ \text{dwstartcolumn} + (\text{endcolumn} - \text{startcolumn}) \]

ImportClipboard does not support Crosstab DataWindow objects.

Examples

This statement copies all data in the clipboard to the DataWindow dw_employee starting at the first column:

`dw_employee.ImportClipboard()`

This statement copies all data in the clipboard to the DataWindow dw_employee starting at the first column and specifies that the data is in XML format:

`dw_employee.ImportClipboard(XML!)`

This statement imports rows 1 to 200 of the XML data on the clipboard, ignoring any template mappings before column 5:

`dw_employee.ImportClipboard(XML!, 1, 200, 0, 0, 5)`

This statement inserts data from the clipboard into the DataWindow dw_employee. It copies rows 2 through 30 and columns 3 through 8 on the clipboard to the DataWindow beginning in column 5. It adds 29 rows to the DataWindow with data in columns 5 through 10:

`dw_employee.ImportClipboard(2,30,3,8,5)`

See also

ImportFile
ImportString
**ImportFile**

**Description**
Inserts data into a DataWindow control or DataStore from a file. The data can be tab-separated text, comma-separated text, XML, or dBase format 2 or 3.

**Applies to**
- **DataWindow type** | **Method applies to**
  - PowerBuilder | DataWindow control, DataWindowChild object, DataStore object
  - Web ActiveX | DataWindow control, DataWindowChild object

**Syntax**

**PowerBuilder**

```
long dwcontrol.ImportFile ( {saveastype importtype}, string filename {, long startrow {, long endrow {, long startcolumn {, long endcolumn {, long dwstartcolumn } } } } }
```

**Web ActiveX**

```
number dwcontrol.ImportFile ( number importtype, string string, number startrow, number endrow, number startcolumn, number endcolumn, number dwstartcolumn )
```

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to a DataWindow control or DataStore
`importtype` (optional for PowerBuilder) | An enumerated value of the SaveAsType DataWindow constant or a number representing that value (see SaveAsType on page 486). If this argument is specified, the `filename` argument can be specified without an extension. Valid type arguments for ImportFile are:
  - Text!
  - CSV!
  - XML!
  - DBase2!
  - DBase3!

`filename` | A string whose value is the name of the file from which you want to copy data. The file must be an ASCII, tab-separated file (TXT) or a comma-separated file (CSV), Extensible Markup Language file (XML), or dBase format 2 or 3 file (DBF). Specify the file’s full name. If the optional `importtype` is not specified, the name must end in the appropriate extension.
If `filename` is an empty string, or if it is null, ImportFile displays the File Open dialog box and allows the user to select a file. The remaining arguments are ignored.
### Events

ImportFile may trigger an ItemError event.

### Return value

Long. Returns the number of rows that were imported if it succeeds and one of the following negative integers if an error occurs:

- **-1** No rows or startrow value supplied is greater than the number of rows in the file
- **-2** Empty file
- **-3** Invalid argument

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>startrow</strong> (optional for</td>
<td>The number of the first detail row in the file that you want to copy. The default is 1.</td>
</tr>
<tr>
<td>PowerBuilder)</td>
<td>For default XML import, if startrow is supplied, the first (N) ((startrow - 1)) elements are skipped, where (N) is the DataWindow row size.</td>
</tr>
<tr>

</tr>
<tr>
<td><strong>dwstartcolumn</strong> (optional</td>
<td>The number of the first column in the DataWindow control or DataStore that should receive data. The default is 1.</td>
</tr>
<tr>
<td>for PowerBuilder)</td>
<td>This argument is supported for default and template XML import.</td>
</tr>
</tbody>
</table>
-4 Invalid input
-5 Could not open the file
-6 Could not close the file
-7 Error reading the text
-8 Unsupported file name suffix (must be *.txt, *.csv, *.dbf or *.xml)
-10 Unsupported dBase file format (not version 2 or 3)
-11 XML Parsing Error: XML parser libraries not found or XML not well formed
-12 XML Template does not exist or does not match the DataWindow
-13 Unsupported DataWindow style for import
-14 Error resolving DataWindow nesting
-15 File size exceeds limit

Usage
The format of the file can be indicated by specifying the optional importtype parameter, or by including the appropriate file extension.

The file should consist of rows of data. If the file includes column headings or row labels, set the startrow and startcolumn arguments to skip them. The datatypes and order of the DataWindow object’s columns must match the columns of data in the file.

The startcolumn and endcolumn arguments control the number of columns imported from the file and the number of columns in the DataWindow that are affected. The dwstartcolumn argument specifies the first DataWindow column to be affected. The following formula calculates the last DataWindow to be affected.

\[ dwstartcolumn + (endcolumn - startcolumn) \]

To let users select the file to import, specify a null string for filename. PowerBuilder displays the Select Import File dialog box. A drop-down list lets the user select the type of file to import.

Specifying a null string for filename
If you specify a null string for filename, the remaining arguments are ignored. All the rows and columns in the file are imported.
Double quotes  The location and number of double quote marks in a field in a tab-separated file affect how they are handled when the file is imported. If a string is enclosed in one pair of double quotes, the quotes are discarded. If it is enclosed in three pairs of double quotes, one pair is retained when the string is imported. If the string is enclosed in two pairs of double quotes, the first pair is considered to enclose a null string, and the rest of the string is discarded.

When there is a double quote at the beginning of a string, any characters after the second double quote are discarded. If there is no second double quote, the tab or comma character delimiting the fields is not recognized as a field separator and all characters up to the next occurrence of a double quote, including a carriage return, are considered to be part of the string. A validation error is generated if the combined strings exceed the length of the first string.

Double quotes after the first character in the string are rendered literally. Here are some examples of how tab-separated strings are imported into a two-column DataWindow:

<table>
<thead>
<tr>
<th>Text in file</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Joe&quot; TAB &quot;Donaldson&quot;</td>
<td>Joe Donaldson</td>
</tr>
<tr>
<td>Bernice TAB &quot;&quot;&quot;Ramakrishnan&quot;&quot;&quot;&quot;</td>
<td>Bernice &quot;Ramakrishnan&quot;</td>
</tr>
<tr>
<td>&quot;&quot;Mary&quot;&quot; TAB &quot;&quot;Li&quot;&quot;</td>
<td>Empty cells</td>
</tr>
<tr>
<td>&quot;Mich&quot;ael TAB &quot;&quot;Mariam&quot;&quot;&quot;&quot;</td>
<td>Mich &quot;Mariam&quot;</td>
</tr>
<tr>
<td>&quot;Amy TAB Doherty&quot;</td>
<td>Amy&lt;TAB&gt;Doherty in first cell, second cell empty</td>
</tr>
</tbody>
</table>
| """""" TAB 4"""" | 3"""""" 4""

If an XML or CSV column contains a leading double quote, it is assumed to be part of the column value. A leading double quote has to be closed to mark the end of an item.

Examples

This statement inserts all the data in the file D:\TMP\EMPLOYEE.CSV into dw_employee starting at the first column:

```none
dw_employee.ImportFile("D:\TMP\EMPLOYEE.CSV")
```

This statement inserts all the data in the file D:\TMP\EMPLOYEE.XML into dw_employee starting at the first column:

```none
dw_employee.ImportFile(XML!,"D:\TMP\EMPLOYEE")
```
**ImportString**

The following statements are equivalent. Both import the contents of the XML file named *myxmldata*:

```powerbuilder
dw_control.ImportFile("myxmldata.xml")
dw_control.ImportFile(XML!, "myxmldata")
```

This statement imports rows 1 to 200 of *employee.xml*, ignoring any template mappings before column 5:

```powerbuilder
dw_employee.ImportFile(XML!,"D:\TMP\EMPLOYEE.XML", 1, 200, 0, 0, 5)
```

This statement imports the data from the file *D:\TMP\EMPLOYEE.TXT* into the DataWindow *dw_employee*. It copies rows 2 through 30 and columns 3 through 8 in the file to the DataWindow beginning in column 5. The result is 29 rows added to the DataWindow with data in columns 5 through 10:

```powerbuilder
dw_employee.ImportFile("D:\TMP\EMPLOYEE.TXT", & 2, 30, 3, 8, 5)
```

- ImportString

---

**ImportString**

**Description**

Inserts data into a DataWindow control or DataStore from tab-separated, comma-separated, or XML data in a string.

**ImportStringEx**

A separate method name is provided as an alternative syntax for Web DataWindow components that cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>

</tr>
<tr>
<td>startcolumn (optional for PowerBuilder)</td>
<td>The number of the first column in the string that you want to copy. The default is 1. For default XML import, if startcolumn is supplied, import skips the first (startcolumn - 1) elements in each row. This argument has no effect on template XML import.</td>
</tr>
<tr>
<td>endcolumn (optional for PowerBuilder)</td>
<td>The number of the last column in the string that you want to copy. The default is the rest of the columns. For default XML import, if endcolumn is supplied and is smaller than N, where N is the DataWindow row size, import skips the last (N - endcolumn) elements in each row. This argument has no effect on template XML import.</td>
</tr>
<tr>
<td>dwstartcolumn (optional for PowerBuilder)</td>
<td>The number of the first column in the DataWindow control or DataStore that should receive data. The default is 1. This argument is supported for default and template XML import.</td>
</tr>
</tbody>
</table>

**Events**

ImportString may trigger an ItemError event.

**Return value**

Returns the number of rows that were imported if it succeeds and one of the following negative integers if an error occurs:

- **-1** No rows or startrow value supplied is greater than the number of rows in the string
- **-3** Invalid argument
- **-4** Invalid input
- **-11** XML Parsing Error; XML parser libraries not found or XML not well formed
- **-12** XML Template does not exist or does not match the DataWindow
- **-13** Unsupported DataWindow style for import
- **-14** Error resolving DataWindow nesting
Usage

All the arguments of this function except *string* are optional. You do not need to specify the *importtype* argument.

The string must be formatted in tab-separated or comma-separated columns or in XML. For TXT and CSV files, the format of the string is the same as if the data came from an ASCII file, and each line must end with a carriage return and a newline character (~r~n). If the string has four tab-separated columns, one line might look like for a tab-separated string:

\[
\text{col1\_data}\text{-t} \text{col2\_data}\text{-t} \text{col3\_data}\text{-t} \text{col4\_data}\text{-r\-n}
\]

For a DataWindow control or DataStore, the string should consist of rows of data. If the data includes column headings or row labels, set the *startrow* and *startcolumn* arguments to skip them. The datatypes and order of the DataWindow object’s columns must match the columns of data in the string.

The *startcolumn* and *endcolumn* arguments control the number of columns imported from the string and the number of columns in the DataWindow that are affected. The *dwstartcolumn* argument specifies the first DataWindow column to be affected. The following formula calculates the last DataWindow column to be affected.

\[
dwstartcolumn + (\text{endcolumn} - \text{startcolumn})
\]

If string data to be assigned to a single row and column has multiple lines (indicated by line-ending characters in the import string), you must quote the string data using ~". Do not use single quotes.

This example of a valid tab-separated import string assigns multiline values to each row in column 2:

\[
\text{ls\_s} = \&
\text{"1\-t\-"Mickey\-r\-nMinnie\-r\-nGoofy\-~r\-n" \-r\-n\" + \&}
\text{"2\-t\-"Susan\-r\-nMary\-r\-nMarie\-~r\-n" \-r\-n\" + \&}
\text{"3\-t\-"Chris\-r\-nBen\-r\-nMike\-~r\-n" \-r\-n\" + \&}
\text{"4\-t\-"Mott\-r\-nBarber\-r\-nPicard\-~r\-n" "}
\]

If an XML or CSV column contains a leading double quote, it is assumed to be part of the column value. A leading double quote has to be closed to mark the end of an item.

ImportString does not support Crosstab DataWindow objects.

Examples

These statements copy all data in the string *ls\_Emp\_Data* to the DataWindow control *dw\_employee* starting at the first column:

\[
\text{string \ ls\_Emp\_Data}
\ls\_Emp\_Data = \ldots
\text{dw\_employee.\textbf{ImportString}(ls\_Emp\_Data)}
\]
This statement stores data in the string `ls_text` and imports it into the DataWindow `dw_employee`. The DataWindow is a report of department 100 and start and end dates of personnel. The string includes the department number and other information, which is not imported. `ImportString` imports rows 2 through 10 and columns 2 through 5 in the string to the DataWindow beginning in column 2. The result is 9 rows added to the DataWindow with data in columns 5 through 8:

```plaintext
string ls_text

ls_text = "Dept-tLName-t FName-tStart" &
    + "-tEnd-tAmount-tOutcome -r-n"
ls_text = ls_text + &
    "100-tJones-tMary-tApr88-tJul94-t40-tG-r-n"
ls_text = ls_text + &
    "100-tMarsh-tMarsha-tApr89-tJan92-t35-tG-r-n"
ls_text = ls_text + &
    "100-tJames-tHarry-tAug88-tMar93-t22-tM-r-n"
...
ls_text = ls_text + &
    "100-tWorth-tFrank-tSep87-tJun94-t55-tE-r-n"

dw_employee.ImportString(ls_text, 2, 10, 2, 5, 5)
```

This statement imports rows 1 to 200 of the data in the XML string `ls_emp`, ignoring any template mappings before column 5:

```plaintext
dw_employee.ImportString(ls_emp, 1, 200, 0, 0, 5)
```

- `ImportFile`

---

**InsertDocument**

**Description**

Inserts a rich text format or plain text file into a DataWindow control or DataStore object.

The new content is added in one of two ways:

- The new content can be inserted at the insertion point.
- The new content can replace all existing content.
CHAPTER 9  Methods for the DataWindow Control

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.InsertDocument ( string filename, boolean clearflag, FileType filetype)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore object. The DataWindow object in the DataWindow control or DataStore must be a RichTextEdit DataWindow.</td>
</tr>
<tr>
<td>filename</td>
<td>A string whose value is the name of the file you want to display in the RichTextEdit control. Filename can include the file’s path.</td>
</tr>
<tr>
<td>clearflag</td>
<td>A boolean value specifying whether the new file will replace the current contents of the control. Values are:</td>
</tr>
<tr>
<td></td>
<td>• True – Replace the current contents with the file.</td>
</tr>
<tr>
<td></td>
<td>• false – Insert the file into the existing contents at the insertion point.</td>
</tr>
<tr>
<td>filetype</td>
<td>A value of the FileType enumerated datatype specifying the type of file being opened. Values are:</td>
</tr>
<tr>
<td></td>
<td>• FileTypeRichText! – (Default) The file being opened is in rich text format (RTF).</td>
</tr>
<tr>
<td></td>
<td>• FileTypeText! – The file being opened is plain ASCII text (TXT).</td>
</tr>
<tr>
<td></td>
<td>• FileTypeHTML! – The file being opened is in HTML format (HTM or HTML)</td>
</tr>
<tr>
<td></td>
<td>• FileTypeDoc! – The file being opened is in Microsoft Word format (DOC)</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and −1 if an error occurs. If any argument’s value is null, InsertDocument returns null.

Usage

When the control supports headers and footer (the HeaderFooter property is set to true), inserting a document can replace, but not add to, existing header and footer text. You must set clearflag to true to replace the existing header and footer text with header and footer text from the inserted document.

Not all RTF formatting is supported. PowerBuilder supports version 1.6 of the RTF standard, except for the following:

- No support for formatted tables
- No drawing controls
InsertRow

Any unsupported formatting is ignored.

**PowerBuilder environment**
For use with other PowerBuilder RichTextEdit controls, see InsertDocument in the *PowerScript Reference*.

**Examples**
This example inserts a document into a RichTextEdit DataWindow:

```pascal
integer rtn
rtn = dw_1.InsertDocument("c:\pb\test.rtf", &false, FileTypeRichText!)
```

**See also**
DataSource in the *PowerScript Reference*

InsertPicture in the *PowerScript Reference*

### InsertRow

**Description**
Inserts a row in a DataWindow or DataStore. If any columns have default values, the row is initialized with these values before it is displayed.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder and Web DataWindow server component**

```pascal
long dwcontrol.InsertRow ( long row )
```

**Web DataWindow client control and Web ActiveX**

```pascal
number dwcontrol.InsertRow ( number row )
```

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow.
`row` | A value identifying the row before which you want to insert a row. To insert a row at the end, specify 0.
Return value
Returns the number of the row that was added if it succeeds and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null. If there is no DataWindow object assigned to the DataWindow control or DataStore, this method returns –1.

Usage
InsertRow simply inserts the row without changing the display or the current row. To scroll to the row and make it the current row, call ScrollToRow. To simply make it the current row, call SetRow.

A newly inserted row (with a status flag of New!) is not included in the modified count until data is entered in the row (its status flag becomes NewModified!).

Web DataWindow client control Calling InsertRow causes the new status of the data to be sent back to the server where the data is retrieved again and the row is inserted. Then the page is reloaded.

If the DataWindow object has retrieval arguments, they must be specified in the HTMLGen.SelfLinkArgs property. For more information, see the HTMLGen.property, the Retrieve method, and the DataWindow Programmers Guide.

All methods that reload the page perform an AcceptText before sending data back to the server. If the method fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.

Examples
This statement inserts an initialized row before row 7 in dw_Employee:

dw_Employee.InsertRow(7)

This example inserts an initialized row after the last row in dw_employee, then scrolls to the row, which makes it current:

long ll_newrow
ll_newrow = dw_employee.InsertRow(0)
dw_employee.ScrollToRow(ll_newrow)

DeleteRow
Update
**IsExpanded**

**Description**
Performs a test to see whether a group in a TreeView DataWindow with the specified TreeView level is expanded, and whether the group includes the specified row.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

`PowerBuilder

Boolean dw_control.IsExpanded(long row, long groupLevel)`

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dw_control</code></td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
<tr>
<td><code>row</code></td>
<td>The number of the row that belongs to the group</td>
</tr>
<tr>
<td><code>groupLevel</code></td>
<td>The TreeView level of the group</td>
</tr>
</tbody>
</table>

**Return value**
Returns true if the group is expanded and false if the group is not expanded. `IsExpanded` also returns false if the DataWindow is not a TreeView DataWindow or the `row` or `groupLevel` is invalid.

**Usage**
A TreeView DataWindow has several TreeView level bands (groups) that can be expanded and collapsed. You can use the `IsExpanded` method to test whether or not a group in a TreeView DataWindow is expanded.

**Examples**
The following example performs a test to determine whether the group that contains row 3 at TreeView level 2 is expanded:

```java
boolean lb_expanded
lb_expanded = dw_treeview.IsExpanded(3,2)
```

**See also**
Expand
ExpandAll
ExpandAllChildren
ExpandLevel
IsRowSelected

Description
Determines whether a row is selected in a DataWindow. A selected row is highlighted using reverse video.

Applies to

| DataWindow type | Web | Method applies to | Client control |

Syntax

**Web DataWindow client control**

```java
boolean dwcontrol.IsSelected ( number row )
```

Return value

Returns true if `row` in `dwcontrol` is selected and false if it is not selected. If `row` is greater than the number of rows in `dwcontrol` or is 0 or negative, `IsRowSelected` also returns false.

Usage

You can call `IsRowSelected` in a script for the Clicked event to determine whether the row the user clicked was selected. With `IsRowSelected` and `SelectRow`, you can highlight a row on the client without causing a postback.

Examples

This code calls `IsRowSelected` to test whether the clicked row is selected. If the row is selected, `SelectRow` deselects it; if it is not selected, `SelectRow` selects it:

```java
if (rowNumber > 0)
{
    if (dw_1.IsRowSelected(rowNumber))
        dw_1.SelectRow(rowNumber, false);
    else
        dw_1.SelectRow(rowNumber, true);
}
```

See also

`SelectRow`
**isSelected**

**Description**
Determines whether a row is selected in a DataWindow or DataStore. A selected row is highlighted using reverse video.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```java
boolean dwcontrol.IsSelected (long row)
```

**Web ActiveX**

```java
boolean dwcontrol.IsSelected (number row)
```

**Argument | Description**
---|---
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow
`row` | A value identifying the row you want to test to see if it is selected

**Return value**

Returns true if `row` in `dwcontrol` is selected and false if it is not selected. If `row` is greater than the number of rows in `dwcontrol` or is 0 or negative, `IsSelected` also returns false.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

You can call `IsSelected` in a script for the Clicked event to determine whether the row the user clicked was selected.

**Examples**

This code calls `IsSelected` to test whether the current row in `dw_employee` is selected. If the row is selected, `SelectRow` deselects it; if it is not selected, `SelectRow` selects it:

```java
long CurRow
boolean result

CurRow = dw_employee.GetRow()
result = dw_employee.IsSelected(CurRow)

IF result THEN
    dw_employee.SelectRow(CurRow, false)
ELSE
    dw_employee.SelectRow(CurRow, true)
END IF
```
This code uses the NOT operator on the return value of `IsSelected` to accomplish the same result as the IF/THEN/ELSE statement above:

```powershell
integer CurRow
boolean result
CurRow = dw_employee.GetRow()
dw_employee.SelectRow(CurRow, &
    NOT dw_employee.IsSelected(CurRow))
```

**See also**

SelectRow

---

**LineCount**

**Description**

Determines the number of lines in an edit control that allows multiple lines.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powershell
long dwcontrol.LineCount ()
```

**Web ActiveX**

```powershell
number dwcontrol.LineCount ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of lines in `dwcontrol` if it succeeds and -1 if an error occurs. If `dwcontrol` is null, `LineCount` returns null.

**Usage**

`LineCount` counts each visible line, whether it was the result of wrapping or carriage returns.

When you call `LineCount` for a DataWindow, it reports the number of lines in the edit control over the current row and column. A user can enter multiple lines in a DataWindow column only if it has a text datatype and its box is large enough to display those lines.

The size of the column’s box determines the number of lines allowed in the column. When the user is typing, lines do not wrap automatically; the user must press Enter to type additional lines.
ModifiedCount

**PowerBuilder environment**
For use with other PowerBuilder controls, see LineCount in the *PowerScript Reference*.

**Examples**
If the MultiLineEdit mle_Instructions has 9 lines, this example sets li_Count to 9:

```powerbuilder
integer li_Count
li_Count = mle_Instructions.LineCount()
```

These statements display a MessageBox if fewer than two lines have been entered in the MultiLineEdit mle_Address:

```powerbuilder
integer li_Lines
li_Lines = mle_Address.LineCount()
IF li_Lines < 2 THEN
    MessageBox("Warning", "2 lines are required.")
END IF
```

**ModifiedCount**
Reports the number of rows that have been modified but not updated in a DataWindow or DataStore.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

<table>
<thead>
<tr>
<th><strong>PowerBuilder and Web DataWindow server component</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>long dwcontrol.ModifiedCount()</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Web DataWindow client control and Web ActiveX</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>number dwcontrol.ModifiedCount()</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Argument</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>
CHAPTER 9 Methods for the DataWindow Control

Return value

Returns the number of rows that have been modified in the primary buffer. Returns 0 if no rows have been modified or if all modified rows have been updated in the database table. Returns –1 if an error occurs.

If dwcontrol is null, in PowerBuilder and JavaScript the method returns null.

Usage

ModifiedCount reports the number of rows that are scheduled to be added or updated in the database table associated with a DataWindow or DataStore. This includes rows in the primary and filter buffers.

A newly inserted row (with a status flag of New!) is not included in the modified count until data is entered in the row (its status flag becomes NewModified!).

The DeletedCount method counts the number of rows in the deleted buffer. The RowCount method counts the total number of rows in the primary buffer.

Examples

If five rows in dw_Employee have been modified but not updated in the associated database table or filtered out of the primary buffer, the following code sets ll_Rows equal to 5:

```pascal
long ll_Rows
ll_Rows = dw_Employee.ModifiedCount()
```

If any rows in dw_Employee have been modified but not updated in the associated database table, this statement updates the database table associated with the dw_employee DataWindow control:

```pascal
IF dw_employee.ModifiedCount() > 0 THEN &
   dw_employee.Update()
```

Retrieve
RowCount
Update
Modify

Description
Modifies a DataWindow object by applying specifications, given as a list of instructions, that change the DataWindow object’s definition.

You can change appearance, behavior, and database information for the DataWindow object by changing the values of properties. You can add and remove controls from the DataWindow object by providing specifications for the controls.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder, Web DataWindow, and Web ActiveX**

```powershell
string dwcontrol.Modify ( string modstring )
```

Argument | Description
----------|---------------------------------------------------------
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow.
`modstring` | A string whose value is the specifications for the modification. See Usage for appropriate formats.

Return value

Returns the empty string ("") if it succeeds and an error message if an error occurs. The error message takes the form "Line n Column n incorrect syntax". The character columns are counted from the beginning of the compiled text of `modstring`.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Modify lets you make many of the same settings in a script that you would make in the DataWindow painter. Typical uses for Modify are:

- Changing colors, text settings, and other appearance settings of controls
- Changing the update status of different tables in the DataWindow so that you can update more than one table
- Modifying the WHERE clause of the DataWindow object’s SQL SELECT statement
- Turning on Query mode or Prompt For Criteria so users can specify the data they want
• Changing the status of Retrieve Only As Needed
• Changing the data source of the DataWindow object
• Controlling the Print Preview display
• Deleting and adding controls (such as lines or bitmaps) in the DataWindow object

Each of these uses is illustrated in the Examples for this method.

You can use three types of statements in `modstring` to modify a DataWindow object.

<table>
<thead>
<tr>
<th>Statement type</th>
<th>What it does</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CREATE control (settings)</strong></td>
<td>Adds <code>control</code> to the DataWindow object (such as text, computed fields, and bitmaps). <code>Settings</code> is a list of properties and values using the format you see in exported DataWindow syntax. To create a control, you must supply enough information to define it. <code>Control</code> cannot be an OLE Object control. You cannot add an OLE object to a DataWindow using the Modify method.</td>
</tr>
<tr>
<td><strong>DESTROY [COLUMN] control</strong></td>
<td>Removes <code>control</code> from the DataWindow object. When <code>control</code> is a column, specify the keyword COLUMN to remove both the column and the column’s data from the buffer.</td>
</tr>
<tr>
<td><code>controlname.property=value</code></td>
<td>Changes the value of <code>property</code> to <code>value</code>. Properties control the location, color, size, font, and other settings for <code>controlname</code>. When <code>controlname</code> is DataWindow, you can also set properties for database access. Depending on the specific property, <code>value</code> can be: • A constant. • A quoted constant. • An expression that consists of a default value followed by a valid DataWindow expression that returns the appropriate datatype for the property. Expressions are described below.</td>
</tr>
</tbody>
</table>

**Object names** The DataWindow painter automatically gives names to all controls. In previous versions, it named only columns and column labels, and to describe and modify properties of other controls easily, you had to name them.
Expressions for Modify  When you specify an expression for a DataWindow property, the expression has the format:

\[ \text{defaultvalue} -t \text{DataWindow\_painterexpression} \]

*Defaultvalue* is a value that can be converted to the appropriate datatype for the property. It is followed by a tab (\(-t\)).

*DataWindow\_painterexpression* is an expression that can use any DataWindow painter function. The expression must also evaluate to the appropriate datatype for the property. When you are setting a column’s property, the expression is evaluated for each row in the DataWindow, which allows you to vary the display based on the data.

A typical expression uses the If function:

\[ '16777215 -t \text{If(emp\_status==''A''},255,16777215)' \]

To use that expression in a modstring, specify the following (entered as a single line):

```plaintext
modstring = "emp\_id.Color='16777215 -t
\text{If(emp\_status==''A''},255,16777215)'"
```

Not all properties accept expressions. For details on each property, see Chapter 3, “DataWindow Object Properties.”

Quotes and tildes  Because Modify’s argument is a string, which can include other strings, you need to use special syntax to specify quotation marks. To specify that a quotation mark be used within the string rather than match and end a previously opened quote, you can either specify the other style of quote (single quotes nested with double quotes) or precede the quotation mark with a tilde (\(-\)).

For another level of nesting, the string itself must specify \(-\), so you must include \(-\) (which specifies a tilde) followed by \(-\) (which specifies a quote). For example, another way to type the modstring shown above (entered as a single line) is:

```plaintext
modstring = "emp\_id.Color="16777215 -t
\text{If(emp\_status==''A''},255,16777215)-"
```

For more information about quotes and tildes, see the section on standard datatypes in the *PowerScript Reference.*
Building a modstring with variables  To use variable data in modstring, you can build the string using variables in your program. As you concatenate sections of modstring, make sure quotes are included in the string where necessary. For example, the following code builds a modstring similar to the one above, but the default color value and the two color values in the If function are calculated in the script. Notice how the single quotes around the expression are included in the first and last pieces of the string:

```sql
red_amount = Integer(sle_1.Text)
modstring = "emp_id.Color='" + &
    String(RGB(red_amount, 255, 255)) + &
    "-If(emp_status=~~'A--'," + &
    String(RGB(255, 0, 0)) + &
    "," + &
    String(RGB(red_amount, 255, 255)) + &
    ")'"
```

The following is a simpler example without the If function. You do not need quotes around the value if you are not specifying an expression. Here the String and RGB functions produce in a constant value in the resulting modstring:

```sql
modstring = "emp_id.Color=" + &
    String(RGB(red_amount, 255, 255))
```

You can set several properties with a single call to Modify by including each property setting in modstring separated by spaces. For example, assume the following is entered on a single line in the script editor:

```sql
rtn = dw_1.Modify("emp_id.Font.Italic=0
    oval_1.Background.Mode=0
    oval_1.Background.Color=255")
```

However, it is easier to understand and debug a script in which each call to Modify sets one property.

**Debugging tip**  If you build your modstring and store it in a variable that is the argument for Modify, you can look at the value of the variable in Debug mode. When Modify’s error message reports a column number, you can count the characters as you look at the compiled modstring.
Modifying a WHERE clause

For efficiency, use Modify instead of SetSQLSelect to modify a WHERE clause. Modify is faster because it does not verify the syntax and does not change the update status of the DataWindow object. However, Modify is more susceptible to user error. SetSQLSelect modifies the syntax twice (when the syntax is modified and when the retrieve executes) and affects the update status of the DataWindow object.

PowerBuilder already includes many functions for modifying a DataWindow. Before using Modify, check the list of DataWindow functions in Objects and Controls to see if a function exists for making the change. Many of these functions are listed in the See also section.

Modify is for modifying the properties of a DataWindow object and its internal controls. You can set properties of the DataWindow control that contains the object using standard dot notation. For example, to put a border on the control, specify:

```
dw_1.Border = true
```

Web DataWindow Many of the HTML generation properties that you can set with Modify can also be set with the following methods: SetBrowser, SetColumnLink, SetHTMLObjectName, SetPageSize, SetSelfLink, and SetWeight.

Examples These examples illustrate the typical uses listed in the Usage section. The examples use PowerScript. For a discussion of Modify and nested quotation marks in JavaScript, see Chapter 5, “Accessing DataWindow Object Properties in Code.”

Changing colors The effect of setting the Color property depends on the control you are modifying. To set the background color of the whole DataWindow object, use the following syntax:

```
dwcontrolname.Modify ( "DataWindow.Color="long"")
```

To set the text color of a column or a text control, use similar syntax:

```
dwcontrolname.Modify ( "controlname.Color="long"")
```

To set the background color of a column or other control, use the following syntax to set the mode and color. Make sure the mode is opaque:

```
dwcontrolname.Modify ( "controlname.Background.Mode= &
'<0 - Opaque, 1 - Transparent>'")

dwcontrolname.Modify ( "controlname.Background.Color="long"")
```
The following examples use the syntaxes shown above to set the colors of various parts of the DataWindow object.

This statement changes the background color of the DataWindow `dw_cust` to red:

```plaintext
dw_cust.Modify("DataWindow.Color = 255")
```

This statement causes the DataWindow `dw_cust` to display the text of values in the salary column in red if they exceed 90,000 and in green if they do not:

```plaintext
dw_cust.Modify( &
   "salary.Color='0-tIf(salary>90000,255,65280)'")
```

This statement nests one If function within another to provide three possible colors. The setting causes the DataWindow `dw_cust` to display the department ID in green if the ID is 200, in red if it is 100, and in black if it is neither:

```plaintext
dw_cust.Modify("dept_id.Color='0-t " &
   + "If(dept_id=200,65380,If(dept_id=100,255,0))'")
```

The following example uses a complex expression with nested If functions to set the background color of the salary column according to the salary values. Each portion of the concatenated string is shown on a separate line. See the pseudocode in the comments for an explanation of what the nested If functions do. The example also sets the background mode to opaque so that the color settings are visible.

The example includes error checking, which displays Modify's error message, if any:

```plaintext
string mod_string, err
long color1, color2, color3, default_color

err = dw_emp.Modify("salary.Background.Mode=0")
IF err <> "" THEN
   MessageBox("Status", &
      "Change to Background Mode Failed " + err)
RETURN
END IF

/* Pseudocode for mod_string:
If salary less than 10000, set the background to red.
If salary greater than or equal to 10000 but less than 20000, set the background to blue.
If salary greater than or equal to 20000 but less than 30000, set the background color to green.
Otherwise, set the background color to white, which is also the default. */
```
color1 = 255 //red
color2 = 16711680 //blue
color3 = 65280 //green
default_color = 16777215//white
mod_string = &
    "salary.Background.Color = '" &
    + String(default_color) &
    + "-tif(salary < 10000," &
    + String(color1) &
    + ",If(salary < 20000," &
    + String(color2) &
    + ",If(salary < 30000," &
    + String(color3) &
    + "," &
    + String(default_color) &
    + ")"))'"
err = dw_emp.Modify(mod_string)
IF err <> "" THEN
    MessageBox("Status", &
    "Change to Background Color Failed " + err)
    RETURN
END IF

This example sets the text color of a RadioButton column to the value of color1 (red) if the column’s value is Y; otherwise, the text is set to black. As above, each portion of the concatenated string is shown on a separate line:

    integer color1, default_color
    string mod_string, err

color1 = 255 //red
default_color = 0 //black

mod_string = "yes_or_no.Color =" &
    + String(default_color) &
    + "-tif(yes_or_no=~~'Y~~'," &
    + String(color1) &
    + "," &
    + String(default_color) &
    + ")""
err = dw_emp.Modify(mod_string)
CHAPTER 9 Methods for the DataWindow Control

IF err <> "" THEN
    MessageBox("Status", &
        "Modify to Text Color " &
        + "of yes_or_no Failed " + err)
    RETURN
END IF

Changing displayed text  To set the text of a text control, the next two examples use this syntax:

dwcontrolname.Modify ( "textcontrolname.Text='string'" )

This statement changes the text in the text control Dept_t in the DataWindow dw_cust to Dept:

dw_cust.Modify("Dept_t.Text='Dept'")

This statement sets the displayed text of dept_t in the DataWindow dw_cust to Marketing if the department ID is greater than 201; otherwise it sets the text to Finance:

dw_cust.Modify("dept_t.Text='none-t " + &
    "If(dept_id > 201,-'Marketing-',-'Finance-')'"")

Updating more than one table  An important use of Modify is to make it possible to update more than one table from one DataWindow object. The following script updates the table that was specified as updatable in the DataWindow painter; then it uses Modify to make the other joined table updatable and to specify the key column and which columns to update. This technique eliminates the need to create multiple DataWindow objects or to use embedded SQL statements to update more than one table.

In this example, the DataWindow object joins two tables: department and employee. First department is updated, with status flags not reset. Then employee is made updatable and is updated. If all succeeds, the Update command resets the flags and COMMIT commits the changes. Note that to make the script repeatable in the user’s session, you must add code to make department the updatable table again:

integer rc
string err

/* The SELECT statement for the DataWindow is:
SELECT department.dept_id, department.dept_name,
employee.emp_id, employee.emp_fname,
employee.emp_lname FROM department, employee ; */

// Update department, as set up in the DW painter
rc = dw_1.Update(true, false)

IF rc = 1 THEN
  //Turn off update for department columns.
dw_1.Modify("department_dept_name.Update = No")
dw_1.Modify("department_dept_id.Update = No")
dw_1.Modify("department_dept_id.Key = No")

  // Make employee table updatable.
dw_1.Modify( &
  "DataWindow.Table.UpdateTable = ~"employee~")

  //Turn on update for desired employee columns.
dw_1.Modify("employee_emp_id.Update = Yes")
dw_1.Modify("employee_emp_fname.Update = Yes")
dw_1.Modify("employee_emp_lname.Update = Yes")
dw_1.Modify("employee_emp_id.Key = Yes")

  //Then update the employee table.
rc = dw_1.Update()
IF rc = 1 THEN
    COMMIT USING SQLCA;
ELSE
    ROLLBACK USING SQLCA;
    MessageBox("Status", &
    + "Update of employee table failed. " &
    + "Rolling back all changes.")
END IF
ELSE
    ROLLBACK USING SQLCA;
    MessageBox("Status", &
    + "Update of department table failed. " &
    + "Rolling back changes to department.")
END IF

Adding a WHERE clause The following scripts dynamically add a WHERE clause to a DataWindow object that was created with a SELECT statement that did not include a WHERE clause. (Since this example appends a WHERE clause to the original SELECT statement, additional code would be needed to remove a where clause from the original SELECT statement if it had one.) This technique is useful when the arguments in the WHERE clause might change at execution time.
The original SELECT statement might be:

```sql
SELECT employee.emp_id, employee.l_name
FROM employee
```

Presumably, the application builds a WHERE clause based on the user’s choices. The WHERE clause might be:

```sql
WHERE emp_id > 40000
```

The script for the window’s Open event stores the original SELECT statement in `original_select`, an instance variable:

```powershell
dw_emp.SetTransObject(SQLCA)
original_select = &
    dw_emp.Describe("DataWindow.Table.Select")
```

The script for a CommandButton’s Clicked event attaches a WHERE clause stored in the instance variable `where_clause` to `original_select` and assigns it to the DataWindow’s Table.Select property:

```powershell
string rc, mod_string

mod_string = "DataWindow.Table.Select='" &
    + original_select + where_clause + "'

rc = dw_emp.Modify(mod_string)
IF rc = "" THEN
    dw_emp.Retrieve( )
ELSE
    MessageBox("Status", "Modify Failed" + rc)
END IF
```

### Quotes inserted in the DataWindow painter

For SQL Anywhere and Oracle, the DataWindow painter puts double quotes around the table and column name (for example, SELECT "EMPLOYEE"."EMP_LNAME"). Unless you have removed the quotes, the sample WHERE clause must also use these quotes. For example:

```powershell
where_clause = &
    " where ---"EMPLOYEE---"."---"SALARY---" > 40000"
```

### Query mode

Query mode provides an alternate view of a DataWindow in which the user specifies conditions for selecting data. PowerBuilder builds the WHERE clause based on the specifications. When the user exits query mode, you can retrieve data based on the modified SELECT statement.
In this example, a window that displays a DataWindow control has a menu that includes a selection called Select Data. When the user chooses it, its script displays the DataWindow control in query mode and checks the menu item. When the user chooses it again, the script turns query mode off and retrieves data based on the new WHERE clause specified by the user through query mode. The script also makes a CheckBox labeled Sort data visible, which turns query sort mode on and off.

The script for the Select Data menu item is:

```powerbuilder
string rtn

IF m_selectdata.Checked = false THEN
   // Turn on query mode so user can specify data
   rtn = dw_1.Modify("DataWindow.QueryMode=YES")

   IF rtn = "" THEN
      // If Modify succeeds, check menu to show
      // Query mode is on and display sort CheckBox
      This.Check()
      ParentWindow.cbx_sort.Show()
   ELSE
      MessageBox("Error", &
      "Can't access query mode to select data.")
   END IF
ELSE
   // Turn off Query mode and retrieve data
   // based on user's choices
   rtn = dw_1.Modify("DataWindow.QueryMode=NO")

   IF rtn = "" THEN
      // If Modify succeeds, uncheck menu to show
      // Query mode is off, hide the sort
      // CheckBox, and retrieve data
      This.UnCheck()
      ParentWindow.cbx_sort.Hide()
      dw_1.AcceptText()
      dw_1.Retrieve()
   ELSE
      MessageBox("Error", &
      "Failure exiting query mode.")
   END IF
END IF
```
A simple version of the script for Clicked event of the Sort data CheckBox follows. You could add code as shown in the Menu script above to check whether Modify succeeded:

```plaintext
IF This.Checked = true THEN
   dw_1.Modify("DataWindow.QuerySort=YES")
ELSE
   dw_1.Modify("DataWindow.QuerySort=NO")
END IF
```

For details on how you or the user specifies information in query mode, see the *PowerBuilder Users Guide*.

**DataWindow presentation styles**

You cannot use QueryMode and QuerySort with DataWindow objects that use any of the following presentation styles: N-Up, Label, Crosstab, RichText, and Graph.

*Prompt for criteria* is another way of letting the user specify retrieval criteria. You set it on a column-by-column basis. When a script retrieves data, PowerBuilder displays the Specify Retrieval Criteria window, which gives the user a chance to specify criteria for all columns that have been set.

In a script that is run before you retrieve data, for example, in the Open event of the window that displays the DataWindow control, the following settings would make the columns emp_name, emp_salary, and dept_id available in the Specify Retrieval Criteria dialog when the Retrieve method is called:

```plaintext
dw_1.Modify("emp_name.Criteria.Dialog=YES")
dw_1.Modify("emp_salary.Criteria.Dialog=YES")
dw_1.Modify("dept_id.Criteria.Dialog=YES")
```

There are other Criteria properties that affect both query mode and prompt for criteria. For details, see the Criteria DataWindow object property in Chapter 3, “DataWindow Object Properties.”

**Retrieve as needed**  In this example, the DataWindow object has been set up with Retrieve Only As Needed selected. When this is on, PowerBuilder retrieves enough rows to fill the DataWindow, displays them quickly, then waits for the user to try to display additional rows before retrieving more rows. If you want the fast initial display but do not want to leave the cursor open on the server, you can turn off Retrieve Only As Needed with Modify.
After you have determined that enough rows have been retrieved, the following code in the RetrieveRow event script changes the Retrieve.AsNeeded property, which forces the rest of the rows to be retrieved:

\texttt{dw_1.\texttt{Modify}("DataWindow.Retrieve.AsNeeded=NO")}

**Changing the data source** This example changes the data source of a DataWindow object from a SQL SELECT statement to a stored procedure. This technique works only if the result set does not change (that is, the number, type, and order of columns is the same for both sources).

When you define the DataWindow object, you must define all possible DataWindow retrieval arguments. In this example, the SELECT statement defined in the painter has three arguments, one of type string, one of type number, and one of type date. The stored procedure has two arguments, both of type string. So, in the painter, you need to define four DataWindow arguments, two of type string, one of type number, and one of type date. (Note that you do not have to use all the arguments you define.)

```powerbuilder
string rc, mod_string, name_str = "Watson"
integer dept_num = 100

// Remove the DataWindow's SELECT statement
Dw_1.\texttt{Modify}("DataWindow.Table.Select = ''")

// Set the Procedure property to your procedure
mod_string = "DataWindow.Table.Procedure = &
  '1 execute dbo.emp_arg2;1 @dept_id_arg &
  = :num_arg1, @lname_arg = :str_arg1''"
rc = dw_1.\texttt{Modify}(mod_string)

// If change is accepted, retrieve data
IF rc = "" THEN
  dw_1.Retrieve(dept_num, name_str)
ELSE
  MessageBox("Status", &
     "Change to DW Source Failed " + rc)
END IF
```
Replacing a DropDownListDataWindow object
Suppose you use `Modify` to replace one DropDownListDataWindow object with another; for example:

```plaintext
dw_parent.Modify(dept_id.ddww.name= &
                    d_ddw_empsal_by_dept )
```

PowerBuilder compares the two DataWindow objects and reuses the original result set if the number of columns and their datatypes match. The display and data value column names must exist in the data object SQL statements for both objects. If there are any differences, PowerBuilder will re-retrieve the data.

Deleting and adding controls in the DataWindow object
This statement deletes a bitmap control called logo from the DataWindow `dw_cust`:

```plaintext
dw_cust.Modify("destroy logo")
```

This statement deletes the column named `salary` from the DataWindow `dw_cust`. Note that this example includes the keyword `column`, so the column in the DataWindow and the data are both deleted:

```plaintext
dw_cust.Modify("destroy column salary")
```

This example adds a rectangle named `rect1` to the header area of the DataWindow `dw_cust` (with the value of `modstring` entered as a single line):

```plaintext
string modstring
modstring = 'create rectangle(Band=background X="206" Y="6" height="69" width="1363" brush.hatch="6" brush.color="12632256" pen.style="0" pen.width="14" pen.color="268435584" background.mode="2" background.color="-1879048064" name=rect1 )'

dw_cust.Modify(modstring)
```

These statements add a bitmap named `logo` to the header area for grouping level 1 in the DataWindow `dw_cust` (with the value of `modstring` entered as a single line):

```plaintext
string modstring
modstring = 'create bitmap(band=footer x="37" y="12" height="101" width="1509" filename="C:\PB\BEACH.BMP" border="0" name=bmp1 )'

dw_cust.Modify(modstring)
```
Syntax for creating controls
To create a control, you must provide DataWindow syntax. The easiest way to get correct syntax for all the necessary properties is to paint the control in the DataWindow painter and export the syntax to a file. Then you make any desired changes and put the syntax in your script, as shown above. This is the only way to get accurate syntax for complex controls like graphs.

Move
Description
Moves a control or object to another position relative to its parent window, or for some window objects, relative to the screen.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer *objectname*.Move ( integer x, integer y )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>objectname</em></td>
<td>A reference to an object or control you want to move</td>
</tr>
<tr>
<td>x</td>
<td>The x coordinate of the new location in PowerBuilder units</td>
</tr>
<tr>
<td>y</td>
<td>The y coordinate of the new location in PowerBuilder units</td>
</tr>
</tbody>
</table>
Return value

Returns 1 if it succeeds and –1 if an error occurs or if objectname is a maximized window.

If any argument’s value is null, Move returns null.

Usage

Inherited from system window object. For information, see Move in the PowerScript Reference.

**OLEActivate**

**Description**

Activates Object Linking and Embedding (OLE) for the specified object and sends the specified command verb to the OLE server application.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

integer dwcontrol.OLEActivate ( long row, integer column, integer verb )
integer dwcontrol.OLEActivate ( long row, string column, integer verb )

**Web ActiveX**

number dwcontrol.OLEActivate ( number 2222, number column, number verb)
number dwcontrol.OLEActivate ( number row, string column, number verb)

**Argument** | **Description**
--- | ---

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A long identifying the row location of the Database Blob control in the DataWindow object.</td>
</tr>
<tr>
<td>column</td>
<td>The column location of the Database Blob. Column can be a column number (integer) or a column name (string).</td>
</tr>
<tr>
<td>verb</td>
<td>Usually 0, but the verb is dependent on the OLE server.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, OLEActivate returns null.

**Usage**

The user can activate OLE by double-clicking an OLE blob column in a DataWindow. Use OLEActivate when you want to activate OLE in response to some other event or action—for example, when the user clicks a button.
The verb you specify determines what action occurs when the OLE server application is invoked. The default verb (0) generally means you want to edit the document. Each OLE application has its own particular set of supported verbs. To find out what verbs the application supports, consult the documentation for the application, or look for the application name in the HKEY_LOCAL_MACHINE\SOFTWARE\Classes section of the Windows registry and find its Protocol\StdFileEditingVerb key. For example, the AVIFile class has three verbs, 0, 1, and 2, for Play, Edit, and Open.

Data for an OLE application is stored in the database as a Binary/Text Large Object (blob). In SQL Anywhere, the datatype of the database column is long binary. To make the blob accessible to users, use the DataWindow painter to set up the blob column. In the painter, you add an OLE Database Blob object (called TableBlob in the DataWindow object properties) to the DataWindow object and specify the OLE server application in the Database Binary/Text Large Object window.

For setup details, see Application Techniques.

Examples

This statement activates OLE for the Database Blob control in row 5 of the salary column in DataWindow dw_emp_data. The verb is 0:

```powerbuilder
   dw_emp_data.OLEActivate(5, "salary", 0)
```

Activate in the PowerScript Reference

---

OneTrip

Description

Generates HTML syntax for the Web DataWindow after setting values that refresh the state of the server component so that it is in sync with user actions.

OneTripEx

A separate method name is provided as an alternative syntax because the Web DataWindow server component cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>
**Web DataWindow server component**

```csharp
string dwcomponent.OneTrip ( string htmlobjectname, string browser,
    string selflink, string selflinkargs, string action, string context )
```

```csharp
string dwcomponent.OneTripEx ( string htmlobjectname,
    string retrievalargs, string browser, string selflink,
    string selflinkargs, string action, string context )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component</td>
</tr>
<tr>
<td>htmlobjectname</td>
<td>A string specifying a name used in generated code for the Web DataWindow client control, page parameters, and client side events. You must specify a unique object name when there is more than one Web DataWindow on a Web page.</td>
</tr>
<tr>
<td>retrievalargs</td>
<td>A string that contains the values of the retrieval arguments expected by the DataWindow object associated with the server component (see Usage note).</td>
</tr>
<tr>
<td>browser</td>
<td>A string identifying the browser and version. The value should match the browser information passed to the Web server in the HTTP header. The corresponding server variable is HTTP_USER_AGENT. For information on recognized browsers, see HTMLGen.property.</td>
</tr>
<tr>
<td>selflink</td>
<td>The URL for the current page. It cannot include parameters. Parameters from selflinkargs may be added when HTML is generated. The server component uses SelfLink to generate URLs for navigation buttons that obtain additional rows from the result set. Sets the value of the HTMLGen.SelfLink property for the DataWindow object associated with the server component.</td>
</tr>
<tr>
<td>selflinkargs</td>
<td>A string in the form: argname='exp'{ argname = 'exp'} ... Argname is an argument passed to the server. Exp is a DataWindow expression whose value is a string. The DataWindow in the server component evaluates it, converts it using URL encoding, and includes in the selflinkargs string. Sets the value of the HTMLGen.SelfLinkArgs property for the DataWindow object associated with the server component.</td>
</tr>
</tbody>
</table>
Return value

Returns the generated HTML if it succeeds and an error message if any of the requested settings fails.

Usage

OneTrip and OneTripEx perform the tasks of SetSelfLink, SetBrowser, Retrieve, SetAction, and Generate in a single method. They are meant to be used with an EAServer component that has been previously configured with a DataWindow definition and transaction information. Using OneTrip produces maximum performance for the Web DataWindow client while allowing the server component to remain stateless.

Use OneTripEx instead of OneTrip if you need to specify retrieval arguments. The retrievalargs string in the OneTripEx syntax has the format:

value1 \n value2 \n value3... \n value16

The values of the retrieval arguments must be separated by newline characters (\n) and individual values cannot contain newline characters as part of the value. The Web DataWindow supports up to 16 retrieval arguments.

You can specify an array for the value of a retrieval argument by separating the array values with a tab character (\t). For example, if the DataWindow expected an array for the second retrieval argument, the syntax would be:

value1 \n value2\t value2b \t value2c \n value3...

If the script gets the values for the retrieval arguments from page parameters, you must also specify the retrieval arguments as selflinkargs expressions, so that the values will be available as page parameters when the page is reloaded.

The evaluated selflinkargs expressions are included in the generated HTML as hidden fields and are available to server-side scripts as page parameters. You can use the arguments to supply information that the server component needs to render additional pages of the result set, such as retrieval arguments. Selflinkargs can also be used to keep login information or other data available that was passed in the original call to the page.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>A string describing an action associated with a button click or method call in a Web DataWindow client control on a Web page. The value of action is stored in a page parameter called htmlobjectname_action.</td>
</tr>
<tr>
<td>context</td>
<td>A string describing the context of action in the Web DataWindow client control. The string is generated by a Web DataWindow script and the value is stored in a page parameter called htmlobjectname_context. The format is not documented and subject to change.</td>
</tr>
</tbody>
</table>
For information on quotation marks and other formatting for the expression, see the SetSelfLink method. For information about using the Web DataWindow, see the *DataWindow Programmers Guide*.

**Examples**

This Web Target server-side script uses OneTripEx to get generated HTML. The DataWindow object expects two retrieval arguments, an employee ID and a salary:

```javascript
function GetParam( envparam ) {
   if( exists(document.value[envparam] ) ) {
      return document.value[envparam];
   }
   return "";
};

// Create component on server

// Get information about user's latest button click
var action = psDocument.GetParam("dwMine_action");
var context = psDocument.GetParam("dwMine_context");

// Get browser and hyperlinking information
var browser = psDocument.GetEnv("HTTP_USER_AGENT");
var selfLink = psDocument.GetEnv("SCRIPT_NAME");

// Get retrieval arguments from page parameters

// Set up page parameters for reloaded page
linkargs = "arg_empid ='" + psDocument.GetParam("arg_empid") + "\""
   + "arg_salary= '" + psDocument.GetParam("arg_salary") + "\"";

// Include the generated HTML in the Web page
psDocument.Write(dwMine.OneTripEx("dwMine", args, OneTripEx("dwMine", args, browser, selfLink, linkargs, action, context) ));
```

Paste

Description
Inserts (pastes) the contents of the clipboard into the specified control. If no text is selected in the control, the text on the clipboard is pasted at the insertion point. If text is selected, Paste replaces the selected text with the text on the clipboard.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

long *dwcontrol*.Paste ( )

**Web ActiveX**

number *dwcontrol*.Paste ( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>dwcontrol</em></td>
<td>A reference to a DataWindow control. Text is pasted into the edit control over the current row and column.</td>
</tr>
</tbody>
</table>

Return value
Returns the number of characters that were pasted into the edit control for *dwcontrol*. If nothing has been cut or copied (the clipboard is empty), Paste does not change the contents of the edit control and returns 0. If the clipboard contains nontext data (for example, a bitmap or OLE object) and the control cannot accept that data, Paste does not change the contents and returns 0.

If *dwcontrol* is null, in PowerBuilder and JavaScript the method returns null.

Usage
The text is pasted into the edit control over the current row and column. If the clipboard contains more text that is allowed for that column, the text is truncated. If the clipboard text does not match the column’s datatype, all the text is truncated, so that any selected text is replaced with an empty string.

To insert a specific string in *dwcontrol* or to replace selected text with a specific string, use the ReplaceText method.

**PowerBuilder environment**
For use with other PowerBuilder controls, see Paste in the *PowerScript Reference*.  

# PowerBuilder

748
Examples

If the clipboard contains “Proposal good for 90 days” and no text is selected in the edit control of \texttt{dw\_rpt}, this statement pastes “Proposal good for 90 days” at the insertion point in the edit control and returns 25:

\texttt{dw\_rpt.Paste()}

If the clipboard contains the string “Final Edition”, the edit control in \texttt{dw\_rpt} contains “This is a Preliminary Draft”, and the text in edit control is selected, this statement deletes “This is a Preliminary Draft”, replaces it with “Final Edition”, and returns 13:

\texttt{dw\_rpt.Paste()}

Cut
ReplaceText

\section*{PasteRTF}

\textbf{Description}

Pastes rich text data from a string into a DataWindow control or DataStore object.

\textbf{Applies to}

\begin{tabular}{|c|c|}
\hline
DataWindow type & Method applies to \\
\hline
PowerBuilder & DataWindow control, DataStore object \\
\hline
\end{tabular}

\textbf{Syntax}

\texttt{PowerBuilder long \texttt{rtename.PasteRTF ( string richtextstring, \{ Band band\}})}

\begin{tabular}{|l|l|}
\hline
Argument & Description \\
\hline
\texttt{rtename} & A reference to a DataWindow control or DataStore object. The DataWindow object in the DataWindow control or DataStore must be a RichTextEdit DataWindow. \\
\hline
\texttt{richtextstring} & A string whose value is data with rich text formatting. \\
\hline
\texttt{band} & A value specifying the band into which the rich text data is pasted. Valid values for this enumerated datatype are listed in Chapter 6, “DataWindow Constants”. The default is the band that contains the insertion point. \\
\hline
\texttt{band} (optional) & \\
\hline
\end{tabular}

\textbf{Return value}

Returns -1 if an error occurs. If \texttt{richtextstring} is null, \texttt{PasteRTF} returns null.
A DataWindow in the RTE presentation style has only three bands. There are no summary or trailer bands and there are no group headers and footers.

**PowerBuilder RichText Edit control**
You can use the same syntax with any PowerBuilder RichTextEdit control. See PasteRTF in the *PowerScript Reference*.

This statement pastes rich text in the string ls_richtext into the header of the RichTextEdit rte_message:

```
string ls_richtext
rte_message.PasteRTF(ls_richtext, Header!)
```

See also
CopyRTF

**PointerX**

**Description**
Determine the distance of the pointer from the left edge of the specified object.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

```
integer objectname.PointerX ()
```

**Argument**

<table>
<thead>
<tr>
<th>objectname</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectname</td>
<td>The name of the control or window for which you want the pointer’s distance from the left edge. If you do not specify objectname, PointerX reports the distance from the left edge of the current sheet or window.</td>
</tr>
</tbody>
</table>

**Return value**
Returns the pointer’s distance from the left edge of objectname in PowerBuilder units if it succeeds and –1 if an error occurs.

**Usage**
Inherited from DragObject. For information, see PointerX in the *PowerScript Reference*. 
**PointerY**

**Description**
Determines the distance of the pointer from the top of the specified object.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

```
integer objectname.PointerY ( )
```

**Argument**
```
objectname
```

**Description**

- The name of the control or window for which you want the pointer’s distance from the top. If you do not specify `objectname`, `PointerY` reports the distance from the top of the current sheet or window.

**Return value**

Returns the pointer’s distance from the top of `objectname` in PowerBuilder units if it succeeds and -1 if an error occurs.

- If `objectname` is null, `PointerY` returns null.

**Usage**

Inherited from DragObject. For information, see `PointerY` in the *PowerScript Reference*.

---

**Position**

Reports the position of the insertion point in a DataWindow.

**To report**

<table>
<thead>
<tr>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax 1</td>
</tr>
<tr>
<td>Syntax 2</td>
</tr>
</tbody>
</table>

- The position of the insertion point in a DataWindow that does not have a RichTextEdit presentation style
- The position of the insertion point or the start and end of selected text in a DataWindow whose object has the RichTextEdit presentation style
**Position**

**Syntax 1**

**For DataWindows with standard presentation styles**

**Description**

Determines the position of the insertion point in an edit control.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

long editname.Position()

**Web ActiveX**

number editname.Position()

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>editname</td>
<td>A reference to a DataWindow control in which you want to find the location of the insertion point</td>
</tr>
</tbody>
</table>

**Return value**

Returns the location of the insertion point in editname if it succeeds and –1 if an error occurs. If editname is null, Position returns null.

**Usage**

Position reports the position number of the character immediately following the insertion point. For example, Position returns 1 if the cursor is at the beginning of editname. If text is selected in editname, Position reports the number of the first character of the selected text.

Position reports the insertion point’s position in the edit control over the current row and column.

**PowerBuilder environment**

For use with other PowerBuilder controls, see Position in the PowerScript Reference.

**Examples**

If mle_EmpAddress contains Boston Street, the cursor is immediately after the n in Boston, and no text is selected, this statement returns 7:

mle_EmpAddress.Position()

If mle_EmpAddress contains Boston Street and Street is selected, this statement returns 8 (the position of the S in Street):

mle_EmpAddress.Position()

SelectedLine
SelectedStart

---

752 PowerBuilder
Syntax 2  
For DataWindows with RichTextEdit presentation styles

Description
Determines the line and column position of the insertion point or the start and end of selected text in a RichTextEdit control.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

```powershell
band rtename.Position ( long fromline, long fromchar {, long toline, long tochar })
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtename</td>
<td>A reference to a DataWindow control. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.</td>
</tr>
<tr>
<td>fromline</td>
<td>A variable in which you want to save the number of the line where the insertion point or the start of the selection is.</td>
</tr>
<tr>
<td>fromchar</td>
<td>A variable in which you want to save the number in the line of the first character in the selection or after the insertion point.</td>
</tr>
<tr>
<td>toline</td>
<td>A variable in which you want to save the number of the line where the selection ends. (optional)</td>
</tr>
<tr>
<td>tochar</td>
<td>A variable in which you want to save the number in the line of the character before which the selection ends. (optional)</td>
</tr>
</tbody>
</table>

Return value
Returns the band containing the selection or insertion point. The returned value is a value of the Band enumerated datatype (Detail!, Header!, or Footer!).

Usage
Position reports the position of the insertion point if you omit the `toline` and `tochar` arguments. If text is selected, the insertion point can be at the beginning or the end of the selection. For example, if the user dragged down to select text, the insertion point is at the end.

If there is a selection, a character argument can be set to 0 to indicate that the selection begins or ends at the start of a line, with nothing else selected on that line. When the user drags up, the selection can begin at the start of a line and `fromchar` is set to 0. When the user drags down, the selection can end at the beginning of a line and `tochar` is set to 0.
Selection or insertion point  To find out whether there is a selection or just an insertion point, specify all four arguments. If tolino and tochar are set to 0, then there is no selection, only an insertion point. If there is a selection and you want the position of the insertion point, you will have to call Position again with only two arguments. This difference is described next.

The position of the insertion point and end of selection can differ  When reporting the position of selected text, the positions are inclusive—Position reports the first line and character and the last line and character that are selected. When reporting the position of the insertion point, Position identifies the character just after the insertion point. Therefore, if text is selected and the insertion point is at the end, the values for the insertion point and the end of the selection differ.

To illustrate, suppose the first four characters in line 1 are selected and the insertion point is at the end. If you request the position of the insertion point:

```null
rte_1.Position(ll_line, ll_char)
```

Then:

* ll_line is set to 1
* ll_char is set to 5, the character following the insertion point

If you request the position of the selection:

```null
rte_1.Position(ll_startline, ll_startchar, & ll_endline, ll_endchar)
```

* ll_startline and ll_startchar are both set to 1
* ll_endline is 1 and ll_endchar is set to 4, the last character in the selection

Passing values to SelectText  Because values obtained with Position provide more information than simply a selection range, you cannot pass the values directly to SelectText. In particular, 0 is not a valid character position when selecting text, although it is meaningful in describing the selection.

Examples  This example calls Position to get the band and the line and column values for the beginning and end of the selection. The values are converted to strings and displayed in the StaticText st_status:

```null
integer li_rtn
long ll_startline, ll_startchar
long ll_endline, ll_endchar
string ls_s, ls_band
band l_band
```
// Get the band and start and end of the selection
l_band = rte_1.Position(ll_startline, ll_startchar, &
   ll_endline, ll_endchar)

// Convert position values to strings
ls_s = "Start line/char: " + String(ll_startline) &
   + ", " + String(ll_startchar)
ls_s = ls_s + " End line/char: " &
   + String(ll_endline) + ", " + String(ll_endchar)

// Convert Band datatype to string
CHOOSE CASE l_band
   CASE Detail!
      ls_band = " Detail"
   CASE Header!
      ls_band = " Header"
   CASE Footer!
      ls_band = " Footer"
   CASE ELSE
      ls_band = " No band"
END CHOOSE
ls_s = ls_s + ls_band

// Display the information
st_status.Text = ls_s

This example extends the current selection down 1 line. It takes into account
whether there is an insertion point or a selection, whether the insertion point is
at the beginning or end of the selection, and whether the selection ends at the
beginning of a line:

integer rtn
long l1, c1, l2, c2, linsert, cinsert
long l1select, c1select, l2select, c2select

// Get selection start and end
rte_1.Position(l1, c1, l2, c2)
// Get insertion point
rte_1.Position(linsert, cinsert)

IF l2 = 0 and c2 = 0 THEN //insertion point
   l1select = linsert
   c1select = cinsert
   l2select = l1select + 1 // Add 1 to end line
   c2select = c1select
ELSEIF l2 > l1 THEN // Selection, ins pt at end
  IF c2 = 0 THEN // End of selection (ins pt)
    // at beginning of a line (char 0)
    c2 = 999 // Change to end of prev line
    l2 = l2 - 1
  END IF

  l1select = l1
  c1select = c1
  l2select = l2 + 1 // Add 1 to end line
  c2select = c2

ELSEIF l2 < l1 THEN // selection, ins pt at start
  IF c1 = 0 THEN // End of selection (not ins pt)
    // at beginning of a line
    c1 = 999 // Change to end of prev line
    l1 = l1 - 1
  END IF

  l1select = l2
  c1select = c2
  l2select = l1 + 1 // Add 1 to end line
  // (start of selection)
  c2select = c1

ELSE // l1 = l2, selection on one line
  l1select = l1
  l2select = l2 + 1 // Add 1 to line
  IF c1 < c2 THEN // ins pt at end
    c1select = c1
    c2select = c2
  ELSE // c1 > c2, ins pt at start
    c1select = c2
    c2select = c1
  END IF
END IF

// Select the extended selection
rtn = rte_1.SelectText( l1select, c1select, &
  l2select, c2select )

For an example of selecting each word in a RichTextEdit control, see
SelectTextWord.

CHAPTER 9   Methods for the DataWindow Control

PostEvent

Description

Adds an event to the end of the event queue of an object.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```plaintext
boolean objectname.PostEvent ( TrigEvent event, { long word, long long } )
boolean objectname.PostEvent ( TrigEvent event, { long word, string long } )
```

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectname</td>
<td>The name of any PowerBuilder object or control (except an application) that has events associated with it.</td>
</tr>
<tr>
<td>event</td>
<td>A value of the TrigEvent enumerated datatype that identifies a PowerBuilder event (for example, Clicked!, Modified!, or DoubleClicked!) or a string whose value is the name of an event. The event must be a valid event for objectname and a script must exist for the event in objectname.</td>
</tr>
<tr>
<td>word (optional)</td>
<td>A value to be stored in the WordParm property of the system’s Message object. If you want to specify a value for long, but not for word, enter 0. (For cross-platform compatibility, WordParm and LongParm are both longs.)</td>
</tr>
<tr>
<td>long (optional)</td>
<td>A value that you want to store in the LongParm property of the system’s Message object. When you specify a string, a pointer to the string is stored in the LongParm property, which you can access with the String function (see Usage).</td>
</tr>
</tbody>
</table>

Return value

Returns true if it is successful and false if the event is not a valid event for objectname or no script exists for the event in objectname.

If any argument’s value is null, PostEvent returns null.

Usage

Inherited from PowerObject. For information, see PostEvent in the PowerScript Reference.
Print

Sends data to the current printer (or spooler, if the user has a spooler set up). There are two syntaxes that you can use with DataWindows:

<table>
<thead>
<tr>
<th>To</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Send the contents of a DataWindow control or DataStore to the printer as a print job.</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>Include a visual object, such as a window or a graph control, in a print job. For the PowerBuilder environment only. For a description of PowerBuilder system print commands, see the PowerScript Reference.</td>
<td>Syntax 2</td>
</tr>
</tbody>
</table>

Syntax 1

**For printing a single DataWindow or DataStore**

Sends the contents of a DataWindow control or DataStore object to the printer as a print job.

**Description**

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powershell
integer dwcontrol.Print ( { boolean canceldialog , showprintdialog } )
```

**Web ActiveX**

```powershell
number dwcontrol.Print ( boolean canceldialog )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the DataWindow control, DataStore, or child DataWindow that contains the information to be printed.</td>
</tr>
</tbody>
</table>
| canceldialog (optional) | A boolean value indicating whether you want to display a nonmodal dialog that allows the user to cancel printing. Values are:  
- True – (Default) Display the dialog.  
- false – Do not display the dialog. |

**Working with DataStore objects**

When working with DataStores, the `canceldialog` argument must always be set to `false`. 
CHAPTER 9  Methods for the DataWindow Control

Return value
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, Print returns null.

Usage
Printed output uses the same fonts and layout that appear on screen for the DataWindow object.
When the DataWindow object’s presentation style is RichTextEdit, each row begins a new page in the printed output.

PowerBuilder environment
PowerBuilder manages print jobs by opening the job, sending data, and closing the job. When you use Syntax 1, print job management happens automatically. You do not need to use the PrintOpen and PrintClose functions.

Use Syntax 1 to print the contents of a DataWindow object. The Print method prints all the rows that have been retrieved. To print several DataWindows as a single job, do not use Print. Instead, open the print job with PrintOpen, call the PowerScript system function PrintDataWindow for each DataWindow, and close the job.

Events for DataWindow printing
When you use Print for DataWindow controls or DataStores, it triggers a PrintStart event just before any data is sent to the printer (or spooler), a PrintPage event for each page break, and a PrintEnd event when printing is complete.

The PrintPage event has return codes that let you control whether the page about to be formatted is printed. You can skip the upcoming page by returning a value of 1 in the PrintPage event.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showprintdialog (optional)</td>
<td>A boolean value indicating whether you want to display the system Print dialog box. Values are:</td>
</tr>
<tr>
<td></td>
<td>True – Display the dialog box</td>
</tr>
<tr>
<td></td>
<td>false – (default) Do not display the dialog box</td>
</tr>
</tbody>
</table>

Working with DataStore objects
When working with DataStores, the showprintdialog argument must always be set to false.
**Examples**

The following statements are equivalent. Each sends the contents of `dw_employee` to the current printer. The Cancel dialog box displays, allowing the user to cancel the printing, but the Print dialog box does not:

- `dw_employee.Print()`
- `dw_employee.Print(true)`
- `dw_employee.Print(true, false)`

This statement sends the contents of `dw_employee` to the current printer. The Print dialog box displays but the Cancel dialog box does not:

- `dw_employee.Print(false, true)`

See also

PrintDataWindow in the *PowerScript Reference*

**Syntax 2**

**For printing a visual object in a print job**

Includes a visual object, such as a window or a graph control, in a print job that you have started with the `PrintOpen` function.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**PowerBuilder**

```powerbuilder
def objectname.Print (long printjobnumber, integer x, integer y {, integer width, integer height})
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>objectname</code></td>
<td>The name of the object that you want to print. The object must either be a window or an object whose ancestor type is DragObject, which includes all the controls that you can place in a window.</td>
</tr>
<tr>
<td><code>printjobnumber</code></td>
<td>The number the <code>PrintOpen</code> function assigns to the print job</td>
</tr>
<tr>
<td><code>x</code></td>
<td>An integer whose value is the x coordinate on the page of the left corner of the object, in thousandths of an inch.</td>
</tr>
<tr>
<td><code>y</code></td>
<td>An integer whose value is the y coordinate on the page of the left corner of the object, in thousandths of an inch.</td>
</tr>
<tr>
<td><code>width</code> (optional)</td>
<td>An integer specifying the printed width of the object in thousandths of an inch. If omitted, PowerBuilder uses the object’s original width.</td>
</tr>
<tr>
<td><code>height</code> (optional)</td>
<td>An integer specifying the printed height of the object in thousandths of an inch. If omitted, PowerBuilder uses the object’s original height.</td>
</tr>
</tbody>
</table>
Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, Print returns null.

Usage

PowerBuilder manages print jobs by opening the job, sending data, and closing the job. When you use Syntax 2, you must call the PrintOpen function and the PrintClose or PrintCancel functions yourself to manage the process. For more information, see the PowerScript Reference.

Print area and margins

The print area is the physical page size minus any margins in the printer itself. Depending on the printer, you may be able to change margins using PrintSend and printer-defined escape sequences.

Examples

This example prints the CommandButton cb_close in its original size at location 500, 1000:

```
long Job
Job = PrintOpen( )
cb_close.Print(Job, 500,1000)
PrintClose(Job)
```

This example opens a print job, which defines a new page, then prints a title using the third syntax of Print. Then it uses this syntax of Print to print a graph on the first page and a window on the second page:

```
long Job
Job = PrintOpen( )
Print(Job, "Report of Year-to-Date Sales")
gr_sales1.Print(Job, 1000,PrintY(Job)+500, &
                  6000,4500)
PrintPage(Job)
w_sales.Print(Job, 1000,500, 6000,4500)
PrintClose(Job)
```

See also

Print in the PowerScript Reference
PrintCancel
PrintClose in the PowerScript Reference
PrintOpen in the PowerScript Reference
PrintScreen in the PowerScript Reference
PrintCancel

Cancels printing and deletes the spool file, if any. There are two syntaxes.

<table>
<thead>
<tr>
<th>To</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cancel printing of a DataWindow or DataStore printed with the Print function.</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>Cancel a print job that you began with the PrintOpen function. For the PowerBuilder environment only.</td>
<td>Syntax 2</td>
</tr>
</tbody>
</table>

Syntax 1

**For DataWindows and DataStores**

Cancels the printing of a DataWindow or DataStore that was printed using Syntax 1 of Print.

**Description**

To Use

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

integer dwcontrol.PrintCancel ()

**Web ActiveX**

number dwcontrol.PrintCancel ()

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore object, or child DataWindow.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and −1 if an error occurs. If dwcontrol is null, PrintCancel returns null.

**Usage**

PrintCancel cancels the printing of the specified DataWindow or DataStore by deleting the spool file, if any, and closing the job.
When you use Print for DataWindow controls or DataStores, it triggers a PrintStart event just before any data is sent to the printer (or spooler), a PrintPage event for each page break, and a PrintEnd event when printing is complete. You can use PrintCancel in the PrintStart or PrintPage event to cancel printing.

**Examples**

This statement sends the contents of the DataWindow dw_employee to the current printer without displaying the Cancel dialog:

```powerbuilder
dw_Employee.Print(FALSE)
```

This statement in the PrintStart event cancels printing:

```powerbuilder
dw_employee.PrintCancel()
```

**Syntax 2**

**For canceling a print job**

**Description**

Cancels printing of a print job that you opened with the PrintOpen function. The print job is identified by the number returned by PrintOpen.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

```powerbuilder
integer PrintCancel ( long printjobnumber )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>printjobnumber</td>
<td>The number the PrintOpen function assigned to the print job.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If printjobnumber is null, PrintCancel returns null.

**Usage**

PrintCancel cancels the specified print job by deleting the spool file, if any, and closing the job. Because PrintCancel closes the print job, do not call the PrintClose function after you call PrintCancel.
In this example, a script for a Print button opens a print job and then opens a window with a cancel button. If the user clicks on the cancel button, its script sets a global variable that indicates that the user wants to cancel the job. After each printing command in the Print button’s script, the code checks the global variable and cancels the job if its value is true.

The definition of the global variable is:

```powerbuilder
boolean gb_printcancel
```

The script for the Print button is:

```powerbuilder
long job, li

gb_printcancel = false
job = PrintOpen("Test Page Breaks")
IF job < 1 THEN
   MessageBox("Error", "Can't open a print job.")
   RETURN
END IF

Open(w_printcancel)

PrintBitmap(Job, "d:\PB\bitmap1.bmp", 5, 10, 0, 0)
IF gb_printcancel = true THEN
   PrintCancel(job)
   RETURN
END IF

... // Additional printing commands,
... // including checking gb_printcancel

PrintClose(job)
Close(w_printcancel)
```

The script for the cancel button in the second window is:

```powerbuilder
gb_printcancel = true
Close(w_printcancel)
```

See also

- Print
- PrintCancel in the PowerScript Reference
- PrintClose in the PowerScript Reference
- PrintOpen in the PowerScript Reference
ReplaceText

Description
Replaces selected text in the edit control for the current row and column with a specified string.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

`long editname.ReplaceText ( string string )`

Web ActiveX

`number editname.ReplaceText ( string string )`

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>editname</td>
<td>A reference to a DataWindow control</td>
</tr>
<tr>
<td>string</td>
<td>The string that replaces the selected text</td>
</tr>
</tbody>
</table>

Return value
Returns the number of characters in `string` and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage
If there is no selection, `ReplaceText` inserts the replacement text at the cursor position.

To use the contents of the clipboard as the replacement text, call the `Paste` method instead of `ReplaceText`.

PowerBuilder environment
For use with other PowerBuilder controls, see ReplaceText in the PowerScript Reference.

Examples

If the DataWindow edit control contains “Offer Good for 3 Months” and the selected text is “3 Months”, this statement replaces “3 Months” with “60 Days” and returns 7. The resulting text in the edit control is “Offer Good for 60 Days”:

```
dw_salesoffer.ReplaceText("60 Days")
```

If there is no selected text, this statement inserts “New product” at the cursor position in the edit control for `dw_products`:

```
dw_products.ReplaceText("New product")
```
ReselectRow

Description
Accesses the database to retrieve values for all columns that can be updated and refreshes all timestamp columns in a row in a DataWindow control or DataStore. The values from the database are redisplayed in the row.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer *dwcontrol*.ReselectRow ( long *row*)

**Web DataWindow server component**

short *dwcontrol*.ReselectRow ( long *row*)

**Web ActiveX**

number *dwcontrol*.ReselectRow ( number *row*)

Argument | Description
----------|--------------------------------------------------
*dwcontrol* | A reference to the DataWindow control, DataStore, or child DataWindow in which you want to reselect a row.
*row* | A value identifying the row to reselect.

Return value
Returns 1 if it is successful and –1 if the row cannot be reselected (for example, the DataWindow object cannot be updated or the row was deleted by another user).

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage
ReselectRow is supported for SQLSelect DataWindows. Use ReselectRow to discard values the user changed and replace them with values from the database after an update fails (due to a concurrent access error, for example).
About timestamp support
Timestamp support is not available in all DBMSs. For information on
timestamp columns, see the documentation for your DBMS.

Examples
This statement reselects row 5 in the DataWindow control dw_emp:

   dw_emp.ReselectRow(5)

This statement reselects the clicked row if the update is not successful:

   IF dw_emp.Update( ) < 0 THEN
       dw_emp.ReselectRow(dw_emp.GetClickedRow())
   END IF

See also
GetClickedRow
SelectRow
Update

Reset
Description
Clears all the data from a DataWindow control or DataStore object.

For the syntax to use for deleting graphs within a DataWindow object that have
an external data source, see Reset on page 960. For the syntax to use with other
PowerBuilder controls, see Reset in the PowerScript Reference.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

   integer dwcontrol.Reset( )

Web DataWindow server component

   short dwcontrol.Reset( )
### Reset

#### Web ActiveX

```
number dwcontrol.Reset( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. The return value is usually not used.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

`Reset` is not the same as deleting rows from the DataWindow object or child DataWindow. `Reset` affects the application only, not the database. If you delete rows and then call the `Update` method, the rows are deleted from the database table associated with the DataWindow object. If you call `Reset` and then call `Update`, no changes are made to the table.

**PowerBuilder environment**

If you call `Reset` when the Retrieve As Needed option is set, `Reset` will clear the rows that have been retrieved. However, because Retrieve As Needed is on, the DataWindow immediately retrieves the next set of rows.

To prevent the rows from being retrieved, call `DBCancel` before calling `Reset`. If all the rows have been retrieved (the cursor has been closed and the RetrieveEnd event has occurred), then when `Reset` clears the DataWindow, it stays empty.

**Examples**

This statement completely clears the contents of `dw_employee`:

```
dw_employee.Reset( )
```

In a DataWindow whose Retrieve As Needed option is on, this example cancels the retrieval before resetting the DataWindow:

```
dw_employee.DBCancel( )

dw_employee.Reset( )
```

**See also**

DeleteRow
ResetInk

Description
Clears ink from an InkPicture control in a DataWindow.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

```
integer dwcontrol.ResetInk ( string name, long rownumber )
```

Argument | Description
---------|-------------
```
dwcontrol
name
rownumber
```

A reference to a DataWindow control.
The name of the InkPicture control from which you want to clear the picture.
The number of the row that contains the picture to be cleared. To clear all rows, set `rownumber` to 0.

Return value
Integer. Returns 1 for success and –1 for failure.

Usage
Use the `ResetInk` function to clear the ink from an InkPicture control.

Examples
The following example clears the ink in an InkPicture control in row 3 of a DataWindow object:

```
int li_return
li_return = dw_1.ResetInk(inkpic_1, 3)
```

See also
SaveInk
SaveInkPic

ResetTransObject

Description
 Stops a DataWindow control or DataStore from using the programmer-specified transaction object that is currently in effect through a call to the SetTransObject method. After you call the ResetTransObject method, the DataWindow control or DataStore uses its internal transaction object.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

ResetTransObject

Syntax

**PowerBuilder**

- integer *dwcontrol*.ResetTransObject()

**Web ActiveX**

- number *dwcontrol*.ResetTransObject()

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>dwcontrol</em></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and –1 if an error occurs. The return value is usually not used.

If *dwcontrol* is null, the method returns null.

Usage

If you reset the transaction object and SetTrans has never been called to set the values in the internal transaction object, call SetTrans to set them or SetTransObject to establish a new programmer-specified transaction object.

*ResetTransObject* is almost never used because programmer-specified and internal transaction objects in one application are generally not used together. Programmer-specified transaction objects, specified with SetTransObject, provide better application performance. To change the programmer-specified transaction object, simply call SetTransObject again.

Examples

This statement stops *dw_employee* from using programmer-specified transaction objects:

```
dw_employee.ResetTransObject();
```

See also

GetTrans
SetTrans
SetTransObject
CHAPTER 9  Methods for the DataWindow Control

ResetUpdate

Description
Clears the update flags in the primary and filter buffers and empties the delete buffer of a DataWindow or DataStore.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
integer dwcontrol.ResetUpdate ( )
```

**Web DataWindow server component**

```
short dwcontrol.ResetUpdate ( )
```

**Web ActiveX**

```\nnumber dwcontrol.ResetUpdate ( )
```

Argument | Description
----------|--------------------------------------------------
`dwcontrol` | The name of the DataWindow control, DataStore, or child DataWindow in which you want to reset the update flags

Return value
Returns 1 if it succeeds and –1 if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

Usage

When a row is changed, inserted, or deleted, its update flag is set, marking it for update. By default the `Update` method turns these flags off. If you want to coordinate updates of more than one DataWindow or DataStore, however, you can prevent `Update` from clearing the flags. Then, after you verify that all the updates succeeded, you can call `ResetUpdate` for each DataWindow to clear the flags. If one of the updates failed, you can keep the update flags, prompt the user to fix the problem, and try the updates again.

You can find out which rows are marked for update with the `GetItemStatus` method. If a row is in the delete buffer or if it is in the primary or filter buffer and has NewModified! or DataModified! status, its update flag is set. After update flags are cleared, all rows have the status NotModified! or New! and the delete buffer is empty.
Examples

These statements coordinate the update of two DataWindow objects:

```powerbuilder
int rtncode
CONNECT USING SQLCA;
dw_cust.SetTransObject(SQLCA)
dw_sales.SetTransObject(SQLCA)

rtncode = dw_cust.Update(true, false)
IF rtncode = 1 THEN
    rtncode = dw_sales.Update(true, false)
    IF rtncode = 1 THEN
        dw_cust.ResetUpdate() // Both updates are OK
        dw_sales.ResetUpdate() // Clear update flags
        COMMIT USING SQLCA; // Commit them
    ELSE
        ROLLBACK USING SQLCA; // 2nd update failed
    END IF
END IF
```

See also Update

---

**Resize**

**Description**
Resizes an object or control by setting its Width and Height properties and then redraws the object.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
integer objectname.Resize (integer width, integer height )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectname</td>
<td>A reference to the object or control you want to resize</td>
</tr>
<tr>
<td>width</td>
<td>The new width in PowerBuilder units</td>
</tr>
<tr>
<td>height</td>
<td>The new height in PowerBuilder units</td>
</tr>
</tbody>
</table>

**Return value**
Returns 1 if it succeeds and –1 if an error occurs or if `objectname` is a minimized or maximized window.
CHAPTER 9  Methods for the DataWindow Control

Usage

You cannot use Resize for a child DataWindow.

Use with other PowerBuilder objects and controls

Resize does not resize a minimized or maximized sheet or window. If the window is minimized or maximized, Resize returns –1.

For use with other PowerBuilder controls, see Resize in the PowerScript Reference.

Examples

This statement changes the Width and Height properties of gb_box1 and redraws gb_box1 with the new properties:

\[ \text{gb\_box1.\texttt{Resize}(100, 150)} \]

This statement doubles the width and height of the picture control p_1:

\[ \text{p\_1.\texttt{Resize}(p\_1.Width*2, p\_1.Height*2)} \]

Retrieve

Description

Retrieves rows from the database for a DataWindow control or DataStore. If arguments are included, the argument values are used for the retrieval arguments in the SQL SELECT statement for the DataWindow object or child DataWindow.

RetrieveEx

A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods. The RetrieveEx method for the server component takes a string of values for an argument. The DataWindow Web ActiveX control can also use a RetrieveEx method, but it uses an array for an argument instead of a string of values.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

\[ \text{long \texttt{dwcontrol.Retrieve} (\{ \text{any argument, any argument} \ldots \})} \]
Retrieve

Web DataWindow client control

number dwcontrol.Retrieve ( )

Web DataWindow server component

int dwcontrol.Retrieve ( )
int dwcontrol.RetrieveEx ( string argument )

Web ActiveX

number dwcontrol.Retrieve ( { variant argument, variant argument . . . } )
number dwcontrol.RetrieveEx ( variant argument [ ] )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>argument (optional with Retrieve, required with RetrieveEx)</td>
<td>One or more values that you want to use as retrieval arguments in the SQL SELECT statement defined in dwcontrol. This must be a single string containing one or more values for the Web DataWindow server component (see Usage note). It must be a single array of values for the Web ActiveX control.</td>
</tr>
</tbody>
</table>

Return value

Returns the number of rows displayed (that is, rows in the primary buffer) if it succeeds and –1 if it fails. If there is no DataWindow object assigned to the DataWindow control or DataStore, this method returns –1.

This method always returns –1 if the data source is external. Use a method such as ImportFile to populate the DataWindow.

Usage

After rows are retrieved, the DataWindow object’s filter is applied. Therefore, any retrieved rows that do not meet the filter criteria are immediately moved to the filter buffer and are not included in the return count.

Before you can retrieve rows for a DataWindow control or DataStore, you must specify a transaction object with SetTransObject or SetTrans. If you use SetTransObject, you must also use a SQL CONNECT statement to establish a database connection.

Normally, when you call Retrieve, any rows that are already in the DataWindow control or DataStore are discarded and replaced with the retrieved rows. You can return the code 2 in the RetrieveStart event to prevent this. In this case, Retrieve adds any retrieved rows to the ones that already exist in the buffers.

Retrieval arguments  If arguments are expected but not specified, the user is prompted for the retrieval arguments.
A retrieval argument can be null if the SELECT statement is designed to handle null values. For example, if a two-part WHERE clause is separated by OR, then either part can be null while the other matches values in the database.

**Web DataWindow client control** Calling Retrieve causes data to be retrieved on the server. Then the page is reloaded.

**Using retrieval arguments** Page parameters hold the retrieval argument values that were used for the current page. To return these values to the server for the next retrieval, specify the page parameter names and expressions that are the values of the retrieval arguments in the HTMLGen.SelfLinkArgs property.

**In case of retrieve error** All methods that reload the page perform an AcceptText before sending data back to the server. If Retrieve fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.

**Web DataWindow server component** If you need to include retrieval arguments, call RetrieveEx instead of Retrieve.

The argument for the RetrieveEx method is a string that contains the values of all the retrieval arguments expected by the DataWindow object associated with the server component.

The string has the format:

```
value1 \n value2 \n value3... \n value16
```

The values of the retrieval arguments must be separated by newline characters (\n) and individual values cannot contain newline characters as part of the value. The Web DataWindow supports up to 16 retrieval arguments.

You can specify an array for the value of a retrieval argument by separating the array values with a tab character (\t). For example, if the DataWindow expects an array for the second retrieval argument, the syntax would be:

```
value1 \n value2a \t value2b \t value2c \n value3...
```

When the retrieval arguments are passed to the page as page parameters, call SetSelfLink to provide the information to recreate the page parameters each time the page is reloaded. After you retrieve data, call Generate to render the data on a Web page in a Web DataWindow client control.

Call GetLastError and GetLastErrorString to get information about database errors that cause SetAction, Update, Retrieve, and RetrieveEx to return –1.
Retrieve

**Events** Retrieve may trigger these events:
- DBError
- RetrieveEnd
- RetrieveRow
- RetrieveStart

None of these events is triggered if the data source is external, because Retrieve always fails. You must use one of the import methods to populate the DataWindow.

**Examples**

This statement causes dw_emp1 to retrieve rows from the database.

```powerbuilder
dw_emp1.Retrieve()
```

This example illustrates how to set up a connection and then retrieve rows in the DataWindow control. A typical scenario is to establish the connection in the application’s Open event and to retrieve rows in the Open event for the window that contains the DataWindow control.

The following is a script for the application open event. SQLCA is the default transaction object. The ProfileString function is getting information about the database connection from an initialization file:

```powerbuilder
// Set up Transaction object from the INI file
SQLCA.DBMS = ProfileString("myapp.ini", 
    "Database", "DBMS", 
) SQLCA.DbParm = ProfileString("myapp.ini", 
    "Database", "DbParm", 
) // Connect to database
CONNECT USING SQLCA;
// Test whether the connect succeeded
IF SQLCA.SQLCode <> 0 THEN
    MessageBox("Connect Failed", 
        "Cannot connect to database." 
        + SQLCA.SQLErrText)
    RETURN
END IF
Open(w_main)
```

To continue the example, the open event for w_main sets the transaction object for the DataWindow control dw_main to SQLCA and retrieves rows from the database.

If no rows were retrieved or if there is an error (that is, the return value is negative), the script displays a message to the user:

```powerbuilder
long ll_rows
dw_main.SetTransObject(SQLCA)
```
ll_rows = dw_main.Retrieve()
IF ll_rows < 1 THEN MessageBox( &  
"Database Error", &  
"No rows retrieved." )

This example illustrates the use of retrieval arguments. Assume that :Salary  
and :Region are declared as arguments in the DataWindow painter and  
dw_emp has this SQL SELECT statement:

```sql
SELECT Name, emp.sal, sales.rgn From Employee, Sales
WHERE emp.sal > :Salary and sales.rgn = :Region
```

Then this statement causes dw_emp1 to retrieve employees from the database  
who have a salary greater than $50,000 and are in the northwest region:

```sql
dw_1.Retrieve(50000, "NW")
```

This example also illustrates retrieval arguments. Assume dw_EmpHist  
contains this SQL SELECT statement and emps is defined as a number array:

```sql
SELECT EmpNbr, Sal, Rgn From Employee
WHERE EmpNbr IN (:emps)
```

These statements cause dw_EmpHist to retrieve Employees from the database  
whose employee numbers are values in the array emps:

```java
Double emps[3]
emps[1] = 100
emps[2] = 200
emps[3] = 300
dw_EmpHist.Retrieve(emps)
```

The following example illustrates how to use Retrieve twice to get data meeting  
different criteria. Assume the SELECT statement for the DataWindow object  
requires one argument, the department number. Then these statements retrieve  
all rows in the database in which department number is 100 or 200.

The script for the RetrieveStart event in the DataWindow control sets the return  
code to 2 so that the rows and buffers of the DataWindow control are not  
cleared before each retrieval:

```javascript
RETURN 2
```

The script for the Clicked event for a Retrieve CommandButton retrieves the  
data with two function calls. The Reset method clears any previously retrieved  
rows, normally done by Retrieve.
Here, Retrieve is prevented from doing it by the return code in the RetrieveStart event:

```powerbuilder
dw_1.Reset()
dw_1.Retrieve(100)
dw_1.Retrieve(200)
```

For the Web DataWindow server component, if the user entered a product ID in a form to get detailed information on the product, the product ID is passed to the product report template as a page parameter. The page parameter should always exist because it comes from the calling page, but the code provides a default value anyway:

```java
String prod_id;
prod_id=(String) request.getParameter("ProdID");
if (prod_id == null){
    prod_id = "1";
}
dwGen.SetSelfLink("ProdID=" + prod_id);
dwGen.RetrieveEx(prod_id);
```

## RowCount

### Description
Obtains the number of rows that are currently available in a DataWindow control or DataStore. To determine the number of rows available, the RowCount method checks the primary buffer.

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Syntax

**PowerBuilder and Web DataWindow server component**

```java
long dwcontrol.RowCount ( )
```

**Web DataWindow client control and Web ActiveX**

```java
number dwcontrol.RowCount ( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns the number of rows that are currently available in `dwcontrol`, 0 if no rows are currently available, and –1 if an error occurs.

If `dwcontrol` is null, in PowerBuilder and Javascript the method returns null.

Usage

The primary buffer for a DataWindow control or DataStore contains the rows that are currently available for display or printing. These are the rows counted by `RowCount`. The number of currently available rows equals the total number of rows retrieved minus any deleted or filtered rows plus any inserted rows. The deleted and filtered rows are stored in the DataWindow’s delete and filter buffers.

Examples

This statement returns the number of rows currently available in `dw_Employee`:

```java
long NbrRows
NbrRows = dw_Employee.RowCount ( )
```

This example determines when the user has scrolled to the end of a DataWindow control. It compares the row count with the DataWindow property `LastRowOnPage`:

```java
dw_1.ScrollNextPage ( )
IF dw_1.RowCount ( ) = Integer (dw_1.Describe ( & "DataWindow.LastRowOnPage" )) THEN
... // Appropriate processing
END IF
```

FilteredCount
InsertRow
ModifiedCount
SetFilter
Update
**RowsCopy**

**Description**
Copies a range of rows from one DataWindow control (or DataStore object) to another, or from one buffer to another within a single DataWindow control (or DataStore).

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
ingeger dwcontrol.RowsCopy ( long startrow, long endrow, DWBuffer copybuffer, datawindow targetdw, long beforerow, DWBuffer targetbuffer)

integer dwcontrol.RowsCopy ( long startrow, long endrow, DWBuffer copybuffer, datastore targetdw, long beforerow, DWBuffer targetbuffer)

integer dwcontrol.RowsCopy ( long startrow, long endrow, DWBuffer copybuffer, datawindowchild targetdw, long beforerow, DWBuffer targetbuffer)
```

**Web ActiveX**

```activeXObject
number dwcontrol.RowsCopy (number startrow, number endrow, DWBuffer copybuffer, datawindow targetdw, number beforerow, number targetbuffer)

number dwcontrol.RowsCopy (number startrow, number endrow, DWBuffer copybuffer, datawindowchild targetdw, number beforerow, number targetbuffer)
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the DataWindow control, DataStore, or child DataWindow from which you want to copy rows.</td>
</tr>
<tr>
<td>startrow</td>
<td>The number of the first row you want to copy.</td>
</tr>
<tr>
<td>endrow</td>
<td>The number of the last row you want to copy.</td>
</tr>
</tbody>
</table>
| copybuffer | A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the DataWindow buffer from which you want to copy rows.  
For a list of valid values, see DWBuffer on page 478. |
| targetdw   | A reference to the DataWindow control or DataStore object to which you want to copy the rows. Targetdw can be the same DataWindow (or DataStore) or another DataWindow (or DataStore). |
Return value

Returns 1 if it succeeds and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

When you use the RowsCopy method, the status of the rows that are copied to the primary buffer is NewModified!. If you issue an update request, PowerBuilder sends SQL INSERT statements to the DBMS for the new rows.

When you use RowsCopy, data is not automatically retrieved for drop-down DataWindows in the target DataWindow or DataStore, as it is when you call InsertRow. You must explicitly call Retrieve for child DataWindows in the target.

When you use RowsCopy or RowsMove to populate another DataWindow, the copied data is not automatically processed by filters or sort criteria in effect on the target DataWindow. You might be required to call the Filter, GroupCalc, or Sort methods to properly process the data.

Uses for RowsCopy include:

- Making copies of one or more rows so that the users can create new rows based on existing data
- Printing a range of rows by copying selected rows to another DataWindow and printing the second DataWindow

**Buffer manipulation and query mode**

A DataWindow cannot be in query mode when you call the RowsCopy method.

Examples

This statement copies all the rows starting with the current row in dw_1 to the beginning of the primary buffer in dw_2:

```powerscript
dw_1.RowsCopy(dw_1.GetRow(), &
    dw_1.RowCount(), Primary!, dw_2, 1, Primary!)
```
This example copies all the rows starting with the current row in dw_1 to the beginning of the primary buffer in the drop-down DataWindow state_id in dw_3:

```powerbuilder
datawindowchild dwc
   dw_3.GetChild("state_id", dwc)
   dw_1.RowsCopy(dw_1.GetRow(), &dw_1.RowCount(), Primary!, dwc, 1, Primary!)
```

This example copies all the rows starting with the current row in dw_1 to the beginning of the primary buffer in the nested report d_employee:

```powerbuilder
datawindowchild dwc
   dw_composite.GetChild("d_employee", dwc)
   dw_1.RowsCopy(dw_1.GetRow(), &dw_1.RowCount(), Primary!, dwc, 1, Primary!)
```

See also

RowsDiscard
RowsMove

---

**RowsDiscard**

**Description**

Discards a range of rows in a DataWindow control. Once a row has been discarded using `RowsDiscard`, you cannot restore the row. You have to retrieve it again from the database.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
type integer dwcontrol.RowsDiscard (long startrow, long endrow, DwBuffer buffer)
```

**Web DataWindow server component**

```powerbuilder
type short dwcontrol.RowsDiscard (long startrow, long endrow, string buffer)
```

**Web ActiveX**

```powerbuilder
type number dwcontrol.RowsDiscard (number startrow, number endrow, number buffer)
```
CHAPTER 9  Methods for the DataWindow Control

DataWindow Reference

Return value

Returns 1 if it succeeds and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Use RowsDiscard when your application is finished with some of the rows in a DataWindow control and you do not want an update to affect the rows in the database. For example, you can discard rows in the delete buffer, which prevents the rows from being deleted when you call Update.

Use Reset to clear all the rows from a DataWindow control.

The RowsDiscard method triggers the RowFocusChanging and RowFocusChanged events only when the row number of the current row is changed. The current row is simply a number that indicates which row is the current row. A change in the content of the row does not trigger the events if the number of the current row remains the same.

Suppose you have a DataWindow with two rows. If the current row is row 1 and RowsDiscard discards row 1, row 2 becomes the current row, but its row number also changes from 2 to 1. The events are not fired because the current row number is still row 1. If the current row is row 2 and RowsDiscard discards row 1, the events are fired because the current row number has changed from row 2 to row 1.

Examples

This statement discards all the rows in the delete buffer for dw_1. As a result if the application later calls dw_1.Update(), the DataWindow will not submit SQL DELETE statements to the DBMS for these rows:

```
dw_1.RowsDiscard(1, dw_1.DeletedCount(), Delete!)
```

See also

Reset
RowsCopy
RowsMove
RowsMove

Description
Clears a range of rows from one DataWindow control (or DataStore) and inserts them in another. Alternatively, RowsMove moves rows from one buffer to another within a single DataWindow control (or DataStore).

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer dwcontrol.RowsMove ( long startrow, long endrow, DWBuffer movebuffer, datawindow targetdw, long beforerow, DWBuffer targetbuffer )

integer dwcontrol.RowsMove ( long startrow, long endrow, DWBuffer movebuffer, datastore targetdw, long beforerow, DWBuffer targetbuffer )

integer dwcontrol.RowsMove ( long startrow, long endrow, DWBuffer movebuffer, datawindowchild targetdw, long beforerow, DWBuffer targetbuffer )

**Web ActiveX**

number dwcontrol.RowsMove (number startrow, number endrow, number movebuffer, datawindow targetdw, number beforerow, number targetbuffer )

number dwcontrol.RowsMove (number startrow, number endrow, number movebuffer, datawindowchild targetdw, number beforerow, number targetbuffer )

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of a DataWindow control, DataStore, or child DataWindow from which you want to move rows.</td>
</tr>
<tr>
<td>startrow</td>
<td>The number of the first row you want to move.</td>
</tr>
<tr>
<td>endrow</td>
<td>The number of the last row you want to move.</td>
</tr>
<tr>
<td>movebuffer</td>
<td>A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the DataWindow buffer from which you want to move the rows. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td>targetdw</td>
<td>The name of the DataWindow control or DataStore to which you want to move the rows. Targetdw can be the same DataWindow control (or DataStore) or a different DataWindow control (or DataStore), but it cannot be a child DataWindow.</td>
</tr>
</tbody>
</table>
Return value

Returns 1 if it succeeds and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

When you use RowsMove, the rows have the status NewModified! in the target DataWindow.

If you move rows between buffers in a single DataWindow control or DataStore, PowerBuilder retains knowledge of where the rows came from, and their status is changed accordingly. For example, if you move unmodified rows from the primary buffer to the delete buffer, they are marked for deletion. If you move the rows back to the primary buffer, their status returns to NotModified!.

Note, however, that if you move rows from one DataWindow control (or DataStore) to another and back again, the rows’ status is NewModified! because they came from a different DataWindow.

The RowsMove method triggers the RowFocusChanging and RowFocusChanged events only when the row number of the current row is changed. The current row is simply a number that indicates which row is the current row. A change in the content of the row does not trigger the events if the number of the current row remains the same.

Suppose you have a DataWindow with two rows. If the current row is row 1 and RowsMove moves row 1, row 2 becomes the current row, but its row number also changes from 2 to 1. The events are not fired because the current row number is still row 1. If the current row is row 2 and RowsMove moves row 1, the events are fired because the current row number has changed from row 2 to row 1.

When you use RowsMove, data is not automatically retrieved for drop-down DataWindows in the target DataWindow, as it is when you call InsertRow. You must explicitly call Retrieve for child DataWindows in the target.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beforeRow</td>
<td>The number of the row before which you want to insert the moved rows. To insert after the last row, use any value that is greater than the number of existing rows.</td>
</tr>
<tr>
<td>targetBuffer</td>
<td>A value of the dwBuffer enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the target buffer for the rows. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
</tbody>
</table>
When you use RowsCopy or RowsMove to populate another DataWindow, the copied data is not automatically processed by filters or sort criteria in effect on the target DataWindow. You might be required to call the Filter, GroupCalc, or Sort methods to properly process the data.

Uses for RowsMove include:

- Moving several rows from the primary buffer to the delete buffer, instead of deleting them one at a time
- Moving rows from the delete buffer to the primary buffer, to implement an Undo capability in your application

**Buffer manipulation and query mode**

A DataWindow cannot be in query mode when you call the RowsMove method.

**Examples**

This statement moves all the rows starting with the first row in the delete buffer for dw_1 to the primary buffer for dw_1, thereby undeleting these rows:

```
    dw_1.RowsMove(1, dw_1.DeletedCount(), Delete!, &
                   dw_1, 1, Primary!)
```

CHAPTER 9  Methods for the DataWindow Control

SaveAs

Description
Saves the contents of a DataWindow or DataStore in the format you specify.

For syntax to save the contents of graphs in DataWindows and DataStores, see SaveAs on page 962. For syntax to save objects in OLE controls and OLE storage, see SaveAs in the PowerScript Reference.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.SaveAs ( { string filename, saveastype saveastype, boolean colheading { , encoding encoding } } )
```

**Web DataWindow server component**

```powerbuilder
short dwcontrol.SaveAs ( string filename, string saveastype, boolean colheading )
short dwcontrol.SaveAsEx ( string filename, string saveastype, boolean colheading, string encoding )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td><code>filename</code> (optional for PowerBuilder)</td>
<td>A string whose value is the name of the file in which to save the contents. If you omit <code>filename</code> or specify an empty string (&quot;&quot;), the DataWindow prompts for the filename.</td>
</tr>
<tr>
<td><code>saveastype</code> (optional for PowerBuilder)</td>
<td>A value of the SaveAsType enumerated datatype (PowerBuilder) or a string (Web DataWindow) specifying the format in which to save the contents of the DataWindow object. For a list of values, see SaveAsType on page 486.</td>
</tr>
<tr>
<td><code>colheading</code> (optional for PowerBuilder)</td>
<td>A boolean value indicating whether you want to include the DataWindow’s column headings at the beginning of the file. The default value is true. This argument is used for the following formats: Clipboard, CSV, Excel, and Text. For most other formats, column headings are always saved.</td>
</tr>
</tbody>
</table>

Working with DataStore objects

If you are working with a DataStore, you must supply the `filename` argument.
SaveAs

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| encoding (optional for PowerBuilder) | Character encoding of the file to which the data is saved. This parameter applies only to the following formats: TEXT, CSV, SQL, HTML, and DIF. If you do not specify an `encoding` parameter, the file is saved in ANSI format. Values are:  
  • EncodingANSI! (default)  
  • EncodingUTF8!  
  • EncodingUTF16LE!  
  • EncodingUTF16BE! |

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SaveAs returns null.

Usage

If you do not specify any arguments for SaveAs, PowerBuilder displays the Save As dialog box. A drop-down list lets the user specify the format of the saved data. You must specify all arguments for the Web DataWindow.

Report format (PSReport! value of SaveAsType) is the best choice if the DataWindow is a composite report. Choosing PSReport! has no effect if the DataWindow object has the RichText presentation style.

For XML!, the XML logical structure used is based on the current XML export template for the DataWindow object. You can change the export template by setting the value of the Export.XML.UseTemplate property. If no export template is specified, the default template is used.

If you use date formats in your report, you must verify that yyyy is the Short Date Style for year in the Regional Settings of the user’s Control Panel. Your program can check this with the RegistryGet function. If the setting is not correct, you can ask the user to change it manually or to have the application change it (by calling the RegistrySet function). The user might need to reboot after the setting is changed.

When you save the contents of a DataWindow to a text file, double quotes are handled in a way that enables the ImportFile method to produce the same DataWindow when the text file is imported back into PowerBuilder. Any field that is enclosed in a pair of double quotes is wrapped with three pairs of double quotes in the saved text file. Double quotes at the beginning of a text field that have no matching double quotes at the end of the field are also replaced by three double quotes in the saved text file. However, a double quote elsewhere in the field is saved as one double quote.
The behavior of the `SaveAs` method with the `EncodingANSI` parameter or with no encoding parameter is platform dependent. On the Windows and Solaris platforms, the file is always saved with ANSI encoding whether you are connected to an ANSI or Unicode database. On the Linux platform with an ANSI database connection, `SaveAs` saves the file with ANSI encoding. On the Linux platform with a Unicode database connection, if the data contains multilanguage characters, `SaveAs` converts the characters to UTF-8 and saves the file with UTF-8 encoding.

**Web ActiveX**
The Web ActiveX is a safely scriptable control and does not take actions that can affect the client’s environment. Therefore, it does not support `SaveAs`.

**Examples**

This statement saves the contents of `dw_History` to the file `G:\INVENTORY\EMPLOYEE.HIS`. The saved file is in CSV format without column headings:

```plaintext
dw_History.SaveAs("G:\INVENTORY\EMPLOYEE.HIS", & CSV!, false)
```

The following statements set the template used by the DataWindow `dw_1` to `t_report`, specify that metadata in the XMLSchema! format should be generated in a separate file, and generate the files `c:\myxml.xml` containing the DataWindow row data in XML format, and `c:\myxml.xsd` containing the XML schema used in `c:\myxml.xml`:

```plaintext
dw_1.Modify("DataWindow.Export.XML.UseTemplate = 't_report'")
dw_1.Modify("DataWindow.Export.XML.MetaDataType = XMLSchema!"")
dw_1.Modify("DataWindow.Export.XML.SaveMetaData = MetaDataExternal!")
dw_1.SaveAs("c:\myxml.xml", XML!, false)
```

The following statements generate the files `c:\dw_one.fo` containing the DataWindow presentation and data in XSL-FO format, and `c:\dw_one.pdf` containing the DataWindow presentation and data in PDF format:

```plaintext
dw_1.SaveAs("c:\dw_one.fo", XSLFO!, false)
dw_1.SaveAs("c:\dw_one.pdf", PDF!, false)
```

*DataWindow Reference* 789
SaveAsAscii

Description
Saves the contents of a DataWindow or DataStore into a standard ANSI text file.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

```powerbuilder
long dwcontrol.SaveAsAscii ( string filename {, string separatorcharacter {, string quotecharacter {, string lineending {, boolean retainnewlinechar } } } } )
```

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td>filename</td>
<td>A string whose value is the name of the file in which to save the contents.</td>
</tr>
<tr>
<td>separatorcharacter</td>
<td>A string whose value is the character to be used to delimit values. If you omit <code>separatorcharacter</code>, the default is a tab character.</td>
</tr>
<tr>
<td>quotecharacter</td>
<td>A string whose value is the character to be used to wrap values. If you omit <code>quotecharacter</code>, the default is double quote.</td>
</tr>
<tr>
<td>lineending</td>
<td>A string whose value is placed at the end of each line. If you omit <code>lineending</code>, the default is a carriage return plus a newline character (<del>r</del>n).</td>
</tr>
<tr>
<td>retainnewlinechar</td>
<td>A boolean value that determines whether line feed and carriage return characters contained within the row are converted to white space. Values are: True – line feed and carriage return characters within the row are not converted to white space False (default) – line feed and carriage return characters within the row are converted to white space</td>
</tr>
</tbody>
</table>

Return value
Returns 1 if it succeeds and –1 if an error occurs.

Usage
SaveAsAscii always saves the file with ANSI encoding. To save to a file with a different encoding, use SaveAsFormattedText.
SaveAsAscii is like SaveAs with the Text SaveAsType. However, unlike SaveAs, SaveAsAscii formats the text and saves column headers in the form in which they are displayed in the DataWindow instead of as the column name. For example, if the heading for the cust_id column is Customer ID, SaveAsAscii saves Customer ID to the text file, whereas SaveAs saves cust_id. SaveAsAscii also saves computed fields allows you to customize formats in the file.

If you do not specify custom settings, values are wrapped in double quotes and separated by tabs. A newline character (~r~n) is placed at the end of each line. Line feed and carriage return characters within each row are converted to white space.

PowerBuilder assigns a cell for each DataWindow object (which can include computed columns and group totals). If a cell is empty, PowerBuilder puts the quote character between the separator character in the output file.

**Examples**

This statement saves the contents of dw_Quarter to the file $H:\Q2\RESULTS.TXT$. The saved file uses ANSI encoding with the ampersand (&) as the separator character, and single quotes (’) as the characters used to wrap values. A new line (~r~n) is automatically inserted at each line ending.

Computed columns are included with the saved information:

```
dw_Quarter.SaveAsAscii("$H:\Q2\RESULTS.TXT","&","’")
```

SaveAsFormattedText

---

### SaveAsFormattedText

**Description**

Saves the contents of a DataWindow or DataStore into a standard text file with custom formatting.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

**Syntax**

```
long dwcontrol.SaveAsFormattedText ( string filename {}, string encoding {}, string separatorcharacter {}, string quotecharacter {}, string lineending {}, boolean retainnewlinechar {} )
```

DataWindow Reference 791
### SaveAsFormattedText

#### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td><code>filename</code></td>
<td>A string whose value is the name of the file in which to save the contents.</td>
</tr>
<tr>
<td><code>encoding</code></td>
<td>Character encoding of the file to which the data is saved.</td>
</tr>
<tr>
<td>(<code>optional</code>)</td>
<td>If you do not specify an <code>encoding</code> parameter, the file is saved in ANSI format. Values are:</td>
</tr>
<tr>
<td></td>
<td>• EncodingANSI! (default)</td>
</tr>
<tr>
<td></td>
<td>• EncodingUTF8!</td>
</tr>
<tr>
<td></td>
<td>• EncodingUTF16LE!</td>
</tr>
<tr>
<td></td>
<td>• EncodingUTF16BE!</td>
</tr>
<tr>
<td><code>separatorcharacter</code></td>
<td>A string whose value is the character to be used to delimit values. If you omit <code>separatorcharacter</code>, the default is a tab character.</td>
</tr>
<tr>
<td>(<code>optional</code>)</td>
<td><code>quotecharacter</code> A string whose value is the character to be used to wrap values. If you omit <code>quotecharacter</code>, the default is double quote.</td>
</tr>
<tr>
<td>(<code>optional</code>)</td>
<td><code>lineending</code> A string whose value is placed at the end of each line. If you omit <code>lineending</code>, the default is a carriage return plus a newline character (<del>r</del>n).</td>
</tr>
<tr>
<td>(<code>optional</code>)</td>
<td><code>retainnewlinechar</code> A boolean value that determines whether line feed and carriage return characters contained within the row are converted to white space. Values are:</td>
</tr>
<tr>
<td></td>
<td>• True – line feed and carriage return characters within the row are not converted to white space</td>
</tr>
<tr>
<td></td>
<td>• False (default) – line feed and carriage return characters within the row are converted to white space</td>
</tr>
</tbody>
</table>

#### Usage

`SaveAsFormattedText` is like `SaveAs` with the Text `SaveAsType`. However, unlike `SaveAs`, `SaveAsFormattedText` formats the text and saves column headers in the form in which they are displayed in the DataWindow instead of as the column name. For example, if the heading for the `cust_id` column is `Customer ID`, `SaveAsFormattedText` saves `Customer ID` to the text file, whereas `SaveAs` saves `cust_id` to the text file. `SaveAsFormattedText` also saves computed fields allows you to customize formats in the file.

If you do not specify custom settings, values are wrapped in double quotes and separated by tabs. A newline character (~r~n) is placed at the end of each line. Line feed and carriage return characters within each row are converted to white space.

Return value

Returns 1 if it succeeds and –1 if an error occurs.
PowerBuilder assigns a cell for each DataWindow object (which can include computed columns and group totals). If a cell is empty, PowerBuilder puts the *quotecharacter* between the *separatorcharacter* in the output file.

**Examples**  
This statement saves the contents of *dw_Quarter* to the file *H:\Q2\RESULTS.TXT*. The saved file uses UTF-16LE encoding with the ampersand (&) as the separator character, single quote (’) as the character used to wrap values and the default line ending (~r~n). Computed columns are included with the saved information:

```powerbuilder
  dw_Quarter.SaveAsFormattedText("H:\Q2\RESULTS.TXT", EncodingUTF16LE!, "&", ")
```

**SaveInk**

**Description**  
Saves overlay ink to a file or blob from an InkPicture control.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
  integer dwcontrol.SaveInk ( string name, long rownumber, blob blob )
  integer dwcontrol.SaveInk ( string name, long rownumber,
                               string filename, inkpersistenceformat format, inkcompressionmode mode )
```

**Argument** | **Description**
--- | ---
*dwcontrol* | A reference to a DataWindow control.
*name* | The name of the InkPicture control from which you want to save the ink.
*rownumber* | The number of the row that contains the ink to be saved.
*blob* | The name of a blob passed by reference that will hold the ink in the control.
*filename* | A string containing the name and location of a file that will hold the ink in the control.
## SaveInk

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| format (optional) | A value of the InkPersistenceFormat enumerated variable that specifies the format in which you want to save the ink. Values are:  
  - Base64GIFFormat!  
  - Base64InkSerializedFormat!  
  - GIFFormat!  
  - InkSerializedFormat! (default) |
| mode (optional) | A value of the InkCompressionMode enumerated variable that specifies the compression mode in which you want to save the ink. Values are:  
  - DefaultCompression! (default)  
  - MaximumCompression!  
  - NoCompression! |

**Return value**

Integer. Returns 1 for success and -1 for failure.

**Usage**

Use the SaveInk method to save annotations made to an image in an InkPicture control in a DataWindow to a separate file or blob.

When you save ink to a blob, it is saved in InkSerialized Format (ISF). Saving ink to a blob provides the best performance because the ink is read directly from the ink data cache.

InkSerializedFormat! provides the most compact persistent ink representation. This format can be embedded inside a binary document format or added to the clipboard. Base64InkSerializedFormat! encodes the ISF format as a base64 stream, which allows the ink to be encoded in an XML or HTML file.

GIFFormat! saves the image in a Graphics Interchange Format (GIF) file in which ISF is embedded as metadata. This format can be viewed in applications that are not ink enabled. Base64GIFFormat! is persisted by using a base64 encoded fortified GIF. Use this format if the ink is to be encoded directly in an XML or XHTML file and will be converted to an image at a later time. It supports XSLT transformations to HTML.

**Examples**

The following example saves the ink in an InkPicture control in row 3 of a DataWindow object into an ISF file with default compression:

```plaintext
int li_return
string ls_pathname, ls_filename

GetFileSaveName("Save As", ls_pathname, &ls_filename, "ISF")
li_return = dw_1.SaveInk("inkpic_1", 3, ls_pathname)
```
The following example saves the ink in an InkPicture control in row 5 of a DataWindow object into a GIF file with maximum compression:

```powershell
int li_return
string ls_pathname, ls_filename

GetFileSaveName("Save As", ls_pathname, 
    & ls_filename, "GIF")
li_return = dw_1.SaveInk("inkpic_1", 5, 
    & ls_pathname, GIFFormat!, MaximumCompression!)
```

The following example saves the ink in an InkPicture control in the current row of a DataWindow object into a blob:

```powershell
int li_return
blob lb_blob

li_return = dw_1.SaveInk("inkpic_1", 
    & dw_1.GetRow(), lb_blob)
```

SaveInkPic

### SaveInkPic

**Description**
Saves a picture and optionally overlay ink to a file from an InkPicture control.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powershell
integer dwcontrol.SaveInkPic( string name, long rownumber, string filename, integer format {, boolean withink })
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the InkPicture control from which you want to save the picture.</td>
</tr>
<tr>
<td>rownumber</td>
<td>The number of the row that contains the picture to be saved.</td>
</tr>
<tr>
<td>filename</td>
<td>A string containing the name and location of a file that will hold the picture in the control.</td>
</tr>
</tbody>
</table>
**Scroll**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>An integer specifying the format in which the picture is to be saved. Values are: 0 – BMP (bitmap) 1 – JPEG (Joint Photographic Experts Group) 2 – GIF (Graphics Interchange Format) 3 – TIFF (Tagged Image File Format) 4 – PNG (Portable Network Graphics)</td>
</tr>
<tr>
<td>within</td>
<td>A boolean specifying whether overlay ink should be saved with the picture. Values are: True – overlay ink is saved with the picture (default) False – overlay ink is not saved with the picture</td>
</tr>
</tbody>
</table>

**Return value**

Integer. Returns 1 for success and –1 for failure.

**Usage**

Use the SavInkPic method to save the image in an InkPicture control in a DataWindow to a file with or without any ink annotations that have been made to it. By default, the ink is saved with the image.

**Examples**

The following example saves the image in an InkPicture control in row 3 of a DataWindow object into a GIF file without any ink annotations:

```powershell
int li_return
string ls_pathname, ls_filename

GetFileSaveName("Save As", ls_pathname, & ls_filename, "GIF")
li_return = dw_1.SaveInk(inkpic_1, 3, & ls_pathname, 2, false)
```

**See also**

ResetInk
SaveInkPic

---

**Scroll**

**Description**

Scrolls the edit control of a DataWindow a specified number of lines up or down.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Syntax

**PowerBuilder**

```plaintext
long dwcontrol_scroll ( long number )
```

**Web ActiveX**

```plaintext
number dwcontrol_scroll ( number number )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control. Scroll affects the edit control of the DataWindow.</td>
</tr>
<tr>
<td><code>number</code></td>
<td>A value specifying the direction and number of lines you want to scroll. To scroll down, use a positive value. To scroll up, use a negative value.</td>
</tr>
</tbody>
</table>

Return value

Scroll returns the line number of the first visible line in `dwcontrol` if it succeeds. Scroll returns –1 if an error occurs. If any argument’s value is null, Scroll returns null.

Usage

If the number of lines left in the list is less than the number of lines that you want to scroll, then Scroll will scroll to the beginning or end, depending on the direction specified.

Examples

This statement scrolls `mle_Employee` down 4 lines:

```plaintext
mle_Employee_scroll(4)
```

This statement scrolls `mle_Employee` up 4 lines:

```plaintext
mle_Employee_scroll(-4)
```

See also

The following related methods implement scrolling in a DataWindow or a PowerBuilder RichTextEdit control:

- ScrollNextPage
- ScrollNextRow
- ScrollPriorPage
- ScrollPriorRow
- ScrollToRow

**ScrollFirstPage**

**Description**

Scrolls a Web DataWindow control to the first page, displaying the result set’s first group of rows in the Web page. (A page is the number of rows that are displayed in the DataWindow control at one time.) ScrollFirstPage changes the current row, but not the current column.
ScrollFirstPage

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
</tbody>
</table>

Syntax

**Web DataWindow client control**

```plaintext
number dwcontrol.ScrollFirstPage ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and –1 if an error occurs.

If `dwcontrol` is null, the method returns null.

Usage

Calling `ScrollFirstPage` causes the page to be reloaded with another set of rows from the result set.

If the DataWindow object has retrieval arguments, they must be specified in the `HTMLGen.SelfLinkArgs` property. For more information, see the `HTMLGen` property, the `Retrieve` method, and the DataWindow Programmers Guide.

All methods that reload the page perform an `AcceptText` before sending data back to the server. If the method fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the `ItemError` event occurs.

**Events**  `ScrollNextPage` may trigger these events:

- `ItemChanged`
- `ItemError`
- `ItemFocusChanged`
- `RowFocusChanged`
- `RowFocusChanging`

**Examples**

This statement scrolls `dw_employee` to the first page:

```
dw_employee.ScrollFirstPage();
```

See also

- `ScrollLastPage`
- `ScrollNextPage`
- `ScrollPriorPage`
ScrollLastPage

Description
Scrolls a Web DataWindow control to the last page, displaying the result set’s last group of rows in the Web page. (A page is the number of rows that are displayed in the DataWindow control at one time.) ScrollLastPage changes the current row, but not the current column.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
</tbody>
</table>

Syntax

Web DataWindow client control

number dwcontrol.ScrollLastPage ( )

Argument | Description
----------|-----------------

dwcontrol | A reference to a DataWindow control

Return value
Returns 1 if it succeeds and –1 if an error occurs. If dwcontrol is null, the method returns null.

Usage
Calling ScrollLastPage causes the page to be reloaded with another set of rows from the result set.

If the DataWindow object has retrieval arguments, they must be specified in the HTMLGen.SelfLinkArgs property. For more information, see the HTMLGen.property, the Retrieve method, and the DataWindow Programmers Guide.

All methods that reload the page perform an AcceptText before sending data back to the server. If the method fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.

Events
ScrollNextPage may trigger these events:

- ItemChanged
- ItemError
- ItemFocusChanged
- RowFocusChanged
- RowFocusChanging

Examples
This statement scrolls dw_employee to the last page:

```javascript
dw_employee.ScrollLastPage();
```

</tr>
<tr>
<td>A RichTextEdit DataWindow to view the next page within the document (PowerBuilder only)</td>
<td>Syntax 2</td>
</tr>
</tbody>
</table>

Syntax 1

For DataWindow controls and child DataWindows

Description

Scrolls a DataWindow control forward one page, displaying the next group of rows in the DataWindow’s display area. (A page is the number of rows that can be displayed in the DataWindow control at one time.) ScrollNextPage changes the current row, but not the current column.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
long dwcontrol.ScrollNextPage ()
```

**Web DataWindow client control and Web ActiveX**

```powershell
number dwcontrol.ScrollNextPage ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns the number of the row displayed at the top of the DataWindow control when the scroll finishes or tries to scroll past the last row. ScrollNextPage returns 1 with nested or composite reports and child DataWindows since, in these cases, the current row cannot be changed. ScrollNextPage returns –1 if an error occurs.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

Usage

ScrollNextPage does not highlight the current row. Use SelectRow to let the user know what row is current.
For an example that uses RowCount and Describe to check whether the user has scrolled to the last page, see RowCount.

**Web DataWindow** Calling ScrollNextPage causes the page to be reloaded with another set of rows from the result set.

If the DataWindow object has retrieval arguments, they must be specified in the HTMLGen.SelfLinkArgs property. For more information, see the HTMLGen.property, the Retrieve method, and the *DataWindow Programmers Guide*.

All methods that reload the page perform an AcceptText before sending data back to the server. If the method fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.

**Events** ScrollNextPage can trigger these events:
- ItemChanged
- ItemError
- ItemFocusChanged
- RowFocusChanged
- RowFocusChanging

**Examples**

This statement scrolls dw_employee forward one page:

```
dw_employee.ScrollNextPage()
```

ScrollPriorRow
ScrollToRow
SelectRow

**Syntax 2**

**For RichTextEdit DataWindows**

Scrolls to the next page of the document in a RichTextEdit DataWindow.

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>
ScrollNextRow

Syntax

PowerBuilder

integer %windowName.%ScrollNextPage ( )

Argument | Description
---|---
%windowName | A reference to a DataWindow control. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.

Return value
Returns 1 if it succeeds and -1 if an error occurs. If %windowName is null, in PowerBuilder and JavaScript the method returns null.

Usage
A RichTextEdit DataWindow contains multiple instances of the document, one instance for each row. When the last page of the document for one row is visible, calling %ScrollNextPage advances to the first page for the next row.

PowerBuilder RichTextEdit control
You can use the same syntax with a PowerBuilder RichTextEdit control. See %ScrollNextPage in the PowerScript Reference.

Examples
This statement scrolls to the next page of the RichText document in the DataWindow control dw_rpt. If there are multiple instances of the document, it can scroll to the next instance:

dw_rpt.%ScrollNextPage()

See also
Scroll
ScrollNextRow
ScrollPriorPage
ScrollPriorRow

ScrollNextRow

Scrolls to the next row in a DataWindow control.

To scroll | Use
---|---
To the next row in a DataWindow, making the row current (when the DataWindow does not have the RichTextEdit presentation style) | Syntax 1
To the next instance of a document associated with a row in a RichTextEdit DataWindow (PowerBuilder only) | Syntax 2
Syntax 1  For DataWindow controls and child DataWindows

Description  Scrolls a DataWindow control to the next row (forward one row). ScrollNextRow changes the current row, but not the current column.

Applies to  

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax  

**PowerBuilder**

long  

dwcontrol.ScrollNextRow ()

**Web ActiveX**

number  

dwcontrol.ScrollNextRow ()

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow</td>
</tr>
</tbody>
</table>

Return value  

Returns the number of the row displayed at the top of the DataWindow control when the scroll finishes or tries to scroll past the last row. ScrollNextRow returns –1 if an error occurs.

If  
dwcontrol  is null, in PowerBuilder and JavaScript the method returns null.

Usage  

After you call ScrollNextRow, the row after the current row becomes the new current row. If that row is already visible, the displayed rows do not change. If it is not visible, the displayed rows move up to display the row.

ScrollNextRow does not highlight the row. Use SelectRow to let the user know what row is current.

Events  

ScrollNextRow triggers these events in the order shown:

- RowFocusChanging
- RowFocusChanged
- ItemFocusChanged
- ScrollVertical

You should not use ScrollNextRow in the ScrollVertical event. Doing so causes this series of events to be triggered repeatedly until the last row in the DataWindow is reached.

Examples  

This statement scrolls dw_employee to the next row:

dw_employee.ScrollNextRow()  

See also  

Scroll  

ScrollNextPage
**ScrollNextRow**

ScrollPriorPage  
ScrollPriorRow  
ScrollToRow  
SelectRow

### Syntax 2

**For RichTextEdit DataWindows**

Scrolls to the next instance of the document in a RichTextEdit DataWindow.

**Description**

Scrolls to the next instance of the document in a RichTextEdit DataWindow.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
inget rtename ScrollNextRow ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtename</td>
<td>A reference to a DataWindow control in which you want to scroll to the next document instance. Each instance is associated with a DataWindow row. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

**Usage**

A DataWindow control with a RichTextEdit DataWindow object has multiple instances of the RichText document, where each instance is associated with one row of retrieved data.

`ScrollNextRow` advances to the next instance of the RichTextEdit document. In contrast, repeated calls to `ScrollNextPage` advance through all the pages of the document instance and then on to the pages for the next row.

**PowerBuilder RichTextEdit control**

You can use the same syntax with any PowerBuilder RichTextEdit control. See `ScrollNextRow` in the *PowerScript Reference*.

**Examples**

This statement scrolls to the next instance of the RichText document in the DataWindow control `dw_rpt`. (Each document instance is associated with a row of data):

```powerbuilder
dw_rpt . ScrollNextRow ()
```
ScrollPriorPage

Scrolls to the prior page in a DataWindow control.

### Syntax 1

**For DataWindow controls and child DataWindows**

Scrolls a DataWindow control backward one page, displaying another group of rows in the DataWindow’s display area. (A page is the number of rows that can be displayed in the DataWindow control at one time.) ScrollPriorPage changes the current row but not the current column.

**Description**

A RichTextEdit DataWindow to view the prior page within the document (PowerBuilder only)

**Apply to**

- **DataWindow type**: DataWindow control, DataWindowChild object
- **Method applies to**: PowerBuilder DataWindow control, DataWindowChild object
- **Method applies to**: Web Client control
- **Method applies to**: Web ActiveX DataWindow control, DataWindowChild object

**Syntax**

- **PowerBuilder**

  ```
  long dwcontrol.ScrollPriorPage ( )
  ```

- **Web DataWindow client control and Web ActiveX**

  ```
  number dwcontrol.ScrollPriorPage ( )
  ```

**Argument | Description**

- `dwcontrol` | The name of the DataWindow control or child DataWindow you want to page (scroll) to the prior page

**Return value**

Returns the number of the row displayed at the top of the DataWindow control when the scroll finishes or tries to scroll past the first row. ScrollPriorPage returns -1 if an error occurs.
If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

`ScrollPriorPage` does not highlight the current row. Use `SelectRow` to let the user know what row is current.

**Web DataWindow** Calling `ScrollNextPage` causes the page to be reloaded with another set of rows from the result set.

If the DataWindow object has retrieval arguments, they must be specified in the `HTMLGen.SetLinkArgs` property. For more information, see the `HTMLGen.property`, the `Retrieve` method, and the *DataWindow Programmers Guide*.

All methods that reload the page perform an `AcceptText` before sending data back to the server. If `DeleteRow` fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the `ItemError` event occurs.

**Events** `ScrollPriorPage` can trigger these events:

- `ItemChanged`
- `ItemError`
- `ItemFocusChanged`
- `RowFocusChanged`
- `RowFocusChanging`

**Examples**

This statement scrolls `dw_employee` backward one page:

```
dw_employee.ScrollPriorPage()
```

**See also**

---

### Syntax 2

**For RichTextEdit DataWindows**

Scrolls to the prior page of the document in a RichTextEdit DataWindow.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>
Syntax

**PowerBuilder**

```powerbuilder
integer rtename.ScrollPriorPage ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtename</td>
<td>The name of the DataWindow control in which you want to scroll to the prior page. The DataWindow object in the DataWindow control must be a</td>
</tr>
<tr>
<td></td>
<td>RichTextEdit DataWindow.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

**Usage**

A RichText DataWindow contains multiple instances of the document, one instance for each row. When the first page of the document for one row is visible, calling `ScrollPriorPage` goes to the last page for the prior row.

**PowerBuilder RichTextEdit control**

You can use the same syntax with any PowerBuilder RichTextEdit control. See `ScrollPriorPage` in the *PowerScript Reference*.

**Examples**

This statement scrolls to the prior page of the RichText document in the DataWindow control `dw_rpt`. If there are multiple instances of the document, it can scroll to the prior instance:

```
dw_rpt.ScrollPriorPage()
```

**See also**

Scroll
ScrollNextPage
ScrollNextRow
ScrollPriorRow

---

**ScrollPriorRow**

Scrolls to the prior row in a DataWindow control.

<table>
<thead>
<tr>
<th>To scroll</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>To the prior row in a DataWindow, making the row current (when the DataWindow does not have the RichTextEdit presentation style)</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>To the prior instance of a document associated with a row in a RichTextEdit control or RichTextEdit DataWindow</td>
<td>Syntax 2</td>
</tr>
</tbody>
</table>
ScrollPriorRow

Syntax 1 For DataWindow controls and child DataWindows

Scrolls a DataWindow control backward one row. ScrollPriorRow changes the current row but not the current column.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

long *dwcontrol*.ScrollPriorRow ( )

**Web ActiveX**

number *dwcontrol*.ScrollPriorRow ( )

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>dwcontrol</em></td>
<td>A reference to a DataWindow or child DataWindow</td>
</tr>
</tbody>
</table>

Return value

Returns the number of the row displayed at the top of the DataWindow control when the scroll finishes or tries to scroll past the first row. ScrollPriorRow returns –1 if an error occurs.

If *dwcontrol* is null, in PowerBuilder and JavaScript the method returns null.

Usage

After you call ScrollPriorRow, the row before the current row becomes the new current row. If that row is already visible, the displayed rows do not change. If it is not visible, the displayed rows move down to display the row.

ScrollPriorRow does not highlight the row. Use SelectRow to let the user know what row is current.

Events

ScrollPriorRow triggers these events in the order shown:

- RowFocusChanging
- RowFocusChanged
- ItemFocusChanged
- ScrollVertical

You should not use ScrollPriorRow in the ScrollVertical event. Doing so causes this series of events to be triggered repeatedly until the first row in the DataWindow is reached.

Examples

This statement scrolls dw_employee to the prior row:

```powerbuilder
    dw_employee.ScrollPriorRow()
```
See also Scroll
ScrollNextPage
ScrollNextRow
ScrollPriorPage
ScrollToRow
SelectRow

Syntax 2 For RichTextEdit DataWindows

Description Scrolls to the prior instance of the document in a RichTextEdit DataWindow.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
integer rname.ScrollPriorRow ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rname</td>
<td>The name of the DataWindow control in which you want to scroll to the prior document instance. Each instance is associated with a DataWindow row. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and −1 if an error occurs.

Usage

A DataWindow control with a RichText DataWindow object has multiple instances of the RichText document, where each instance is associated with one row of retrieved data.

ScrollPriorRow goes to the prior instance of the RichTextEdit document. In contrast, repeated calls to ScrollPriorPage pages back through all the pages of the document instance and then back to the pages for the prior row.

**PowerBuilder RichTextEdit control**

You can use the same syntax with any PowerBuilder RichTextEdit control. See ScrollPriorRow in the *PowerScript Reference*.

Examples

This statement scrolls to the prior instance of the RichText document in the DataWindow control dw_1. (Each document instance is associated with a row of data):
ScrollToRow

Scrolls a DataWindow control to the specified row. ScrollToRow changes the current row but not the current column.

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

### Syntax

**PowerBuilder**

```powershell
integer dwcontrol.ScrollToRow ( long row )
```

**Web ActiveX**

```javascript
number dwcontrol.ScrollToRow ( number row )
```

### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row to which you want to scroll. If row is 0, ScrollToRow scrolls to the first row. If row is greater than the last row number, it scrolls to the last row. If row is visible without scrolling, the DataWindow does not scroll.</td>
</tr>
</tbody>
</table>

### Return value

Returns the number of the row to which the DataWindow scrolls if it succeeds and –1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

### Usage

After you call ScrollToRow, the specified row becomes the new current row. If that row is already visible, the displayed rows do not change. If the row is not visible, the displayed rows change to display the row.

ScrollToRow does not highlight the row. Use SelectRow to let the user know what row is current.
**Events** ScrollToRow can trigger these events:
- ItemChanged
- ItemError
- ItemFocusChanged
- RowFocusChanged

**Examples**
This statement scrolls to row 10 and makes it current in the DataWindow control `dw_employee`:

```
dw_employee.ScrollToRow(10)
```

**See also**
- `Scroll`
- `ScrollNextPage`
- `ScrollNextRow`
- `ScrollPriorPage`
- `ScrollPriorRow`
- `SelectRow`

---

**SelectedLength**

**Description**
Determines the total number of characters in the selected text in an edit control, including spaces and line endings.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
long dwcontrol.SelectedLength()
```

**Web ActiveX**

```
number dwcontrol.SelectedLength()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control. <code>SelectedLength</code> reports the length of the selected text in the edit control over the current row and column.</td>
</tr>
</tbody>
</table>

**Return value**

Returns the length of the selected text in `dwcontrol`. If no text is selected, `SelectedLength` returns 0. If an error occurs, it returns -1.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.
SelectedLine

Usage
The characters that make up a line ending, produced by typing Ctrl+Enter or Enter, are different on different platforms. On Windows, they are a carriage return plus a line feed and equal two characters when calculating the length. On other platforms, a line ending can be a single character. A line that wraps has no line-ending character.

RichText DataWindows
For rich text controls, a carriage return plus a line feed always count as a single character when calculating the text length.

PowerBuilder environment
For use with other PowerBuilder controls, see SelectedLength in the PowerScript Reference.

Examples
If the selected text in the DataWindow dw_Contact is John Smith, then this example sets the variable to 10, the number of selected characters:

```powerbuilder
integer li_length
li_length = dw_Contact.SelectedLength()
```

See also
SelectedLine
SelectedStart
TextLine

SelectedLine

Description
Obtains the number of the line that contains the insertion point in an editable control.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
long dwcontrol.SelectedLine ()
```

**Web ActiveX**

```powerbuilder
number dwcontrol.SelectedLine ()
```
Return value
Returns the number of the line containing the insertion point in *dwcontrol*. If an error occurs, `SelectedLine` returns -1. If *dwcontrol* is null, `SelectedLine` returns null.

Usage
The insertion point can be at the beginning or end of the selection. Therefore, `SelectedLine` can return the first or last selected line, depending on the position of the insertion point.

**PowerBuilder environment**
For use with other PowerBuilder controls, see `SelectedLine` in the *PowerScript Reference*.

**Examples**
If the insertion point is positioned anywhere in line 5 of the MultiLineEdit `mle_Contact`, the following example sets li_SL to 5:

```powerbuilder
integer li_SL
li_SL = mle_Contact. SelectedLine()
```

In this example, the line the user selects in the MultiLineEdit `mle_winselect` determines which window to open:

```powerbuilder
integer li_SL

li_SL = mle_winselect. SelectedLine()
IF li_SL = 1 THEN
  Open(w_emp_data)
ELSEIF li_SL = 2 THEN
  Open(w_dept_data)
END IF
```

**See also**
Position
SelectedText
TextLine

SelectRow

Description
Highlights or removes highlights from rows in a DataWindow control or DataStore. You can select all rows or a single row. SelectRow does not affect which row is current. It does not select rows in the database.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

PowerBuilder

integer dwcontrol.SelectRow ( long row, boolean select )

Web DataWindow client control and Web ActiveX

number dwcontrol.SelectRow ( number row, boolean select )

Argument | Description
---|---
dwcontrol | A reference to a DataWindow control, DataStore, or child DataWindow.
row | A value identifying the row you want to select or deselect. Specify 0 to select or deselect all rows.
select | A boolean value that determines whether the row is selected or not selected:
  - True – Select the row(s) so that they are highlighted.
  - False – Deselect the row(s) so that they are not highlighted.

Return value
Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null. If there is no DataWindow object assigned to the DataWindow control or DataStore, the method returns 1.

Usage
If a row is already selected and you specify that it be selected (boolean is true), it remains selected. If a row is not selected and you specify that it not be selected (boolean is false), it remains unselected.

Examples
This statement selects the fifteenth row in dw_employee:

dw_employee.SelectRow(15, true)
As the script for a DataWindow’s Clicked event, this example removes highlighting from all rows and then highlights the row the user clicked. `Row` is an argument passed to the event script:

```powershell
This.SelectRow(0, false)
This.SelectRow(row, true)
```

### See also
- `IsRowSelected`
- `IsSelected`

## SelectedStart

Reports the position of the first selected character in the edit control.

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

### Syntax

- **PowerBuilder**
  ```powershell
  long dwcontrol.SelectedStart()
  ```

- **Web ActiveX**
  ```javascript
  number dwcontrol.SelectedStart()
  ```

### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control. It reports the starting position in the edit control over the current row and column.</td>
</tr>
</tbody>
</table>

### Return value

Returns the starting position of the selected text in `dwcontrol`. If no text is selected, `SelectedStart` returns the position of the character immediately following the insertion point. If an error occurs, `SelectedStart` returns -1.

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

### Usage

`SelectedStart` counts from the start of the text and includes spaces and line endings.

### PowerBuilder environment

For use with RichTextEdit and other PowerBuilder controls, see `SelectedStart` in the `PowerScript Reference`.
**SelectedText**

**Examples**

If the edit control for the DataWindow control dw_rpt contains Closed for Vacation July 3 to July 10, and Vacation is selected, then this example sets the variable to 12 (the position of the first character in Vacation):

```plaintext
integer li_Start
li_Start = dw_rpt.SelectedStart()
```

**See also**

Position
SelectedLength
SelectedLine

---

**SelectedText**

**Description**

Obtains the selected text in the edit control of a DataWindow control.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```plaintext
string dwcontrol.SelectedText() 
```

**Web ActiveX**

```plaintext
string dwcontrol.SelectedText() 
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control. The method reports the selected text in the edit control over the current row and column.</td>
</tr>
</tbody>
</table>

**Return value**

Returns the selected text in `dwcontrol`. If there is no selected text or if an error occurs, `SelectedText` returns the empty string ("").

If `dwcontrol` is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

**PowerBuilder environment**

For use with RichTextEdit and other PowerBuilder controls, see `SelectedText` in the *PowerScript Reference.*
Examples

If the text in the edit control of the DataWindow dw_rpt is James B. Smith and James B. is selected, these statements set the value of the string variable to James B:

```pascal
string ls_emp_fname
ls_emp_fname = dw_rpt.SelectedText()
```

See also

SelectText

### SelectRow

**Description**

Highlights or removes highlights from rows in a DataWindow control or DataStore. You can select all rows or a single row. SelectRow does not affect which row is current. It does not select rows in the database.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```pascal
integer dwcontrol.SelectRow ( long row, boolean select )
```

**Web ActiveX**

```pascal
number dwcontrol.SelectRow ( number row, boolean select )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>row</td>
<td>A value identifying the row you want to select or deselect. Specify 0 to select or deselect all rows.</td>
</tr>
<tr>
<td>select</td>
<td>A boolean value that determines whether the row is selected or not selected:</td>
</tr>
<tr>
<td></td>
<td>• True – Select the row(s) so that they are highlighted.</td>
</tr>
<tr>
<td></td>
<td>• False – Deselect the row(s) so that they are not highlighted.</td>
</tr>
</tbody>
</table>
**SelectText**

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null. If there is no DataWindow object assigned to the DataWindow control or DataStore, the method returns 1.

**Usage**
If a row is already selected and you specify that it be selected (boolean is true), it remains selected. If a row is not selected and you specify that it not be selected (boolean is false), it remains unselected.

**Examples**
This statement selects the fifteenth row in dw_employee:

```plaintext
dw_employee.SelectRow(15, true)
```

As the script for a DataWindow’s Clicked event, this example removes highlighting from all rows and then highlights the row the user clicked. Row is an argument passed to the event script:

```plaintext
This.SelectRow(0, false)
This.SelectRow(row, true)
```

**See also**
IsSelected

---

**SelectText**

Selects text in an edit control.

<table>
<thead>
<tr>
<th>To select text in</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>A DataWindow when the DataWindow does not have the RichTextEdit presentation style</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>A DataWindow whose object has the RichTextEdit presentation style (PowerBuilder only)</td>
<td>Syntax 2</td>
</tr>
</tbody>
</table>

**Syntax 1**

**For DataWindows with standard edit styles**

Selects text in an editable control. You specify where the selection begins and how many characters to select.

**Apply to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Syntax

**PowerBuilder**

long *dwcontrol.SelectText* ( long *start*, long *length* )

**Web ActiveX**

number *dwcontrol.SelectText* ( number *start*, number *length* )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>dwcontrol</em></td>
<td>A reference to a DataWindow control.</td>
</tr>
<tr>
<td><em>start</em></td>
<td>A numeric value specifying the position at which you want to start the selection.</td>
</tr>
<tr>
<td><em>length</em></td>
<td>A numeric value specifying the number of characters you want to select. If <em>length</em> is 0, no text is selected but SelectText moves the insertion point to the location specified in <em>start</em>.</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of characters selected. If an error occurs, SelectText returns –1.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

If the control does not have the focus when you call SelectText, then the text is not highlighted until the control has focus. To set focus on the control so that the selected text is highlighted, call the SetFocus function.

To select text in a DataWindow with the RichTextEdit presentation style, use Syntax 2.

**PowerBuilder environment**

For use with other PowerBuilder controls, see SelectText in the *PowerScript Reference*.

**Examples**

This statement sets the insertion point at the end of the text in the DataWindow edit control:

```
dw_1.SelectText(dw_1.GetText(), 0)
```

This statement selects the entire contents of the DataWindow edit control:

```
dw_1.SelectText(1, Len(dw_1.GetText()))
```

The rest of these examples assume the DataWindow edit control contains Boston Street.

The following statement selects the string ost and returns 3:

```
dw_1.SelectText(2, 3)
```
The next statement selects the string oston Street and returns 12:

```powerbuilder
dw_1.SelectText(2, Len(dw_1.GetText()))
```

These statements select the string Bos, returns 3, and sets the focus to the DataWindow control so that Bos is highlighted:

```powerbuilder
dw_1.SelectText(1, 3)
dw_1.SetFocus()
```

See also

- Position
- SelectedText
- TextLine

### Syntax 2

**For RichTextEdit DataWindows**

Selects text beginning and ending at a line and character position in a RichText DataWindow.

#### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

#### Syntax

```powerbuilder
long rtedwcontrol.SelectText ( long fromline, long fromchar, longtoline, long tochar { band band } )
```

#### Argument

- **rtdwcontrol**: A reference to the DataWindow control in which you want to select text. The DataWindow object in the DataWindow control must have the RichText presentation style.
- **fromline**: A value specifying the line number where the selection starts.
- **fromchar**: A value specifying the number in the line of the first character in the selection.
- **toline**: A value specifying the line number where the selection ends. To specify an insertion point, set `toline` and `tochar` to 0.
- **tochar**: A value specifying the number in the line of the character before which the selection ends.
CHAPTER 9  Methods for the DataWindow Control

Return value
Returns the number of characters selected. A carriage return with a line feed counts as a single character. If an error occurs SelectText returns –1. If any argument’s value is null, it returns null.

Usage
The insertion point is at the “to” end of the selection—that is, the position specified by toline and tochar. If toline and tochar are before fromline and fromchar, then the insertion point is at the beginning of the selection.

You cannot specify 0 for a character position when making a selection.

You cannot always use the values returned by Position to make a selection. Position can return a character position of 0 when the insertion point is at the beginning of a line.

To select an entire line, set the insertion point and call SelectTextLine. To select the rest of a line, set the insertion point and call SelectText with a character position greater than the line length.

PowerBuilder environment
For use with other PowerBuilder controls, see SelectText in the PowerScript Reference.

Examples
SelectText is used in the same way for RichTextEdit controls and RichText DataWindow controls. For sample code, see the examples for the RichTextEdit control in the PowerScript Reference.

SelectTextWord

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>band (optional)</td>
<td>A value of the Band enumerated datatype specifying the band in which to make the selection. Values are:</td>
</tr>
<tr>
<td></td>
<td>• Detail!</td>
</tr>
<tr>
<td></td>
<td>• Header!</td>
</tr>
<tr>
<td></td>
<td>• Footer!</td>
</tr>
<tr>
<td></td>
<td>The default is the band that contains the insertion point.</td>
</tr>
</tbody>
</table>
SelectTextAll

Description
Selects all the contents of a RichTextEdit control including any special characters such as carriage return and end-of-file markers.

Applies to
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```plaintext
integer rtename.SelectTextAll ( band band )
```

**Argument** | **Description**
---|---
.rtename | A reference to a DataWindow control in which you want to select all the contents. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.
.band (optional) | A value of the Band enumerated datatype specifying the band in which you want to select all the text. Values are:
• Detail!
• Header!
• Footer!
The default is the band that contains the insertion point.

Return value
Returns the number of characters selected. A carriage return with a line feed counts as a single character. If an error occurs, SelectTextAll returns –1.

Usage

**PowerBuilder RichTextEdit control**
You can use the same syntax with a PowerBuilder RichTextEdit control. See SelectTextAll in the *PowerScript Reference*.

Examples
This statement selects all the text in the detail band:

```plaintext
dw_1.SelectTextAll()
```

This statement selects all the text in the header band:

```plaintext
dw_1.SelectTextAll(Header!)
```

See also
SelectedText
SelectText
SelectTextLine
SelectTextWord
SelectTextLine

Description
Selects the line containing the insertion point in a RichTextEdit control.

Applies to
DataWindow type | Method applies to
--- | ---
PowerBuilder | DataWindow control

Syntax
**PowerBuilder**

integer *rtename*.SelectTextLine ( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>rtename</em></td>
<td>A reference to a DataWindow control. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.</td>
</tr>
</tbody>
</table>

Return value
Returns the number of characters selected if it succeeds and –1 if an error occurs.

Usage
If the RichTextEdit control contains a selection, the insertion point can be at the beginning or end of the selection. The way the text was selected determines the location.

If the user made the selection by dragging toward the end, then calling SelectTextLine selects the line at the end of the selection. If the user dragged back, then SelectTextLine selects the line at the beginning of the selection.

SelectTextLine does not select the line-ending characters (carriage return and linefeed).

**PowerBuilder RichTextEdit control**
You can use the same syntax with a PowerBuilder RichText Edit control. See SelectTextLine in the *PowerScript Reference*.

Examples
This statement selects the current line:

```powerbuilder
    dw_1.SelectTextLine()
```

See also
SelectedText
SelectText
SelectTextAll
SelectTextWord
SelectTextWord

Description
Selects the word containing the insertion point in a RichTextEdit control.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powerbuilder
integer rtename.SelectTextWord()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtename</td>
<td>A reference to a DataWindow control in which you want to select a word. The DataWindow object in the DataWindow control must be a RichTextEdit DataWindow.</td>
</tr>
</tbody>
</table>

Return value
Returns the number of characters selected if it succeeds and –1 if a word cannot be selected or an error occurs.

Usage
A word is any group of alphanumeric characters. A word can include underscores and single quotes but doesn’t include punctuation and special characters such as $ or #.

If punctuation or special characters follow the selected word, they are not selected. If the character after the insertion point is a space, punctuation, special character, or end-of-line mark, `SelectTextWord` does not select anything and returns –1.

**PowerBuilder RichTextEdit control**
You can use the same syntax with a PowerBuilder RichText Edit control. See `SelectTextWord` in the *PowerScript Reference*.

Examples
The following statement selects the word containing the insertion point:

```powerbuilder
dw_1.SelectTextWord()
```

For more examples, see examples for the RichTextEdit control in the *PowerScript Reference*.

- SelectedText
- SelectText
- SelectTextAll
- SelectTextLine
SelectTreeNode

Description
Selects or deselects a TreeView node in a TreeView DataWindow.

Applies to
DataWindow type Method applies to
PowerBuilder DataWindow control

Syntax
PowerBuilder

```powerbuilder
Integer dw_control.SelectTreeNode(long row, long groupLevel, boolean bSelect)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dw_control</td>
<td>A reference to a TreeView-style DataWindow control</td>
</tr>
<tr>
<td>row</td>
<td>The number of the row that belongs to the group</td>
</tr>
<tr>
<td>groupLevel</td>
<td>The TreeView level of the group</td>
</tr>
<tr>
<td>bSelect</td>
<td>Indicates whether the TreeView node is selected or not</td>
</tr>
</tbody>
</table>

Return value
Returns 1 if the SelectTreeNode operation succeeds and one of the following negative values if it fails:
-1 DataWindow is null
-5 One or more of the parameters are invalid
-16 DataWindow is not a TreeView DataWindow

Usage
A TreeView DataWindow has several TreeView nodes that can be selected or deselected. You can use the SelectTreeNode method to select or deselect a TreeView node in a TreeView DataWindow that has a particular TreeView level.

The SelectTreeNode method triggers the TreeNodeSelecting and TreeNodeSelected events with a row argument of –1.

Examples
The following example selects the node specified by the text box values:

```powerbuilder
long row
long level
row=long(sle_row.text)
level=long(sle_level.text)
dw_1.SelectTreeNode(row,level,true)
```
**SetAction**

**Description**

Accepts action and context information about user interaction with the Web DataWindow client control in a Web browser so that generated HTML reflects any requested changes.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

**Syntax**

**Web DataWindow server component**

```
integer dwcomponent.SetAction ( string action, string context )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component.</td>
</tr>
<tr>
<td>action</td>
<td>A string describing an action associated with a button click or method call in a Web DataWindow client control on a Web page. The value of action is stored in a page parameter called HTMLGenObjectName_action.</td>
</tr>
<tr>
<td>context</td>
<td>A string describing the context of action in the Web DataWindow client control. The string is generated by a Web DataWindow script and the value is stored in a page parameter called HTMLGenObjectName_context. The format is not documented and subject to change.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and one of these negative values if an error occurs:

- **-1**  Reloading the current context failed
- **-2**  The action was attempted but it failed
- **-3**  The action could not be performed (for example, the action was InsertRow but the DataWindow has no editable fields for entering new data)
- **-4**  The action was aborted by the HTMLContextApplied event

**Usage**

When the user clicks a button in the Web DataWindow client control, the JavaScript for the control stores the action in a page parameter called HTMLGenObjectName_action, and it stores the context in a page parameter called HTMLGenObjectName_context. These parameters are passed to the page server which uses them to call the SetAction method for the server component.

The SetAction method uses the SetHTMLAction method of the DataWindow.

Call GetLastError and GetLastErrorString to get information about database errors that cause SetAction, Update, Retrieve, and RetrieveEx to return –1.
For information about using the Web DataWindow, see the *DataWindow Programmers Guide*.

**Examples**

This JSP example calls `SetAction` for the server component called `dwGen`:

```java
int retVal;
String dw_1_action = (String)request.getParameter("dw_1_action");
String dw_1_context = (String)request.getParameter("dw_1_context");
if (dw_1_context == null){
    dw_1_context = " ";
}
// Check if we need to perform the action
if (dw_1_action!=null){
    retVal = dwGen.SetAction(dw_1_action, dw_1_context);
    if (retVal < 0 ) {
        out.print("Error on SetAction: "+ retVal + ":<BR>");
        out.print(dwGen.GetLastErrorString()+ "<BR>");
    }
}
```

**See also**

*GetLastError*

*GetLastErrorString*

*SetHTMLAction*

**SetActionCode**

**Description**

Sets the action code for an event in a DataWindow control. The action code determines the action that PowerBuilder takes following the event. The default action code is 0.

**Where to use SetActionCode**

`SetActionCode` is obsolete in PowerBuilder. To return a value, include a `RETURN` statement in the event script using the return codes documented for that event.

For the Web ActiveX, use `SetActionCode` for event return values.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>
**SetActionCode**

**Syntax**

**PowerBuilder**

\[
\text{integer } \text{dwcontrol}.\text{SetActionCode}(\text{ long code })
\]

**Web ActiveX**

\[
\text{number } \text{dwcontrol}.\text{SetActionCode}(\text{ number code })
\]

**Argument** | **Description**
--- | ---
\text{dwcontrol} & A reference to a DataWindow control or child DataWindow.
\text{code} & A value specifying the action you want to take in the DataWindow control. The meaning of the action code depends on the event.

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, `SetActionCode` returns null.

**Usage**

Use `SetActionCode` to change the action that occurs following a DataWindow event. Not all DataWindow events have action codes, only those events that can have different outcomes.

**SetActionCode last statement in script**

Although `SetActionCode` is not required to be the last statement in a script, it may not perform as expected if other statements follow it.

**Examples**

In the ItemChanged event script for \text{dw_Employee}, these statements set the action code in \text{dw_Employee} to reject data that is less than the employee’s age:

\[
\text{integer } a, \text{ age} \\
\text{age} = \text{Integer}(\text{sle_Age.Text}) \\
a = \text{Integer}((\text{dw_Employee.GetText}())) \\
\text{IF } a < \text{ age} \text{ THEN } \text{dw_Employee.SetActionCode(1)}
\]

This example shows a script for the \text{DBError} event script that displays a version of the error message to the user. Because PowerBuilder also displays a message to the user after the event, the script calls `SetActionCode` to set the action code to 1, which suppresses the PowerBuilder error message:

\[
\text{integer } \text{errnum} \\
\text{errnum} = \text{dw_emp.DBErrorCode}() \\
\text{// Show error code and message to the user} \\
\text{MessageBox("Database Error", } & \\
\text{ "Number " } + \text{String(errnum)} + " " + & \\
\text{ \text{dw_emp.DBErrorMessage()}, StopSign!)} \\
\text{// Stop PowerBuilder from displaying its message} \\
\text{dw_emp.SetActionCode(1)}
\]
SetBorderStyle

Description
Sets the border style of a column in a DataWindow control or DataStore.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer dwcontrol.SetBorderStyle ( integer column, border borderstyle )

integer dwcontrol.SetBorderStyle ( string column, border borderstyle )

**Web ActiveX**

number dwcontrol.SetBorderStyle ( number column, number borderstyle )

number dwcontrol.SetBorderStyle ( string column, number borderstyle )

Argument | Description
-----------------|--------------------------------------------------
dwcontrol       | A reference to a DataWindow control, DataStore, or child DataWindow.
column          | The column in which you want to change the border style. Column can be a column number or a column name.
borderstyle     | A value of the Border enumerated datatype (PowerBuilder) or an integer (Web ActiveX) identifying the border style you want to use for the column. For a list of valid values, see Border on page 476.

Return value
Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Examples
This example checks the border of column 2 in dw_emp and, if there is no border, gives it a shadow box border:

Border B3
B3 = dw_emp.GetBorderStyle(2)
IF B3 = NoBorder! THEN &
dw_emp.SetBorderStyle(2, ShadowBox!)

See also
GetBorderStyle
SetBrowser

Description
Specifies the Web browser for which you want to generate optimized HTML.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

**Web DataWindow server component**

```java
string dwcomponent.SetBrowser ( string browsername )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component.</td>
</tr>
<tr>
<td>browsername</td>
<td>A string identifying the browser and version. The value should match the string passed to the Web server in the HTTP header. The corresponding server variable is HTTP_USER_AGENT. Sets the value of the HTMLGen.Browser property for the DataWindow object associated with the server component. For information on recognized browsers, see HTMLGen.property.</td>
</tr>
</tbody>
</table>

Return value
Returns an empty string if successful and the syntax error message from the Modify method if it fails.

Usage
If the DataWindow recognizes the browser identifier, it will generate HTML optimized for that browser. A server-side script can get the browser identifier from the server variable HTTP_USER_AGENT.

This method calls the Modify method of the server component’s DataStore to set the property.

For information about using the Web DataWindow, see the *DataWindow Programmers Guide*.

Examples
This JSP example identifies the current browser for the component called dwGen:

```java
String browser = (String)request.getHeader("User-Agent");
dwGen.SetBrowser(browser);
```

In ASP, you can use the ServerVariables method of the Request object to get the HTTP_USER_AGENT value:

```java
var clientbrowser = Request.ServerVariables("HTTP_USER_AGENT");
dwGen.SetBrowser(clientbrowser);
```
SetChanges

**Description**
Applies changes captured with GetChanges to a DataWindow or DataStore. This method is used primarily in distributed applications.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powershell
long dwcontrol.SetChanges ( blob changeblob {, dwConflictResolution resolution } )
```

**Web ActiveX**

```powershell
number dwcontrol.SetChanges ( string changeblob, number resolution )
```

**Argument | Description**
--- | ---
`dwcontrol` | A reference to a DataWindow control or DataStore.
`changeblob` | A read-only change blob created with GetChanges from which you want to apply changes.
`resolution` (obsolete) | A value of the `dwConflictResolution` enumerated datatype (PowerBuilder) or an integer (Web ActiveX) indicating how conflicts should be resolved:
  - FailOnAnyConflict! (default)
  - AllowPartialChanges!

*This argument is obsolete and will be disabled in a future release.*

**Return value**
Returns one of the following values:

- `1` All changes were applied
- `2` A partial update was successful; conflicting changes were discarded
- `-1` Method failed
**SetChanges**

-2 There is a conflict between the state of the DataWindow changeblob and the state of the DataWindow

-3 Column specifications do not match

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

Use this method in conjunction with GetChanges to synchronize two or more DataWindows or DataStores. GetChanges retrieves data buffers and status flags for changed rows in a DataWindow or DataStore and places this information in a blob. SetChanges then applies the contents of this blob to another DataWindow or DataStore.

**Calling SetChanges when no changes are pending**

GetChanges returns 0 if no changes are pending. This can happen if AcceptText is not called after rows are modified. In this case, calling SetChanges will fail, with a return code of –1.

If you call GetChanges on a DataWindow and apply the data passed in the changeblob argument to another DataWindow using SetChanges, you must call GetChanges on the second DataWindow before you reapply changes to it from the first DataWindow. The GetChanges call on the second DataWindow updates the original timestamp on that DataWindow so that it matches the current timestamp. (You cannot use the Reset, ResetUpdate, or AcceptText calls to update the original timestamp.) If you try to reapply changes without first calling GetChanges on the second DataWindow, you will get an error due to the conflict between the state of the DataWindow changeblob and the state of the second DataWindow.

**Examples**

The following example is a script for a remote object function. The script uses SetChanges to apply changes made to a DataWindow control on a client to a DataStore on a server. The changes made on the client are contained in a change blob that is passed as an argument to the function. After applying changes to the DataStore, the server updates the database:

```powerbuilder
// Instance variable: datastore ids_datastore
// Function argument: blob ablb_data
long ll_rv

ids_datastore.SetChanges(ablb_data)
ll_rv = ids_datastore.Update()
```

832
SetColumn

Description
Sets the current column in a DataWindow control or DataStore.

SetColumnByColNum
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer `dwcontrol.SetColumn` ( string `column` )
integer `dwcontrol.SetColumn` ( integer `column` )

**Web DataWindow client control and Web ActiveX**

number `dwcontrol.SetColumn` ( string `column` )
number `dwcontrol.SetColumn` ( number `column` )

**Web DataWindow server component**

short `dwcontrol.SetColumn` ( string `column` )
short `dwcontrol.SetColumnByColNum` ( short `column` )

See also

GetChanges
GetFullState
GetStateStatus
SetFullState

```sql
IF ll_rv > 0 THEN
  COMMIT;
ELSE
  ROLLBACK;
END IF
RETURN ll_rv
```
SetColumn

**Argument**  | **Description**  
---|---  
`dwcontrol`  | A reference to a DataWindow control, DataStore, or child DataWindow.  
`column`  | The column you want to make current. Column can be a column number or a column name.  

**Return value**  
Returns 1 if it succeeds and −1 if an error occurs. If `column` is less than 1 or greater than the number of columns, SetColumn fails.  

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.  

**Usage**  
SetColumn moves the cursor to the current column but does not scroll the DataWindow control.  

Only an editable column can be current. (A column is editable when its tab order value is greater than 0.) Do not try to set a noneditable column as the current column.  

**PowerBuilder environment**  
For use with PowerBuilder ListView controls, see SetColumn in the PowerScript Reference.  

**Events**  
SetColumn can trigger these events:  
* ItemChanged  
* ItemError  
* ItemFocusChanged  

**Avoiding infinite loops**  
Never call SetColumn in the ItemChanged, ItemError, or ItemFocusChanged event. Because SetColumn can trigger these events, such a recursive call can cause a stack fault.  

**Examples**  
This statement makes the 15th column in `dw_Employee` the current column:  
```
dw_Employee.SetColumn(15)  
```

834  
PowerBuilder
SetColumnLink

Description: Specifies information used for constructing hyperlinks for data in a column in generated HTML.

Applies to:

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax:

**Web DataWindow server component**

```csharp
string dwcomponent.SetColumnLink ( string columnname, string link, string linkargs, string linktarget )
```

**Argument** | **Description**
---|---
`dwcomponent` | A reference to a Web DataWindow server component.
`columnname` | The name of a column in the DataWindow object associated with the server component whose values you want formatted as hyperlinks in the generated HTML.
`link` | A URL that is the target of a link (HTML A element) generated for each data item in the column.
The URL can include parameters. Additional parameters from `linkargs` may be added when the HTML is generated.
Sets the value of the HTML.Link property.
`linkargs` | A string in the form:
```plaintext
argname='exp' | argname = 'exp' }
```
`Argname` is an page parameter to be passed to the server.
`Exp` is a DataWindow expression that is evaluated, and whose value is converted using URL encoding and included in the string.
The evaluated `linkargs` string is appended to URL in `link` when HTML is generated to produce a hyperlink for each data item.
For information on constants and quotation marks in `linkargs` expressions, see SetSelfLink.
Sets the value of the HTML.LinkArgs property.
`linktarget` | The name of a target frame or window for the hyperlink specified in the Link property. The target is included in the HTML element using the HTML TARGET attribute.
You can use `linktarget` to implement a master/detail page design by directing the detail page for a data item to a different window or frame.
If `linktarget` is null or an empty string (""), then no TARGET attribute is generated.
Sets the value of the HTML.LinkTarget property.
SetDetailHeight

**Return value**
Returns an empty string if successful and the syntax error message from the Modify method if it fails.

**Usage**
This method calls the Modify method of the server component’s DataStore to set the property.

For information about using the Web DataWindow, see the *DataWindow Programmers Guide*.

**Examples**
This JavaScript example for a server-side script sets up hyperlinks for data in the empid column. The data links to a detailed employee report in an HTML template called empdetail.stm.

The employee id is passed as a page parameter so the empdetail scripts can use it as a retrieval argument. The column name is specified as the expression. Empid is a numeric column so its value has to be converted to a string for the page parameter value. When the server component generates the HTML, it evaluates empid for each row and includes the data value as the link argument:

```javascript
dwMine.SetColumnLink("empid", "empdetail.stm",
    "pagearg_empid='String(empid)'", "");
```

HTML..property

---

**SetDetailHeight**

**Description**
Sets the height of each row in the specified range to the specified value.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

```powerbuilder
integer dwcontrol.SetDetailHeight ( long startrow, long endrow , long height )
```
Web DataWindow server component

    short dwcontrol.SetDetailHeight ( long startrow, long endrow, long height )

Web ActiveX

    number dwcontrol.SetDetailHeight ( number startrow, number endrow, number height )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore for which you want to set the height of one or more rows in the detail area</td>
</tr>
<tr>
<td>startrow</td>
<td>The first row in the range of rows for which you want to set the height</td>
</tr>
<tr>
<td>endrow</td>
<td>The last row in the range of rows for which you want to set the height</td>
</tr>
<tr>
<td>height</td>
<td>The height of the detail area for the specified rows in the units specified for the DataWindow object</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Call SetDetailHeight in a script to vary the amount of space assigned to rows in a DataWindow control or DataStore. You cannot specifically set the height for different rows when you define a DataWindow object in the DataWindow painter, although you can turn on the Autosize Height property for the detail band so that the height of each row is determined by the data.

You can set the detail height of one or more rows to zero, which hides them from view.

Examples

This statement sets the height of rows 2 and 3 to 500:

    dw_1.SetDetailHeight(2, 3, 500)

This script retrieves rows for a DropDownListDataWindow associated with the Company_Name column. It then hides rows 2 and 3 of the DropDownListDataWindow by setting their detail height to 0:

    DataWindowChild dwc;
    integer rtncode;

    rtncode = dw_1.GetChild("company_name", dwc)
    IF rtncode < 0 THEN HALT

    dwc.SetTransObject(SQLCA)
    dwc.Retrieve( )
    dwc.SetDetailHeight(2, 3, 0)
SetDWOObject

**Description**
Specifies the DataWindow library and object that the Web DataWindow server component will use for generating HTML.

**SetDWOObjectEx**
A separate method name is provided as an alternative syntax for specifying DataWindow objects in a PBD generated by the Web DataWindow Component project wizard. Because it is already included in its own library list property, the PBD component does not take an argument for a source file name. The generated PBD also includes a reference to the DataWindow HTML generator that it implements as an interface.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

**Syntax**

**Web DataWindow server component**

```powershell
int dwcomponent.SetDWOObject ( string sourcefile,
                                 string dwobjectname )
int dwcomponent.SetDWOObjectEx ( string dwobjectname )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component.</td>
</tr>
<tr>
<td>sourcefile</td>
<td>The name of a PowerBuilder library (PBL) or dynamic library (PBD) containing DataWindow object definitions or A source definition file (SRD) or A Powersoft report (PSR) containing a DataWindow object definition and data. The file must be located in the file system of the machine hosting the server component.</td>
</tr>
<tr>
<td>dwobjectname</td>
<td>When sourcefile is a PBL or PBD, the name of a DataWindow object in the library. When sourcefile is a PSR or SRD, dwobjectname should be an empty string (“”).</td>
</tr>
</tbody>
</table>

**Return value**
Returns 1 if it succeeds and –1 if an error occurs.

**Usage**
For information about using the Web DataWindow, see the *DataWindow Programmers Guide*. 838 PowerBuilder
Examples

This example identifies the library and DataWindow object for the server component called dwGen:

```java
int retVal = dwGen.SetDWObject("htgenex.pbl", "d_tabular_dept")
```

SetAction

---

### SetFilter

**Description**

Specifies filter criteria for a DataWindow control or DataStore.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```java
integer dwcontrol.SetFilter( string format )
```

**Web DataWindow server component**

```java
short dwcontrol.SetFilter( string format )
```

**Web ActiveX**

```java
number dwcontrol.SetFilter( string format )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the DataWindow control, DataStore, or child DataWindow in which you want to define the filter.</td>
</tr>
<tr>
<td>format</td>
<td>A string whose value is a boolean expression that you want to use as the filter criteria. The expression includes column names or numbers. A column number must be preceded by a pound sign (#). If format is null, PowerBuilder prompts you to enter a filter.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If no DataWindow object has been assigned to the DataWindow or DataStore, SetFilter returns –1. The return value is usually not used.
**Usage**

A DataWindow object can have filter criteria specified as part of its definition. After data is retrieved, rows that do not meet the criteria are immediately transferred from the primary buffer to the filter buffer.

The `SetFilter` method replaces the existing filter criteria—if any are defined for the DataWindow object—with a new set of criteria. Call the `Filter` method to apply the filter criteria and transfer rows that do not meet the filter criteria to the filter buffer.

The filter expression consists of columns, relational operators, and values against which column values are compared. Boolean expressions can be connected with logical operators `AND` and `OR`. You can also use `NOT`, the negation operator. Use parentheses to control the order of evaluation.

Sample expressions are:

```
item_id > 5
NOT item_id = 5
(NOT item_id = 5) AND customer > "Mabson"
item_id > 5 AND customer = "Smith"
#1 > 5 AND #2 = "Smith"
```

The filter expression is a string and does not contain variables. However, you can build the string in your script using the values of script variables. Within the filter string, string constants must be enclosed in quotation marks (see the examples).

**Dictionary or ASCII order**  By default, PowerBuilder performs comparisons in dictionary order. For example, the following expression shows all the rows in which column 2 begins with A, a, B or b:

```
#2 >= 'a' and #2 < 'c'
```

To perform comparisons in ASCII order, append “\s” to the format string. For example, the following expression shows only rows in which column 2 begins with a or b, because the ASCII values of uppercase letters are lower than the ASCII values of lowercase letters:

```
#2 >= 'a' and #2 < 'c' \s
```

**Number format**  The formatting that you enter for numbers and currency in filter expressions display the same way in any country. Changing the regional settings of the operating system does not modify the formatting displayed for numbers and currency at runtime.
**Escape keyword** If you need to use the `%` or `_` characters as part of the string, you can use the escape keyword to indicate that the character is part of the string. For example, the `_` character in the following filter string is part of the string to be searched for, but is treated as a wildcard:

```
comment LIKE '-%_a15progress%-'
```

The escape keyword designates any character as an escape character (do not use a character that is part of the string you want to match). In the following example, the asterisk (*) character is inserted before the `_` character and designated as an escape character, so that the `_` character is treated as part of the string to be matched:

```
comment like '-%o*_a15progress%- escape -*-' escape '
```

**User-specified filters** To let users specify their own filter expression for a DataWindow control, you can pass a null string to the SetFilter method. PowerBuilder displays its Specify Filter dialog box with the filter expression blank. Then you can call Filter to apply the user’s filter expression to the DataWindow. You cannot pass a null string to the SetFilter method for a DataStore object.

**Removing a filter** To remove a filter, call SetFilter with the empty string ("") for format and then call Filter. The rows in the filter buffer will be restored to the primary buffer and positioned after the rows that already exist in the primary buffer.

**Examples**

This statement defines the filter expression for dw_Employee as the value of format1:

```
dw_Employee.SetFilter(format1)
```

The following statements define a filter expression and set it as the filter for dw_Employee. With this filter, only those rows in which the cust_qty column exceeds 100 and the cust_code column exceeds 30 are displayed. The final statement calls Filter to apply the filter:

```
string DWfilter2
  DWfilter2 = "cust_qty > 100 and cust_code >30"
  dw_Employee.SetFilter(DWfilter2)
  dw_Employee.Filter()
```

The following statements define a filter so that emp_state of dw_Employee displays only if it is equal to the value of var1 (in this case ME for Maine). The filter expression passed to SetFilter is emp_state = ME:

```
string Var1
  Var1 = "ME"
  dw_Employee.SetFilter("emp_state = '"+% var1 +"'")
```
The following statements define a filter so that column 1 must equal the value in min_qty and column 2 must equal the value in max_qty to pass the filter. The resulting filter expression is:

\[#1=100 \text{ and } #2=1000\]

The sample code is:

```powershell
integer max_qty, min_qty
min_qty = 100
max_qty = 1000
dw_inv.SetFilter("#1=" + String(min_qty) & 
  + " and #2=" + String(max_qty))
```

The following example sets the filter expression to null, which causes PowerBuilder to display the Specify Filter dialog box. Then it calls Filter, which applies the filter expression the user specified:

```powershell
string null_str
SetNull(null_str)
dw_main.SetFilter(null_str)
dw_main.Filter()
```

See also Filter

---

### SetFormat

**Description**

Specifies a display format for a column in a DataWindow control or DataStore.

**SetFormatByColNum**

A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

```powershell
integer dwcontrol.SetFormat ( string column, string format )
integer dwcontrol.SetFormat ( integer column, string format )
```
CHAPTER 9  Methods for the DataWindow Control

Web DataWindow server component

short dwcontrol.SetFormat ( string column, string format )
short dwcontrol.SetFormatByColNum ( short column, string format )

Web ActiveX

number dwcontrol.SetFormat ( string column, string format )
number dwcontrol.SetFormat ( number column, string format )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>column</td>
<td>The column for which you are specifying the display format. Column can be a column number or a column name.</td>
</tr>
<tr>
<td>format</td>
<td>A string whose value is the display format for the DataWindow column.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and –1 if an error occurs. The return value is usually not used.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

For information on valid display formats for different datatypes, see the Users Guide.

If you are specifying the display format for a number, the format must use U.S. notation. For example, comma (,) represents the thousands delimiter and period (.) represents the decimal place. At runtime, the locally correct symbols will be displayed.

An EditMask edit style supersedes any display format applied to the column. When the column has an EditMask edit style, calling SetFormat has no effect.

Examples

These statements define the display format for column 15 of dw_employee to the contents of format1:

```plaintext
string format1
format1 = "#$,##0.00"
dw_employee.SetFormat(15, format1)
```

See also

GetFormat
SetFullState

Description
Applies the contents of a DataWindow blob retrieved by GetFullState to a DataWindow or DataStore.

This method is used primarily in distributed applications.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
long dwcontrol.SetFullState ( blob dwasblob )
```

**Web ActiveX**

```powershell
number dwcontrol.SetFullState ( string dwasblob )
```

Argument | Description
----------|-----------------------------
`dwcontrol` | A reference to a DataWindow control or DataStore
`dwasblob` | A blob that contains the state information you want to apply to the DataWindow control or DataStore

Return value

Returns –1 if an error occurs and one of the following values if it succeeds:

1. DataWindow objects match; old data and state overwritten.
2. DataWindow objects do not match; old object, data, and state replaced.
3. No DataWindow object associated with DataWindow control or DataStore; the DataWindow object associated with the blob is used. The value of the DataObject property remains an empty string.

**Null** If any argument’s value is null in PowerBuilder or JavaScript, the method returns null.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

GetFullState retrieves the entire state of a DataWindow or DataStore into a blob, including the DataWindow object specification, the data buffers, and the status flags. When you use SetFullState to apply the blob created by GetFullState to another DataWindow, the target DataWindow has enough information to recreate the source DataWindow.
Because the blob created by GetFullState contains the DataWindow object specification, a subsequent call to SetFullState will overwrite the DataWindow object for the target DataWindow control or DataStore. If the target of SetFullState does not have a DataWindow object associated with it, the DataWindow object associated with the blob is used. The value of the DataObject property remains null.

When you use GetFullState and SetFullState to synchronize a DataWindow control on a client with a DataStore on a server, you need to make sure that the DataWindow object for the DataStore contains the presentation style you want to display on the client.

**Limitation on calling SetFullState from the current DataWindow**
SetFullState destroys the referenced DataWindow and creates a new one using the contents of the DataWindow blob that you specify as an argument to SetFullState. If you call SetFullState from an event in the current DataWindow, the DataWindow is destroyed before the event code can be completed and you might cause the application to crash. Therefore you should never use the “this” pronoun when calling SetFullState.

**Examples**
These statements in a distributed client application call a remote object function that retrieves database information into a DataStore and puts the contents of the DataStore into a blob by using GetFullState. After the server passes the blob back to the client, the client uses SetFullState to apply the blob to a DataWindow control:

```csharp
// Global variable: connection myconnect
// Instance variable: uo_employee iuo_employee

blob lblb_data
long ll_rv

myconnect.CreateInstance(iuo_employee)
iuo_employee.RetrieveData(lblb_data)

ll_rv = dw_empdata.SetFullState(lblb_data)

IF ll_rv = -1 THEN
    MessageBox("Error", "SetFullState failed!")
END IF
```

**See also**
GetChanges
GetFullState
GetStateStatus
SetChanges
SetHTMLAction

Description

Accepts action and context information about user interaction with the Web DataWindow client control in a Web browser so that newly generated HTML can reflect any requested changes.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
integer dwcontrol.SetHTMLAction ( string action, string context )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td><code>action</code></td>
<td>A string describing an action associated with a button click or method call in a Web DataWindow client control on a Web page. The value is stored in a page parameter called <code>HTMLGenObjectName_action</code>. <code>action</code> must be a valid action and cannot be an empty string or the value none.</td>
</tr>
<tr>
<td><code>context</code></td>
<td>A string describing the context of <code>action</code> in the Web DataWindow client control. The string is generated by a Web DataWindow script and the value is stored in a page parameter called <code>HTMLGenObjectName_context</code>. The format is not documented and subject to change.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and one of these negative values if an error occurs:

-1  Reloading the current context failed.
-2  The action was attempted but it failed.
-3  The action could not be performed (for example, the action was InsertRow but the DataWindow has no editable fields for entering new data).
-4  The action was aborted by the HTMLContextApplied event.
-5  The action is invalid.

Usage

SetHTMLAction triggers the HTMLContextApplied event after restraining the context but before performing the action. You can use the event to perform data validation using methods of a server component.

If you write your own server component in PowerBuilder instead of using the generic Web DataWindow server component, you use this method to update the generated HTML to reflect user actions.
For information about building your own server component, see the DataWindow Programmers Guide.

See also SetAction

SetHTMLObjectName

Description Specifies a name for the Web DataWindow client control.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

Web DataWindow server component

    string dwcomponent.SetHTMLObjectName ( string objectname )

Argument          Description
---------------------------------------------------------------
        dwcomponent A reference to a Web DataWindow server component.
          objectname A string specifying a name used in generated code for the Web
                         DataWindow client control, page parameters, and client side events.
                         Sets the value of the HTMLGen.ObjectName property for the DataWindow object associated with the server component.

Return value Returns an empty string if successful and the syntax error message from the Modify method if it fails.

Usage

You must specify a unique object name when there will be more than one Web DataWindow on a Web page so names will not conflict.

This method calls the Modify method of the server component’s DataStore to set the property.

For information about using the Web DataWindow, see the DataWindow Programmers Guide.

Examples

This example specifies a name to be used in generated HTML for the server component called webDW:

    webDW.SetHTMLObjectName(“dwMine”);

See also Generate Modify OneTrip HTMLGen.property
SetItem

Description

Sets the value of a row and column in a DataWindow control or DataStore to the specified value.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer \( \text{dwcontrol}.\text{SetItem} \) ( long \( \text{row} \), integer \( \text{column} \), any \( \text{value} \) )

integer \( \text{dwcontrol}.\text{SetItem} \) ( long \( \text{row} \), string \( \text{column} \), any \( \text{value} \) )

**Web DataWindow client control and Web ActiveX**

number \( \text{dwcontrol}.\text{SetItem} \) ( number \( \text{row} \), number \( \text{column} \), variant \( \text{value} \) )

number \( \text{dwcontrol}.\text{SetItem} \) ( number \( \text{row} \), string \( \text{column} \), variant \( \text{value} \) )

Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{dwcontrol} )</td>
<td>The name of the DataWindow control, DataStore, or child DataWindow in which you want to set a specific row and column to a value.</td>
</tr>
<tr>
<td>( \text{row} )</td>
<td>The row location of the data.</td>
</tr>
<tr>
<td>( \text{column} )</td>
<td>The column location of the data. ( \text{Column} ) can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view.</td>
</tr>
<tr>
<td>( \text{value} )</td>
<td>The value to which you want to set the data at the row and column location. The datatype of the value must be the same datatype as the column.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and −1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

SetItem sets a value in a DataWindow buffer. It does not affect the value currently in the edit control over the current row and column, which is the data the user has changed or might change. The value in the edit control does not become the value of the DataWindow item until it is validated and accepted (see AcceptText). In a script, you can change the value in the edit control with the SetText method.
You can use SetItem when you want to set the value of an item in a DataWindow control or DataStore that has script as the source.

**Displaying data in character columns** When you use SetItem (or dot notation) to assign a value to a character column that is defined to have 512 characters or less, the actual size of the column in the DataWindow definition is ignored. If the assigned value has more than 512 characters, the value displayed in the DataWindow is truncated at 512 characters. If the DataWindow column is defined to have more than 512 characters, its size is respected. For example, if the DataWindow column is defined to have 1, 10, or 100 characters, up to 512 characters of the assigned value are displayed. If the DataWindow column is defined to have 1000 characters, up to 1000 characters are displayed.

**Group and TreeView DataWindows** In Group and TreeView DataWindow objects, you must call GroupCalc after you call SetItem to display data correctly.

**Using SetItem in the ItemChanged and ItemError events** In the ItemChanged and ItemError events, you can call SetItem to set the value of an item when the data the user entered is not valid. If you want the user to have an opportunity to enter a different value, after calling SetItem you can callSetText to put that same value in the edit control so that the user sees the value too. In the script, use a return code that rejects the value in the edit control, avoiding further processing, but does not allow the focus to change. To retain focus and display an error message, return 1 for ItemChanged or 0 for ItemError.

When you use a return code that rejects the data the user entered but allows the focus to change (a return code of 2 in the script for the ItemChanged event or 3 in the ItemError event), you do not need to call SetText because the value set with SetItem displays.

If PowerBuilder cannot properly convert the string the user entered, you must include statements in the script for the ItemChanged or ItemError event to convert the data and use SetItem with the converted data. For example, if the user enters a number with commas and a dollar sign (for example, $1,000), PowerBuilder is unable to convert the string to a number and you must convert it in the script.

**PowerBuilder environment** For use with PowerBuilder ListView and TreeView controls, see SetItem in the PowerScript Reference.

**Examples**

This statement sets the value of row 3 of the column named hire_date of the DataWindow control dw_order to 2003-06-07:
When a user starts to edit a numeric column and leaves it without entering any data, PowerBuilder tries to assign an empty string to the column. This fails the datatype validation test. In this example, code in the ItemError event sets the column’s value to null and allows the focus to change.

This example assumes that the datatype of column 2 is numeric. If it is date, time, or datetime, replace the first line (integer null_num) with a declaration of the appropriate datatype:

```powershell
integer null_num //to contain null value
SetNull(null_num)
```

// Special processing for column 2
IF dwo.ID = 2 THEN
  // If user entered nothing (""), set to null
  IF data = "" THEN
    This.SetItem(row, dwo.ID, null_num)
    RETURN 2
  END IF
END IF

The following example is a script for a DataWindow’s ItemError event. If the user specifies characters other than digits for a numeric column, the data will fail the datatype validation test. You can include code to strip out characters such as commas and dollar signs and use SetItem to assign the now valid numeric value to the column. The return code of 3 causes the data in the edit control to be rejected because the script has provided a valid value:

```powershell
string snum, c
integer cnt

// Extract the digits from the user's data
FOR cnt = 1 to Len(data)
  c = Mid(data, cnt, 1) // Get character
  IF IsNumber(c) THEN snum = snum + c
NEXT
This.SetItem(row, dwo.ID, Long(snum))
RETURN 3
```

See also
- GetItemDate
- GetItemDateTime

- GetItemTime
CHAPTER 9 Methods for the DataWindow Control

GetText
SetText

### SetItemDate

**Description**
Sets the value of a row and column in a DataWindow control to the specified value.

**SetItemDateByColNum**
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component (see SetItem for equivalent client control method)</td>
</tr>
</tbody>
</table>

**Syntax**

**Web DataWindow server component**

```
short dwcontrol.SetItemDate ( long row, string column, string value )
short dwcontrol.SetItemDateByColNum ( long row, short column, string value )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the Web DataWindow control in which you want to set a specific row and column to a value.</td>
</tr>
<tr>
<td>row</td>
<td>The row location of the data.</td>
</tr>
<tr>
<td>column</td>
<td>The column location of the data. Column can be a column number or a column name.</td>
</tr>
<tr>
<td>value</td>
<td>The value to which you want to set the data at the row and column location.</td>
</tr>
</tbody>
</table>

**Usage**

Although JavaScript does not distinguish between the Date, DateTime, and Time datatypes, the DataStore will give an error if the wrong type is passed. You can use the SetItemDateByColNum method to set values in columns with the DateTime and Time datatypes.

Because the Web DataWindow server component does not support overloading, you must use the SetItemDateByColNum variant instead of the standard SetItemDate method when you want to refer to the column by number.
**SetItemDateTime**

**Description**
Sets the value of a row and column in a DataWindow control to the specified value.

**SetItemDateTimeByColNum**
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**
- **DataWindow type**: Web
- **Method applies to**: Server component (see SetItem for equivalent client control method)

**Syntax**

**Web DataWindow server component**

\[ \text{short } \text{dwcontrol}.\text{SetItemDateTime} \left( \text{long } \text{row}, \text{string } \text{column}, \text{string } \text{value} \right) \]

\[ \text{short } \text{dwcontrol}.\text{SetItemDateTimeByColNum} \left( \text{long } \text{row}, \text{short } \text{column}, \text{string } \text{value} \right) \]

<table>
<thead>
<tr>

<tbody>
<tr>
<td>\text{dwcontrol}</td>
<td>The name of the Web DataWindow control in which you want to set a specific row and column to a value.</td>
</tr>
<tr>
<td>\text{row}</td>
<td>The row location of the data.</td>
</tr>
<tr>
<td>\text{column}</td>
<td>The column location of the data. Column can be a column number or a column name.</td>
</tr>
<tr>
<td>\text{value}</td>
<td>The value to which you want to set the data at the row and column location.</td>
</tr>
</tbody>
</table>

**Usage**
Although JavaScript does not distinguish between the Date, DateTime, and Time datatypes, the DataStore will give an error if the wrong type is passed. You can use the SetItemDate and SetItemTime methods to set values in columns with the Date and Time datatypes.
Because the Web DataWindow server component does not support overloading, you must use the `SetItemDateTimeByColNum` variant instead of the standard `SetItemDateTime` method when you want to refer to the column by number.

See also
- `SetItem`
- `SetItemDate`
- `SetItemTime`

**SetItemNumber**

Description
- Sets the value of a row and column in a DataWindow control to the specified value.

**SetItemNumberByColNum**
- A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component (see SetItem for equivalent client control method)</td>
</tr>
</tbody>
</table>

**Syntax**

**Web DataWindow server component**

- `short dwcontrol.SetItemNumber ( long row, string column, double value )`
- `short dwcontrol.SetItemNumberByColNum ( long row, short column, double value )`

**Argument Table**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>The name of the Web DataWindow control in which you want to set a specific row and column to a value.</td>
</tr>
<tr>
<td><code>row</code></td>
<td>The row location of the data.</td>
</tr>
<tr>
<td><code>column</code></td>
<td>The column location of the data. Column can be a column number or a column name.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>The value to which you want to set the data at the row and column location.</td>
</tr>
</tbody>
</table>
**SetItemStatus**

**Usage**
Because the Web DataWindow server component does not support overloading, you must use the `SetItemNumberByColNum` variant instead of the standard `SetItemNumber` method when you want to refer to the column by number.

**See also**
SetItem

---

**SetItemStatus**

**Description**
Changes the modification status of a row or a column within a row. The modification status determines the type of SQL statement the Update method will generate for the row.

---

**SetItemStatusByColNum**
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

---

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

- `integer dwcontrol.SetItemStatus ( long row, integer column, dwbuffer dwbuffer, dwitemstatus status )`
- `integer dwcontrol.SetItemStatus ( long row, string column, dwbuffer dwbuffer, dwitemstatus status )`

**Web DataWindow server component**

- `short dwcontrol.SetItemStatus ( long row, string column, string dwbuffer, string status )`
- `short dwcontrol.SetItemStatusByColNum ( long row, short column, string dwbuffer, string status )`

**Web ActiveX**

- `number dwcontrol.SetItemStatus ( number row, number column, number dwbuffer, number status )`
- `number dwcontrol.SetItemStatus ( number row, string column, number dwbuffer, number status )`
**CHAPTER 9 Methods for the DataWindow Control**

**Argument Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td><code>row</code></td>
<td>The row location in which you want to set the status.</td>
</tr>
<tr>
<td><code>column</code></td>
<td>The column location in which you want to set the status. <em>Column</em> can be a column number or a column name. To set the status for the row, enter 0 for <code>column</code>.</td>
</tr>
<tr>
<td><code>dwbuffer</code></td>
<td>A value identifying the DataWindow buffer that contains the row. For a list of valid values, see DWBuffer on page 478.</td>
</tr>
<tr>
<td><code>status</code></td>
<td>A value of the <code>dwItemStatus</code> enumerated datatype (PowerBuilder) or an integer (Web ActiveX) or a string (Web DataWindow) specifying the new status. For a list of valid values, see DWItemStatus on page 479.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

**How statuses are set** There are four DataWindow item statuses, two of which apply only to rows:

**Table 9-7: Possible statuses for DataWindow items**

<table>
<thead>
<tr>
<th>Status</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>New!</td>
<td>Rows</td>
</tr>
<tr>
<td>NewModified!</td>
<td>Rows</td>
</tr>
<tr>
<td>NotModified!</td>
<td>Rows and columns</td>
</tr>
<tr>
<td>DataModified!</td>
<td>Rows and columns</td>
</tr>
</tbody>
</table>

**When data is retrieved** When data is retrieved into a DataWindow, all rows and columns initially have a status of NotModified!.

After data has changed in a column in a particular row, either because the user changed the data or the data was changed programmatically, such as through the `setItem` method, the column status for that column changes to DataModified!. Once the status for any column in a retrieved row changes to DataModified!, the row status also changes to DataModified!.

**When rows are inserted** When a row is inserted into a DataWindow, it initially has a row status of New!, and all columns in that row initially have a column status of NotModified!. After data has changed in a column in the row, either because the user changed the data or the data was changed programmatically, such as through the `setItem` method, the column status changes to DataModified!. Once the status for any column in the inserted row changes to DataModified!, the row status changes to NewModified!. 
When a DataWindow column has a default value, the column’s status does not change to DataModified! until the user makes at least one actual change to a column in that row.

**When Update is called** A row’s status flag determines what SQL command the Update method uses to update the database. INSERT or UPDATE is called, depending upon the following row statuses:

<table>
<thead>
<tr>
<th>Row status</th>
<th>SQL statement generated</th>
</tr>
</thead>
<tbody>
<tr>
<td>NewModified!</td>
<td>INSERT</td>
</tr>
<tr>
<td>DataModified!</td>
<td>UPDATE</td>
</tr>
</tbody>
</table>

A column is included in an UPDATE statement only if the following two conditions are met:

- The column is on the updatable column list maintained by the DataWindow object
  
  For more information about setting the update characteristics of the DataWindow object, see the *Users Guide*.

- The column has a column status of DataModified!

The DataWindow control includes all columns in INSERT statements it generates. If a column has no value, the DataWindow attempts to insert a null. This causes a database error if the database does not allow nulls in that column.

**Changing statuses using SetItemStatus** Use SetItemStatus when you want to change the way a row will be updated. Typically, you do this to prevent the default behavior from taking place. For example, you might copy a row from one DataWindow to another. After the user modifies the row, you want to issue an UPDATE statement instead of an INSERT statement.

**Changing column status** You use SetItemStatus to change the column status from DataModified! to NotModified!, or the converse.

**Change column status when you change row status** Changing the row status changes the status of all columns in that row to NotModified!, so if the Update method is called, no SQL update is produced. You must change the status of columns to be updated after you change the row status.
CHAPTER 9  Methods for the DataWindow Control

Changing row status  Changing row status is a little more complicated. The following table illustrates the effect of changing from one row status to another:

Table 9-9: Effect of changing from one row status to another

<table>
<thead>
<tr>
<th>Original status</th>
<th>Specified status</th>
<th>Data Modified!</th>
<th>Not Modified!</th>
</tr>
</thead>
<tbody>
<tr>
<td>—</td>
<td>New!</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>New!</td>
<td>-</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>NewModified!</td>
<td>No</td>
<td>-</td>
<td>Yes</td>
</tr>
<tr>
<td>DataModified!</td>
<td>NewModified!</td>
<td>Yes</td>
<td>-</td>
</tr>
<tr>
<td>NotModified!</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

In the table, Yes means the change is valid. For example, issuing SetItemStatus on a row that has the status NotModified! to change the status to New! does change the status to New!. No means that the change is not valid and the status is not changed.

Issuing SetItemStatus to change a row status from NewModified! to NotModified! actually changes the status to New!. Issuing SetItemStatus to change a row status from DataModified! to New! actually changes the status to NewModified!.

Changing a row’s status to NotModified! or New! causes all columns in that row to be assigned a column status of NotModified!. Change the column’s status to DataModified! to ensure that an update results in a SQL UPDATE.

Changing status indirectly  When you cannot change to the desired status directly, you can usually do it indirectly. For example, change New! to DataModified! to NotModified!.

Resetting status for the whole DataWindow object  To reset the update status of the entire DataWindow object, use the ResetUpdate method. This sets all status flags to NotModified! except for New! status flags, which remain unchanged.
SetItemString

Examples

This statement sets the status of row 5 in the Salary column of the primary buffer of `dw_history` to `NotModified!`:

```
dw_history.SetItemStatus(5, "Salary", &Primary!, NotModified!)
```

This statement sets the status of row 5 in the `emp_status` column of the primary buffer of `dw_new_hire` to `DataModified!`:

```
dw_new_hire.SetItemStatus(5, "emp_status", &Primary!, DataModified!)
```

This code sets the status of row 5 in the primary buffer of `dw_rpt` to `DataModified!` if its status is currently `NewModified!`:

```
dwItemStatus l_status
l_status = dw_rpt.GetItemStatus(5, 0, Primary!)
IF l_status = NewModified! THEN
   dw_rpt.SetItemStatus(5, 0, Primary!, DataModified!)
END IF
```

See also

GetItemStatus
ResetUpdate

SetItemString

Description

Sets the value of a row and column in a DataWindow control to the specified value.

SetItemStringByColNum

A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component (see SetItem for equivalent client control method)</td>
</tr>
</tbody>
</table>

Syntax

**Web DataWindow server component**

```
short dwcontrol.SetItemString ( long row, string column, string value )
short dwcontrol.SetItemStringByColNum ( long row, short column, string value )
```
Because the Web DataWindow server component does not support overloading, you must use the SetItemStringByColNum variant instead of the standard SetItemString method when you want to refer to the column by number.

See also  SetItem

SetItemTime

Sets the value of a row and column in a DataWindow control to the specified value.

SetItemTimeByColNum

A separate method name, SetItemTimeByColNum, is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Apply to

DataWindow type Method applies to
Web Server component (see SetItem for equivalent client control method)

Syntax

Web DataWindow server component

short dwcontrol.SetItemTime ( long row, string column, string value )
short dwcontrol.SetItemTimeByColNum ( long row, short column, string value )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the Web DataWindow control in which you want to set a specific row and column to a value.</td>
</tr>
<tr>
<td>row</td>
<td>The row location of the data.</td>
</tr>
<tr>
<td>column</td>
<td>The column location of the data. Column can be a column number or a column name.</td>
</tr>
<tr>
<td>value</td>
<td>The value to which you want to set the data at the row and column location.</td>
</tr>
</tbody>
</table>
SetPageSize

**SetPageSize**

Specifies the number of rows to include in a generated Web page for the Web DataWindow.

**Description**

- **DataWindow type**
  - **Method applies to**: Server component

**Syntax**

```plaintext
string dwcomponent.SetPageSize ( long pagesize )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component.</td>
</tr>
<tr>
<td>pagesize</td>
<td>The number of rows of data to include in a generated Web page. If the Web page does not include all available rows, you can include Button controls in the DataWindow object for navigating other subsets of rows. To include all available rows in the page, specify 0 for PageSize. Sets the value of the HTMLGen.PageSize property for the DataWindow object associated with the server component.</td>
</tr>
</tbody>
</table>
CHAPTER 9  Methods for the DataWindow Control

Return value
Returns an empty string if successful and the syntax error message from the Modify method if it fails.

Usage
This method calls the Modify method of the server component’s DataStore to set the property. It is particularly useful for the XML Web DataWindow where you typically want to limit the number of rows per page.

For information about using the Web DataWindow, see the DataWindow Programmers Guide.

Examples
This example specifies that the HTML generated by the webDW component will have 20 rows of data:

```
webDW.SetPageSize(20);
```

See also
Generate
Modify
HTMLGen.property

SetPosition

Description
Moves a control within the DataWindow to another band or changes the front-to-back order of controls within a band.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>
SetPosition

Syntax

**PowerBuilder**

```powershell
integer dwcontrol.SetPosition( string controlname, string band ,
boolean bringtofront )
```

**Web DataWindow server component**

```powershell
short dwcontrol.SetPosition( string controlname, string band, boolean bringtofront )
```

**Web ActiveX**

```powershell
number dwcontrol.SetPosition( string controlname, string band, boolean bringtofront )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td>controlname</td>
<td>The name of the control within the DataWindow that you want to move. You assign names to the controls in the DataWindow painter.</td>
</tr>
<tr>
<td>band</td>
<td>A string whose value is the name of the band or layer in which you want to position <code>controlname</code>. Layer names are background and foreground. Band names are detail, header, footer, summary, header.#, and trailer.#, where # is the group level number. Enter the empty string (&quot;&quot;&quot;) if you do not want to change the band.</td>
</tr>
</tbody>
</table>
| bringtofront| A boolean indicating whether you want to bring `controlname` to the front within the band:  
  - True – Bring it to the front.  
  - False – Do not bring it to the front. |

Return value

Returns 1 when it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

**PowerBuilder environment**

For setting the position of controls in the front-to-back order of a PowerBuilder window, see SetPosition in the **PowerScript Reference**.

Examples

This statement moves oval_red in dw_rpt to the header and brings it to the front:

```powershell
dw_rpt.SetPosition("oval_red", "header", true)
```

This statement does not change the position of oval_red, but does bring it to the front:

```powershell
dw_rpt.SetPosition("oval_red", ",", true)
```

This statement moves oval_red to the footer, but does not bring it to the front:

```powershell
dw_rpt.SetPosition("oval_red", "footer", false)
```
## SetRedraw

**Description**
Controls the automatic redrawing of an object or control after each change to its properties.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
inget ostreamname.SetRedraw ( boolean redraw )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectname</td>
<td>The name of the object or control for which you want to change the redraw setting.</td>
</tr>
</tbody>
</table>
| redraw | A boolean value that controls whether PowerBuilder redraws an object automatically after a change. Values are:  
  * True – Automatically redraw the object or control after each change to its properties.  
  * False – Do not redraw after each change. |

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If `redraw` is null, `SetRedraw` returns null.

**Usage**
By default, PowerBuilder redraws a control after each change to properties that affect appearance. Use `SetRedraw` to turn off redrawing temporarily in order to avoid flicker and reduce redrawing time when you are making several changes to the properties of an object or control. If the window is not visible, `SetRedraw` fails.

**PowerBuilder environment**
Inherited from DragObject. For more details on use with PowerBuilder objects, see `SetRedraw` in the *PowerScript Reference*.

## SetRichTextAlign

**Description**
Sets the alignment value to use while editing columns with the RichText edit style.

**Applies to**
DataWindow control
SetRichTextColor

Syntax

Integer dwcontrol.SetRichTextColor ( long color )

Argument | Description
--- | ---
dwcontrol | A reference to the DataWindow control
sAlign | Value for specifying the alignment that you want to set for columns with the RichText edit style. Allowable values are:

- Left!
- Right!
- Center!
- Justified!

Return value

Returns 0 if it succeeds and –1 if an error occurs. If the argument’s value is null, SetRichTextColor returns null.

- 0 Success
- -1 No RichText column is being edited

Usage

You can call this method from a button in a custom toolbar that you use to set display characteristics of columns with the RichText edit style.

Examples

This example sets the alignment value for editing columns that have a RichText edit style:

```
Integer ll_temp
Alignment l_align
l_align = Right!
ll_temp = dw_1.SetRichTextColor(l_align)
```

See also

GetRichTextColor
SetRichTextColor
SetRichTextFaceName
SetRichTextSize
SetRichTextStyle

SetRichTextColor

Description

Sets the color to use while editing columns with the RichText edit style.

Applies to

DataWindow control

Syntax

Integer dwcontrol.SetRichTextColor ( long color )
### SetRichTextColor

**Description**
Sets the color for columns with the RichText edit style.

**Applies to**
DataWindow control

**Syntax**

```plaintext
Integer dwcontrol.SetRichTextColor ( Long color )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td><code>color</code></td>
<td>A long value specifying the color that you want to set for editing columns with the RichText edit style</td>
</tr>
</tbody>
</table>

**Return value**
Returns 0 if it succeeds and –1 if an error occurs. If the argument’s value is null, `SetRichTextColor` returns null.

- 0  Success
- -1  No RichText column is being edited

**Usage**
If the color for columns with the RichText edit style is white, background transparency and gradient and text transparency will not work properly.

You can call this method from a button in a custom toolbar that you use to set display characteristics of columns with the RichText edit style.

**Examples**
This example sets green as the current color to use for editing columns that have a RichText edit style:

```plaintext
Integer l_rtn
Long l_color
l_color = RGB(0, 255, 0)
l_rtn = dw_1.SetRichTextColor(l_color)
```

**See also**

- GetRichTextColor
- SetRichTextAlign
- SetRichTextFaceName
- SetRichTextSize
- SetRichTextStyle

### SetRichTextAlign

**Description**
Sets the text alignment for columns with the RichText edit style.

**Applies to**
DataWindow control

**Syntax**

```plaintext
Integer dwcontrol.SetRichTextAlign ( String typeface )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td><code>typeface</code></td>
<td>A string value for the typeface that you want to set for editing columns with the RichText edit style</td>
</tr>
</tbody>
</table>

### SetRichTextFaceName

**Description**
Sets the typeface to use while editing columns with the RichText edit style.

**Applies to**
DataWindow control

**Syntax**

```plaintext
Integer dwcontrol.SetRichTextFaceName ( String typeface )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td><code>typeface</code></td>
<td>A string value for the typeface that you want to set for editing columns with the RichText edit style</td>
</tr>
</tbody>
</table>

### SetRichTextSize

**Description**
Sets the font size for columns with the RichText edit style.

**Applies to**
DataWindow control

**Syntax**

```plaintext
Integer dwcontrol.SetRichTextSize ( Integer size )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td><code>size</code></td>
<td>An integer value specifying the font size that you want to set for editing columns with the RichText edit style</td>
</tr>
</tbody>
</table>

### SetRichTextStyle

**Description**
Sets the text style for columns with the RichText edit style.

**Applies to**
DataWindow control

**Syntax**

```plaintext
Integer dwcontrol.SetRichTextStyle ( String style )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td><code>style</code></td>
<td>A string value for the text style that you want to set for editing columns with the RichText edit style</td>
</tr>
</tbody>
</table>

**Examples**
This example sets the text style for columns with the RichText edit style:

```plaintext
Integer l_rtn
Long l_size
l_size = 12
l_rtn = dw_1.SetRichTextSize(l_size)
```
SetRichTextSize

**Description**
Sets the size of the font to use while editing columns with the RichText edit style.

**Applies to**
DataWindow control

**Syntax**
```
Integer dwcontrol.SetRichTextSize ( long size )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td>size</td>
<td>A long value for the point size of the font that you want to set for editing columns with the RichText edit style</td>
</tr>
</tbody>
</table>

**Return value**
Returns 0 if it succeeds and –1 if an error occurs. If the argument’s value is null, SetRichTextSize returns null.

0 Success
-1 No RichText column is being edited

**Usage**
You can call this method from a button in a custom toolbar that you use to set display characteristics of columns with the RichText edit style.

**Examples**
This example sets Arial as the current typeface to use for editing columns that have a RichText edit style:

```
Integer li_rtn
li_rtn = dw_1.SetRichTextFaceName("Arial")
```

See also
GetRichTextFaceName
SetRichTextAlign
SetRichTextColor
SetRichTextSize
SetRichTextStyle
Examples

This example sets 16 as the current point size to use for editing columns that have a RichText edit style:

```
Integer li_rtn
li_rtn = dw_1.SetRichTextSize(16)
```

See also

GetRichTextSize
SetRichTextAlign
SetRichTextColor
SetRichTextFaceName
SetRichTextStyle

---

**SetRichTextStyle**

**Description**

Sets the style of the font to use while editing columns with the RichText edit style.

**Applies to**

DataWindow control

**Syntax**

```
Integer dwcontrol.SetRichTextStyle ( boolean bold, boolean underline, boolean italic, boolean strikeout, )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control</td>
</tr>
<tr>
<td>bold</td>
<td>A boolean for the bold style</td>
</tr>
<tr>
<td>underline</td>
<td>A boolean for the underlined style</td>
</tr>
<tr>
<td>italic</td>
<td>A boolean for the italic style</td>
</tr>
<tr>
<td>strikeout</td>
<td>A boolean for the strikeout style</td>
</tr>
</tbody>
</table>

**Return value**

Returns 0 if it succeeds and –1 if an error occurs. If the argument’s value is null, SetRichTextStyle returns null.

<table>
<thead>
<tr>
<th>Success</th>
<th>-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No RichText column is being edited</td>
</tr>
</tbody>
</table>

**Usage**

You can call this method from a button in a custom toolbar that you use to set display characteristics of columns with the RichText edit style.
**SetRow**

**Examples**

This example sets an underlined, bolded font as the current font for editing columns with a RichText edit style:

```powerbuilder
Integer li_rtn
li_rtn = dw_1.SetRichTextStyle(true, false, false, &false)
```

**See also**

GetRichTextStyle
SetRichTextAlign
SetRichTextColor
SetRichTextFaceName
SetRichTextSize

## SetRow

**Description**

Sets the current row in a DataWindow control or DataStore.

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

### Syntax

**PowerBuilder**

```powerbuilder
type dwcontrol
integer dwcontrol.SetRow ( long row )
```

**Web DataWindow client control and Web ActiveX**

```powerbuilder
type dwcontrol
number dwcontrol.SetRow ( number row )
```

**Web DataWindow server component**

```powerbuilder
type dwcontrol
short dwcontrol.SetRow ( long row )
```

### Argument | Description
--- | ---
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow in which you want to set the current row
`row` | The row you want to make current

### Return value

Returns 1 if it succeeds and −1 if an error occurs. If `row` is less than 1 or greater than the number of rows, SetRow fails.

If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.
**SetRow** moves the cursor to the current row but does not scroll the DataWindow control or DataStore.

**Events**  
SetRow can trigger these events:
- ItemChanged
- ItemError
- ItemFocusChanged
- RowFocusChanged

**Avoiding infinite loops**

Never call SetRow in the ItemChanged event or any of the other events listed above. Because SetRow can trigger these events, such a recursive call can cause a stack fault.

**Examples**

This statement sets the current row in dw_employee to 15:

```powerbuilder
dw_employee.SetRow(15)
```

This example unhighlights all highlighted rows, if any. It then sets the current row to 15 and highlights it. If row 15 is not visible, you can use ScrollToRow instead of SetRow:

```powerbuilder
dw_employee.SelectRow(0, false)
dw_employee.SetRow(15)
dw_employee.SelectRow(15, true)
```

**See also**

GetColumn  
GetRow  
SetColumn  
SetRowFocusIndicator

---

**SetRowFocusIndicator**

**Description**

Specifies the visual indicator that identifies the current row in the DataWindow control. You can use the standard dotted-line rectangle of Windows, PowerBuilder’s pointing hand, or an image stored in a PowerBuilder Picture control.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>
**SetRowFocusIndicator**

### Syntax

**PowerBuilder**

```powershell
integer dwcontrol.SetRowFocusIndicator ( RowFocusInd focusindicator {, integer xlocation {, integer ylocation } } )
integer dwcontrol.SetRowFocusIndicator ( Picture picturename {, integer xlocation {, integer ylocation } } )
```

**Web ActiveX**

```powershell
number dwcontrol.SetRowFocusIndicator ( number focusindicator , number xlocation , number ylocation )
```

### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control or child DataWindow in which you want to set the row focus indicator.</td>
</tr>
</tbody>
</table>
| `focusindicator` or `picturename` | The visual indicator for the current row. Valid values are:  
   - In PowerBuilder a value of the RowFocusInd enumerated datatype or the name of a PowerBuilder Picture control whose image you want to use.  
   - In the Web ActiveX an integer identifying a RowFocusInd image.  
   For a list of valid enumerated datatype values, see RowFocusInd on page 485. |
| `xlocation` (optional) | The x coordinate in PowerBuilder units of the position of the hand or bitmap relative to the upper-left corner of the row. |
| `ylocation` (optional) | The y coordinate in PowerBuilder units of the position of the hand or bitmap relative to the upper-left corner of the row. |

### Return value

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, SetRowFocusIndicator returns null.

### Usage

Sets the current row indicator in `dwcontrol` to `focusindicator`. If you select Hand or a Picture control as the indicator, PowerBuilder displays the indicator at the left side of the body of the DataWindow unless you specify location coordinates (`xlocation`, `ylocation`). The default location is 0,0 (the left side of the body of the DataWindow control).

### Pictures as row focus indicators

To use a picture as the row focus indicator, set up the Picture control in the Window painter. Place the Picture control in the window that contains the DataWindow control and then reference it in the SetRowFocusIndicator method. You can hide the picture or place it under the DataWindow control so the user does not see the control itself.
Examples

This statement sets the row focus indicator in dw_employee to the pointing hand:

```
   dw_employee.SetRowFocusIndicator(Hand!)
```

If p_arrow is a Picture control in the window, the following statement sets the row focus indicator in dw_employee to p_arrow:

```
   dw_employee.SetRowFocusIndicator(p_arrow)
```

GetRow
SetRow

SetSelfLink

Description

Specifies the URL and page parameters for the current page of the Web DataWindow.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

Web DataWindow server component

```
   string dwcomponent.SetSelfLink( string selflink, string selflinkargs )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to an Web DataWindow server component.</td>
</tr>
<tr>
<td>selflink</td>
<td>The URL for the current page. It cannot include parameters. Parameters may be added when HTML is generated.</td>
</tr>
<tr>
<td>selflinkargs</td>
<td><em>Selflink</em> is used to generate URLs for navigation buttons that obtain additional rows from the result set and for other buttons that reload the page, such as Update and Retrieve.</td>
</tr>
<tr>
<td></td>
<td>Sets the value of the HTMLGen.SelfLink property for the DataWindow object associated with the server component.</td>
</tr>
</tbody>
</table>
SetSelfLink

Argument | Description
--- | ---
selflinkargs | A string in the form:

```
argname=exp1 | argname = 'exp2' } ...
```

Argname is a page parameter to be passed to the server.

*Exp* is a DataWindow string expression that is evaluated, converted using URL encoding, and used as the value of *argname* in generated HTML.

The evaluated *selflinkargs* expressions are included in the generated HTML as hidden fields. The arguments supply information, such as retrieval arguments, that the server needs to render additional pages of the result set.

Return value

Returns an empty string if successful and the syntax error message from the Modify method if it fails.

Usage

This method calls the Modify method of the server component’s DataStore to set the property.

For information about using the Web DataWindow, see the DataWindow Programmers Guide.

**Reason for self-link information** The first time the client browser requests the page template, it can pass page specific information using GET or POST and the page can use those values in the server-side scripts. However, when the page is reloaded because of user interactions with the Web DataWindow, that information will not be passed to the page automatically.

To make the information available, you specify a *selflinkargs* string that becomes page parameters in the reloaded page. Typically, you would use self-link parameters to provide:

- Login information from another page
- DataWindow object name
- Retrieval arguments for the DataWindow object

**Getting the URL for the page** To correctly reload the page in response to user actions, the server component needs to know the URL of the page template. You can get this information from the name property of the document object header or the SCRIPT_NAME server variable.

In a JSP page, you must parse the return value from a request.getRequestURI call:

```java
String URI = request.getRequestURI();
String [] myArray = URI.split ("/");
String pageName = myArray [myArray.length-1];
```
In ASP, use the `ServerVariables` method of the Request object:

```javascript
var pageName = Request.ServerVariables( "SCRIPT_NAME" );
```

Self-link arguments for `SetSelfLink`  
The syntax for specifying self-link arguments is:

```javascript
pageparam='expression'|pageparam='expression'
```

The expression is a DataWindow expression that is evaluated to a string. Usually, you will be passing constant string values that have already been passed to the page as page parameters.

The expression is enclosed in quotes, and if the value is a constant, it must also be enclosed in quotes. For example, if a page parameter has the value `Johnson`, the value of the expression must be enclosed in two sets of quote marks: `"Johnson"`.

To get the value from the current Logname parameter, which is already defined for the page, you build the expression using the Logname page parameter. The single quotes and inner double quotes are embedded in the expression. The current value is inserted between the quotes:

```javascript
String logname = (String) request.getParameter("Logname");
String linkargs = "logname='"" + logname + ""'";
```

If the DataWindow object requires retrieval arguments, they must be provided to the reloaded page in `selfLinkargs`. For an example of using `SetSelfLink` for setting up retrieval arguments as page parameters, see *Retrieve*.

**Examples**

This server-side script specifies hyperlink information for the page. The value of the empid column is stored in the page parameter `EMPID`:

```javascript
webDW.SetSelfLink("mydwpage.html", "EMPID = 'String(empid)'");
```

This hyperlink information refers to the JSP page by name. The page is regenerated by calling the template again. There are no link arguments:

```javascript
webDW.SetSelfLink("salesrpt.jsp", "");
```

This ASP example uses the `ServerVariables` method of the Request object to get the `SCRIPT_NAME` variable:

```javascript
var pageName = Request.ServerVariables( "SCRIPT_NAME" );
webDW.SetSelfLink(pageName, "");
```
**SetServerServiceClasses**

**Description**

Tells the server component to trigger custom events defined in user objects for data validation. These user objects, referred to as service classes, must be defined in the PBL or PBD containing the DataWindow object for the server component.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

**Syntax**

**Web DataWindow server component**

```java
short dwcomponent.SetServerServiceClasses (string servicenames)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component.</td>
</tr>
<tr>
<td>servicenames</td>
<td>A string whose value is a list of PowerBuilder custom class user objects. The user objects must be in the PBL or PBD containing the DataWindow for the server component. Separate user object names with a semicolon.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if a specified service class does not exist.

---

In JSP you must parse the return value from a `request.getRequestURI` call. This example also sets up a page parameter for the reloaded page using the page parameter Logname:

```java
String URI = request.getRequestURI();
String [] myArray = URI.split("/");
String pageName = myArray [myArray.length-1];
String logname = (String)
    request.getParameter("Logname");
String linkargs =
    "Logname='" + logname + "'";
webDW.SetSelfLink( pageName, linkargs);
```
Usage

The main use of service classes is to provide data validation using server-side business logic.

Service classes implement one or more user-defined events with these names and signatures:

- `long dberror ( long sqldbcode, string sqlerrtext, string sqlsyntax, dwbuffer buffer, long row, datastore ds )`
- `long retrievestart ( datastore ds )`
- `long retrieveend ( long rowcount, datastore ds )`
- `long sqlpreview ( sqlpreviewfunction request, sqlpreviewtype sqltype, string sqlsyntax, dwbuffer buffer, long row, datastore ds )`
- `long updatestart ( datastore ds )`
- `long updateend ( long rowsinserted, long rowsupdated, long rowsdeleted, datastore ds )`
- `long htmlcontextapplied ( string action, datastore ds )`

The custom events can use the same return codes as the corresponding standard DataWindow events documented in Chapter 8, “DataWindow Events.” By setting a return code, a custom event can cause the event action to be canceled in the server component.

When the standard DataWindow event occurs in the server component, the component triggers the custom event in each of the listed service classes. One or more of the components can implement the event. A service class only needs to implement the events whose outcome it wants to influence. Any of the service classes can set an event return code that cancels the event action in the server component.

Runtime errors

Instantiated service objects run in the same objects space as the server component. If a runtime error occurs in the service object, it could cause HTML generation to fail.

For information about using the Web DataWindow, see the DataWindow Programmers Guide.

Examples

This JavaScript example for a server-side script specifies a list of service classes that implement events:

```javascript
dwMine.SetServerServiceClasses(
    "uo_update;uo_retrieve;uo_dberror" );
```
SetServerSideState

Description
Tells the server component whether to attempt to maintain its state by saving the retrieved data and leaving the transaction open. Keeping the retrieved data means that the component does not need to reconnect and retrieve data every time a method is called.

When the Web DataWindow is running as an EAServer component, you must call SetServerSideState if you want the component to save state information. In other server environments, you only need to keep a reference to the component in the session object of the page server. The server component will attempt to keep the retrieved data available until ServerSideState is set to false or the server component goes away.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

Syntax

Web DataWindow server component

    string dwcomponent.SetServerSideState ( boolean maintainstate )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcomponent</td>
<td>A reference to a Web DataWindow server component</td>
</tr>
<tr>
<td>maintainstate</td>
<td>Specifies whether the server will attempt to maintain its state between method calls. Values are:</td>
</tr>
</tbody>
</table>

- True – The server component will keep the result set and keep the transaction open if possible.
- False – (Default) The result set is not saved and the server component uses information passed back from the client to retrieve the result set again and remember any uncommitted changes.

Events:
- HTMLContextApplied
- DBError
- RetrieveStart
- RetrieveEnd
- SQLPreview
- UpdateStart
- UpdateEnd
### Return value
Returns an empty string if it succeeds and an error message from EAServer if it fails.

### Usage

**How state is maintained for a stateless component** The Web DataWindow can run in a fully stateless server environment. Variables in the Web page keep information about the rows being viewed and changes the user makes and this information is communicated to the server component as needed so the component can restore its state each time it is called. Restoring its state includes retrieving data from the database each time the page is reloaded, including each time the user navigates to another page.

**Performance impact of a stateless component** Operating in a stateless mode minimizes use of server resources but can decrease performance. The client maintains the state of the server component in string form and the information is sent back and forth with every request. Also, when state is not maintained on the server, the component must connect to the database and retrieve data each time it is called. If the component server does not do connection caching, response time for the client could be very slow.

**Maintaining state on the server** You can increase performance by maintaining state on the server. To maintain state, the page server’s session object keeps a reference to the server component. If the server component is running in EAServer, you must also mark the component as a stateful object. You can do this by calling `SetServerSideState` or by setting the component’s serverSideState property in EAServer Manager.

Maintaining state on the server will provide faster response time if the same component is accessed again. However, it also increases the server resources used for each client connection.

To minimize impact on server resources, a short timeout on a session lets the server get rid of a component that might not be requested again. If the component is called again, its state can be restored from the client state information.

You can also increase performance by calling `Update` frequently.

For information about using the Web DataWindow, see the *DataWindow Programmers Guide*.

### Examples
This example specifies that the EAServer component should maintain state:

```javascript
webDW.SetServerSideState( true );
```

Update
SetSort

Description
Specifies sort criteria for a DataWindow control or DataStore.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer *dwcontrol.SetSort* ( string *format*)

**Web DataWindow client control and Web ActiveX**

number *dwcontrol.SetSort* ( string *format*)

**Web DataWindow server component**

short *dwcontrol.SetSort* ( string *format*)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>dwcontrol</em></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td><em>format</em></td>
<td>A string whose value is valid sort criteria for the DataWindow (see Usage). The expression includes column names or numbers. A column number must be preceded by a pound sign (#). If <em>format</em> is null, PowerBuilder prompts you to enter the sort criteria.</td>
</tr>
</tbody>
</table>

Return value
Returns 1 if it succeeds and –1 if an error occurs.

Usage
A DataWindow object can have sort criteria specified as part of its definition. SetSort overrides the definition, providing new sort criteria for the DataWindow. However, it does not actually sort the rows. Call the Sort method to perform the actual sorting.

The sort criteria for a column have one of the forms shown in the following table, depending on whether you specify the column by name or number.
Table 9-10: Examples for specifying sort order

<table>
<thead>
<tr>
<th>Syntax for sort order</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnname order</td>
<td>&quot;emp_lname A&quot;</td>
</tr>
<tr>
<td></td>
<td>&quot;emp_lname asc, dept_id desc&quot;</td>
</tr>
<tr>
<td># columnnumber order</td>
<td>&quot;#3 A&quot;</td>
</tr>
</tbody>
</table>

The following table shows the recognized values for order. These values are case insensitive. For example, as, s, A, or S all specify a case-sensitive sort in ascending order.

Table 9-11: Recognized values for sort order

<table>
<thead>
<tr>
<th>Order value</th>
<th>Resulting sort order</th>
</tr>
</thead>
<tbody>
<tr>
<td>a, asc, ascending, ai, i</td>
<td>Case-insensitive ascending</td>
</tr>
<tr>
<td>d, desc, descending, di</td>
<td>Case-insensitive descending</td>
</tr>
<tr>
<td>as, s</td>
<td>Case-sensitive ascending</td>
</tr>
<tr>
<td>ds</td>
<td>Case-sensitive descending</td>
</tr>
</tbody>
</table>

If you omit order or specify an unrecognized string, the sort is performed in ascending order and is case insensitive. You can specify secondary sorting by specifying criteria for additional columns in the format string. Separate each column specification with a comma.

To let the user specify the sort criteria for a DataWindow control, you can pass a null string to the SetSort method. PowerBuilder displays the Specify Sort Columns dialog with the sort specifications blank. Then you can call Sort to apply the user’s criteria. You cannot pass a null string to the SetSort method for a DataStore object.

Examples

This statement sets the sort criteria for dw_employee so emp_status is sorted in ascending order and within each employee status, emp_salary is sorted in descending order:

```plaintext
dw_employee.SetSort("emp_status asc, emp_salary desc")
```

If emp_status is column 1 and emp_salary is column 5 in dw_employee, then the following statement is equivalent to the sort specification above:

```plaintext
dw_employee.SetSort("#1 A, #5 D")
```

This example defines sort criteria to sort the status column in ascending order and the salary column in descending order within status. Both sorts are case sensitive. After assigning the sort criteria to the DataWindow control dw_emp, it sorts dw_emp:

```plaintext
string newsort
newsort = "emp_status as, emp_salary ds"
```
The following example sets the sort criteria for dw_main to null, causing
PowerBuilder to display the Specify Sort Columns dialog so that the user can
specify sort criteria. The Sort method applies the criteria the user specifies:

```plaintext
string null_str
SetNull(null_str)
dw_main.SetSort(null_str)
dw_main.Sort()
```

See also
Sort

---

**SetSQLPreview**

**Description**
Specifies the SQL statement for a DataWindow control or DataStore that
PowerBuilder is about to send to the database.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
integer dwcontrol.SetSQLPreview ( string sqlsyntax )
```

**Web ActiveX**

```javascript
number dwcontrol.SetSQLPreview ( string sqlsyntax )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
<tr>
<td>sqlsyntax</td>
<td>A string whose value is valid SQL syntax for the SQL statement that will be submitted to the database</td>
</tr>
</tbody>
</table>

**Return value**
Returns 1 if it succeeds and 0 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**
Use SetSQLPreview to modify syntax before you update the database with changes in the DataWindow object.
To obtain the current SQL statement in the SQLPreview event, look at the sqlsyntax argument.

**When to call SetSQLPreview**
Call this method only in the script for the SQLPreview event.

**Examples**
This statement sets the current SQL string for the DataWindow dw_1:

```
dw_1.SetSQLPreview( &
    "INSERT INTO billings VALUES(100, " + &
    String(Current_balance) + ")")
```

GetSQLPreview
GetUpdateStatus

**SetSQLSelect**

**Description**
Specifies the SQL SELECT statement for a DataWindow control or DataStore.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web Server component</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**
```
integer dwcontrol.SetSQLSelect ( string statement )
```

**Web DataWindow server component**
```
short dwcontrol.SetSQLSelect ( string statement )
```

**Web ActiveX**
```
number dwcontrol.SetSQLSelect ( string statement )
```
SetSQLSelect

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>The name of the DataWindow control, DataStore, or child DataWindow for which you want to change the SELECT statement.</td>
</tr>
<tr>
<td>statement</td>
<td>A string whose value is the SELECT statement for the DataWindow object. The statement must structurally match the current SELECT statement (that is, it must return the same number of columns, the columns must be the same datatype, and the columns must be in the same order).</td>
</tr>
</tbody>
</table>

Return value

SetSQLSelect returns 1 if it succeeds and –1 if the SELECT statement cannot be changed. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Use SetSQLSelect to dynamically change the SQL SELECT statement for a DataWindow object in a script.

If the DataWindow is updatable, PowerBuilder validates the SELECT statement against the database and DataWindow column specifications when you call the SetSQLSelect method. Each column in the SQL SELECT statement must match the column type in the DataWindow object. The statement is validated only if the DataWindow object is updatable.

You must use the SetTrans or SetTransObject method to set the transaction object before the SetSQLSelect method will execute.

If the new SELECT statement has a different table name in the FROM clause and the DataWindow object is updatable, then PowerBuilder must change the update information for the DataWindow object. PowerBuilder assumes the key columns are in the same positions as in the original definition. The following conditions would make the DataWindow not updatable:

- There is more than one table in the FROM clause
- A DataWindow update column is a computed column in the SELECT statement

If changing the SELECT statement makes the DataWindow object not updatable, the DataWindow control cannot execute an Update method call for the DataWindow object in the future.
Limitations to using SetSQLSelect
Use SetSQLSelect only if the data source for the DataWindow object is a SQL SELECT statement without retrieval arguments and you want PowerBuilder to modify the update information for the DataWindow object:

```
dw_1.Modify("DataWindow.Table.Select='select...'")
```

Modify does not verify the SELECT statement or change the update information, so it is faster but more susceptible to user error. Although you can use Modify when arguments are involved, this is not recommended because of the lack of verification.

Examples
If the current SELECT statement for dw_emp retrieves no rows, the following statements replace it with the syntax in NewSyn:

```
string OldSyn, NewSyn
OldSyn = &
    'SELECT employee.EMP_Name FROM employee' &
    + 'WHERE salary < 70000'
NewSyn = 'SELECT employee.EMP_Name FROM employee' &
    + 'WHERE salary < 100000'

IF dw_emp.Retrieve() = 0 THEN
    dw_emp.SetSQLSelect(NewSyn)
    dw_emp.Retrieve()
END IF
```

SetTrans
SetTransObject
Update

SetTabOrder
Description
Changes the tab sequence number of a column in a DataWindow control to the specified value.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>
SetTabOrder

Syntax

**PowerBuilder**

integer `dwcontrol.SetTabOrder ( integer column, integer tabnumber )`
integer `dwcontrol.SetTabOrder ( string column, integer tabnumber )`

**Web ActiveX**

number `dwcontrol.SetTabOrder ( number column, number tabnumber )`
number `dwcontrol.SetTabOrder ( string column, number tabnumber )`

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control or child DataWindow in which you want to define the tab order.</td>
</tr>
<tr>
<td><code>column</code></td>
<td>The column to which you are assigning a tab value. <code>Column</code> can be a column number or a column name. The column number is the number of the column as it is listed in the Column Specification view of the DataWindow painter—not necessarily the number of the column in the Design view.</td>
</tr>
<tr>
<td><code>tabnumber</code></td>
<td>The tab sequence number (0 - 9999) you want to assign to the DataWindow column. 0 removes the column from the tab order, which makes it read-only.</td>
</tr>
</tbody>
</table>

Return value

Returns the previous tab value of the column if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

You can change a column in a DataWindow object to read-only by changing the tab sequence number of the column to 0.

Examples

This statement changes column 4 of `dw_Employee` to read-only:

```
dw_Employee.SetTabOrder(4, 0)
```

These statements change column 4 of `dw_employee` to read-only and later restore the column to its original tab value with read/write status:

```java
integer OldTabNum
// Set OldTabNum to the previous tab order value
OldTabNum = dw_employee.SetTabOrder(4, 0)
... // Some processing
// Return column 4 to its previous tab value.
dw_employee.SetTabOrder(4, OldTabNum)
```
SetText

Description
Replaces the text in the edit control over the current row and column in a DataWindow control or DataStore.

Applies to
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

integer *dwcontrol*.SetText ( string *text*)

**Web ActiveX**

number *dwcontrol*.SetText ( string *text*)

Argument | Description
---|---
*dwcontrol* | The name of the DataWindow control or DataStore in which you want to specify the text in the current row and column.
*text* | A string whose value you want to put in the current row and column. The value must be compatible with the datatype of the column.

Return value
Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage
SetText only sets the value in the edit control. When the user changes focus to another row and column, PowerBuilder accepts the text as the item in the row and column.

**Using SetText in the ItemChanged and ItemError events** In the ItemChanged or ItemError event, PowerBuilder or your own script might determine that the value in the edit control is invalid or that it needs further processing. You can call SetItem to specify a new item value for the row and column.

If you want the user to have an opportunity to enter a different value, after calling SetItem you can call SetText to put that same value in the edit control so that the user sees the value too. You can also call SetText without calling SetItem. In the script, use a return code that rejects the value in the edit control, avoiding further processing, but does not allow the focus to change. To retain focus and display an error message, return 1 for ItemChanged or 0 for ItemError.
When you use a return code that rejects the data the user entered but allows the focus to change (a return code of 2 in the script for the ItemChanged event or 3 in the ItemError event), you do not need to call `SetText` because the value set with `SetItem` displays when the focus changes.

**Examples**

These statements replace the value of the current row and column in `dw_employee` with Tex and then call `AcceptText` to accept and move Tex into the current column. (Do not use this code in the ItemChanged or ItemError event because it calls `AcceptText`.)

```powershell
dw_employee.SetText("Tex")
dw_employee.AcceptText()
```

This example converts a number that the user enters in the column called credit to a negative value and sets both the item and the edit control’s text to the negative number. This code is the script for the ItemChanged event. The data argument holds the newly entered value:

```powershell
integer negative

IF dwo.Name = "credit" THEN
  IF Integer(data) > 0 THEN
    // Convert to negative if it’s positive
    negative = Integer(data) * -1

    // Change the primary buffer value.
    This.SetItem(row, "credit", negative)

    // Change the value in the edit control
    This.SetText(String(negative))
    RETURN 1
  END IF
END IF
```

</tbody>
</table>

**Syntax 1 Using values from an external transaction object**

Sets the values in the internal transaction object for a DataWindow control or DataStore to the values from the specified transaction object. The transaction object supplies connection settings, such as the database name.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

**PowerBuilder**

```powershell
integer dwcontrol.SetTrans ( transaction transaction )
```

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow in which you want to set the values of the internal transaction object</td>
</tr>
<tr>
<td>transaction</td>
<td>The name of the transaction object from which you want dwcontrol to get values</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, the method returns null.

**Usage**

In most cases, use the SetTransObject method to specify the transaction object. It is more efficient and allows you to control when changes get committed to the database.

SetTrans copies the values from a specified transaction object to the internal transaction object for the DataWindow control or DataStore. When you use SetTrans in a script, the DataWindow uses its internal transaction object and automatically connects and disconnects as needed; any errors that occur cause an automatic rollback. With SetTrans, you do not specify SQL statements, such as CONNECT, COMMIT, and DISCONNECT. The DataWindow control connects and disconnects after each Retrieve or Update function.
If you use `SetTrans` for an EAServer component, you must not set the UseContext Object database parameter to `Yes`.

### Use `SetTransObject` with composite DataWindows

You must use `SetTransObject` with DataWindow objects that use the Composite presentation style. Composite DataWindows are containers for other DataWindow objects and do not have any internal transaction information of their own.

If you use `SetTrans` with each nested DataWindow in a composite DataWindow, disconnect does not occur until the PowerBuilder session ends.

Use `SetTrans` when you want PowerBuilder to manage the database connections automatically because you have a limited number of available connections or expect to use the application from a remote location. `SetTrans` is appropriate when you are only retrieving data and do not need to hold database locks on records the user is modifying. For better performance, however, you should use `SetTransObject`.

### DBMS connection settings

You must set the parameters required to connect to your DBMS in the transaction object before you can use the transaction object to set the DataWindow's internal transaction object and connect to the database.

### Updating more than one table

When you use `SetTrans` to specify the transaction object, you cannot update multiple DataWindow objects or multiple tables within one object.

### Examples

This statement sets the values in the internal transaction object for `dw_employee` to the values in the default transaction object SQLCA:

```pascal
dw_employee.SetTrans(SQLCA)
```

The following statements change the database type and password of `dw_employee`. The first two statements create the transaction object `emp_TransObj`. The next statement uses the `GetTrans` method to store the values of the internal transaction object for `dw_employee` in `emp_TransObj`. The next two statements change the database type and password. The `SetTrans` method assigns the revised values to `dw_employee`:

```pascal
// Name the transaction object.
transaction emp_TransObj

// Create the transaction object.
emp_TransObj = CREATE transaction
```
CHAPTER 9 Methods for the DataWindow Control

// Fill the new object with the original values.
dw_employee.GetTrans(emp_TransObj)
// Change the database type.
emp_TransObj.DBMS = "Sybase"
// Change the password.
emp_TransObj.LogPass = "cam2"

// Put the revised values into the
// DataWindow transaction object.
dw_employee.SetTrans(emp_TransObj)

GetTrans
SetTransObject

Syntax 2 For the Web DataWindow server component

Description
Specifies connection information for the Web DataWindow, such as the database name.

Applies to
Syntax
Web DataWindow server component

integer dwcontrol.SetTrans ( string dbms, string dbparm, string lock,
string logid, string logpass, string database, string servername )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow in which you want to set the values of the internal transaction object.</td>
</tr>
<tr>
<td>dbms</td>
<td>PowerBuilder vendor identifier.</td>
</tr>
</tbody>
</table>
| dbparm      | DBMS-specific parameters. For example, this connection string uses the Sybase JConnect driver and connects to SQL Anywhere running on the local machine (localhost):
| lock        | The isolation level. For information about values for different types of connections, see Connecting to Your Database. |
| logid       | The name or ID to be used to log on to the database server. |
| logpass     | The password to be used to log on to the server. |
**SetTrans**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>The name of the database to which you are connecting.</td>
</tr>
<tr>
<td>servername</td>
<td>The name of the server where the database resides.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

**Usage**

When the server component is installed in EAServer, you must use EAServer Manager to set up a connection cache for the component.

You use SetTrans when you want the DataWindow engine to manage database connections, transaction state primitives, and related EAServer component deactivation. This is incompatible with the UseContextObject database parameter, which you set only to retain control of connection and transaction functions yourself.

Because the default Web DataWindow component uses SetTrans to specify database connection information, you must not set the UseContextObject database parameter to Yes in your database profile or in the EAServer properties for the component.

**Examples**

This statement specifies ODBC connection information for the server component called webDW:

```powershell
webDW.SetTrans("ODBC", "ConnectString='DSN=EAS Demo DB V10; UID=dba;PWD=sql'", ", ", ", ", ", ");
```

This statement specifies JDBC connection information:

```powershell
```

**See also**

Retrieve
# SetTransObject

**Description**

Causes a DataWindow control or DataStore to use a programmer-specified transaction object. The transaction object provides the information necessary for communicating with the database.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
integer dwcontrol.SetTransObject ( transaction transaction )
```

**Web ActiveX**

```
number dwcontrol.SetTransObject ( transaction transaction )
```

**Argument | Description**
---|---
`dwcontrol` | A reference to a DataWindow control, DataStore, or child DataWindow in which you want to use a programmer-specified transaction object rather than the DataWindow control’s internal transaction object
`transaction` | The name of the transaction object you want to use in the `dwcontrol`

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

**Usage**

**Transaction objects in PowerBuilder**  
A programmer-specified transaction object gives you more control over the database transactions and provides efficient application performance. You control the database connection by using SQL statements such as CONNECT, COMMIT, and ROLLBACK.

Since the DataWindow control does not have to connect to the database for every RETRIEVE and UPDATE statement, these statements run faster. You are responsible for committing and rolling back transactions after you call the Update method, using code like the following:

```
IF dw_Employee.Update()>0 THEN
    COMMIT USING emp_transobject;
ELSE
    ROLLBACK USING emp_transobject;
END IF
```
You must set the parameters required to connect to your DBMS in the transaction object before you can use the transaction object to connect to the database. PowerBuilder provides a global transaction object called SQLCA, which is all you need if you are connecting to one database. You can also create additional transaction objects, as shown in the examples.

To use `SetTransObject`, write code that does the following tasks:

1. Set up the transaction object by assigning values to its fields (usually in the application’s Open event).
2. Connect to the database using the SQL `CONNECT` statement and the transaction object (in the Open event for the application or window).
3. Call `SetTransObject` to associate the transaction object with the DataWindow control or DataStore (usually in the window’s Open event).
4. Check the return value from the `Update` method and follow it with a SQL `COMMIT` or `ROLLBACK` statement, as appropriate.

If you change the DataWindow object associated with the DataWindow control (or DataStore) or if you disconnect and reconnect to a database, the connection between the DataWindow control (or DataStore) and the transaction object is severed. You must call `SetTransObject` again to reestablish the connect.

**SetTransObject versus SetTrans**
In most cases, use the `SetTransObject` method to specify the transaction object because it is efficient and gives you control over when transactions are committed.

The `SetTrans` method provides another way of managing the database connection. `SetTrans`, which sets transaction information in the internal transaction object for the DataWindow control or DataStore, manages the connection automatically. You do not explicitly connect to the database; the DataWindow connects and disconnects for each database transaction, which is less efficient but necessary in some situations.

For more information, see `SetTrans`.

**Examples**
This statement causes `dw_employee` to use the default transaction object SQLCA:

```powershell
dw_employee.SetTransObject(SQLCA)
```
This statement causes dw_employee to use the programmer-defined transaction object emp_TransObj. In this example, emp_TransObj is an instance variable, but your script must allocate memory for it with the CREATE statement before you use it:

```powerbuilder
emp_TransObj = CREATE transaction
... // Assign values to the transaction object
dw_employee.SetTransObject(emp_TransObj)
```

This example has two parts. The first script, for the application’s Open event, reads database parameters from an initialization file called `MYAPP.INI` and stores the values in the default transaction object (SQLCA). The Database section of `MYAPP.INI` has the same keywords as PowerBuilder’s own `PB.INI` file. The parameters shown are for a SQL Server or Oracle database. The second script, for the window’s Open event, establishes a connection and retrieves data from the database.

The application’s Open event script populates SQLCA:

```powerbuilder
SQLCA.DBMS = ProfileString("myapp.ini", &
    "database", "DBMS", " ")
SQLCA.Database = ProfileString("myapp.ini", &
    "database", "Database", " ")
SQLCA.LogId = ProfileString("myapp.ini", &
    "database", "LogId", " ")
SQLCA.LogPass = ProfileString("myapp.ini", &
    "database", "LogPassword", " ")
SQLCA.ServerName = ProfileString("myapp.ini", &
    "database", "ServerName", " ")
SQLCA.UserId = ProfileString("myapp.ini", &
    "database", "UserId", " ")
SQLCA.DBPass = ProfileString("myapp.ini", &
    "database", "DatabasePassword", " ")
SQLCA.lock = ProfileString("myapp.ini", &
    "database", "lock", " ")
```

The Open event script for the window that contains the DataWindow control connects to the database, assigns the transaction object to the DataWindow, and retrieves data:

```powerbuilder
long RowsRetrieved
string LastName

// Connect to the database.
CONNECT USING SQLCA;
```
// Test whether the connect succeeded.
IF SQLCA.SQLCode <> 0 THEN
    MessageBox("Connect Failed", &
               "Cannot connect to database " &
               + SQLCA.SQLErrText)
    RETURN
END IF

// Set the transaction object to SQLCA.
dw_employee.SetTransObject(SQLCA)

// Retrieve the rows.
LastName = ...
RowsRetrieved = dw_employee.Retrieve(LastName)
// Test whether the retrieve succeeded.
IF RowsRetrieved < 0 THEN
    MessageBox("Retrieve Failed", &
               "Cannot retrieve data from the database.")
END IF

SetTrans

SetValidate

Description
Sets the input validation rule for a column in a DataWindow control or DataStore.

SetValidateByColNum
A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>
CHAPTER 9    Methods for the DataWindow Control

Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.SetValidate ( string column, string rule )
integer dwcontrol.SetValidate ( integer column, string rule )
```

**Web DataWindow server component**

```powerbuilder
short dwcontrol.SetValidate ( string column, string rule )
short dwcontrol.SetValidateByColNum ( short column, string rule )
```

**Web ActiveX**

```powerbuilder
number dwcontrol.SetValidate ( string column, string rule)
number dwcontrol.SetValidate ( number column, string rule)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
</tbody>
</table>
| column       | The column for which you want to set the input validation rule.  
|              | Column can be a column number or a column name.                          |
| rule         | A string whose value is the validation rule for validating the data.          |

Return value

Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Usage

Validation rules are boolean expressions that usually compare the value in the column’s edit control to some other value. When data the user enters fails to meet the criteria established in the validation rule, an ItemError event occurs.

You can specify validation rules in the Database painter or the DataWindow painter, and you can change the rules in scripts using `SetValidate`. A validation rule can include any DataWindow painter function. For more information, see the *Users Guide*.

If you want to change a column’s validation rule temporarily, you can use `GetValidate` to get and save the current rule. To include the value the user entered in the validation rule, use the `GetText` method. You can compare its return value to the validation criteria.

If the validation rule contains numbers, the DataWindow expects the numbers in U.S. format. In PowerBuilder, be aware that the `String` function formats numbers using the current system settings. If you use it to build the rule, specify a display format that produces U.S. notation.

Examples

The following assigns a validation rule to the current column in `dw_employee`. The rule ensures that the data entered is greater than zero:

```powerbuilder
dw_employee.SetValidate(dw_employee.GetColumn(), &
    *Number(GetText ( )) > 0")
```
The following assigns a validation rule to the current column in `dw_employee`. The rule checks that the value entered is less than the value in the Full_Price column:

```plaintext
dw_employee.SetValidate(dw_employee.GetColumn(), &
   "Number(GetText( )) < Full_Price")
```

This example defines a new validation rule for the column `emp_state` in the DataWindow control `dw_employee`. The new rule is `[A-Z]+`, meaning the data in `emp_state` must be all uppercase characters. The text pattern must be enclosed in quotes within the quoted validation rule. The embedded quotes are specified with `~`. The script saves the old rule, assigns the new rule, performs some processing, and then sets the validation rule back to the old rule:

```plaintext
string OldRule, NewRule

NewRule = "Match(GetText(), ~"[A-Z]+~")"

OldRule = dw_employee.GetValidate("emp_state")

dw_employee.SetValidate("emp_state", NewRule)
... //Process data using the new rule.

// Set the validation rule back to the old rule.
dw_employee.SetValidate("emp_state", OldRule)
```

See also

GetValidate

---

**SetValue**

Sets the value of an item in a value list or code table for a column in a DataWindow control or DataStore. (A value list is called a code table when it has both display and data values.) `SetValue` does not affect the data stored in the column.

**SetValueByColNum**

A separate method name is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.
CHAPTER 9  Methods for the DataWindow Control

Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```
integer dwcontrol.SetValue ( string column, integer index, string value )
integer dwcontrol.SetValue ( integer column, integer index, string value )
```

**Web DataWindow server component**

```
short dwcontrol.SetValue ( string column, short index, string value )
short dwcontrol.SetValueByColNum ( short column, short index, string value )
```

**Web ActiveX**

```
number dwcontrol.SetValue ( string column, number index, string value )
number dwcontrol.SetValue ( number column, number index, string value )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control or DataStore.</td>
</tr>
<tr>
<td><code>column</code></td>
<td>The column that contains the value list or code table. <em>Column</em> can be a column number or a column name.</td>
</tr>
<tr>
<td></td>
<td>The edit style of the column can be DropDownListBox, Edit, or RadioButton. <code>SetValue</code> has no effect when <code>column</code> has the EditMask or DropDownListDataWindow edit style.</td>
</tr>
<tr>
<td><code>index</code></td>
<td>The number of the item in the value list or code table for which you want to set the value.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>A string whose value is the new value for the item. For a code table, use a tab (<del>t in PowerBuilder) to separate the display value from the data value (&quot;Texas</del>tTX&quot;). The data value must be a string that can be converted to the datatype of the column.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, in PowerBuilder and JavaScript the method returns null.

Examples

This statement sets the value of item 3 in the value list for the column `emp_state` of `dw_employee` to Texas:

```
dw_employee.SetValue("emp_state", 3, "Texas")
```
This statement sets the display value of item 3 in the code table for the column named emp_state of dw_employee to Texas and the data value to TX:

```
dw_employee.SetValue("emp_state", 3, "Texas~tTX")
```

The following statements use a SQL cursor and FETCH statement to populate the ListBox portion of a DropDownListBox style column called product_col of a DataWindow object with code table values:

```powershell
integer prod_code, i = 1
string prod_name

DECLARE prodcur CURSOR FOR
    SELECT product.name, product.code
    FROM product USING SQLCA;

CONNECT USING SQLCA;
IF SQLCA.SQLCode <> 0 THEN
    MessageBox("Status","Connect Failed " & + SQLCA.SQLErrText)
    RETURN
END IF

OPEN prodcur;
IF SQLCA.SQLCode <> 0 THEN
    MessageBox("Status","Cursor Open Failed " & + SQLCA.SQLErrText)
    RETURN
END IF

FETCH prodcur INTO :prod_name, :prod_code;

DO WHILE SQLCA.SQLCode = 0
    dw_products.SetValue("product_col", i, & prod_name + "-t" + String(prod_code))
    i = i + 1
    FETCH prodcur INTO :prod_name, :prod_code;
LOOP

CLOSE prodcur;
DISCONNECT USING SQLCA;
```

GetValue
**SetWeight**

**Description**
Specifies the types of JavaScript code that will be included in the generated HTML or XHTML.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Web</td>
<td>Server component</td>
</tr>
</tbody>
</table>

**Syntax**

def DWServerComponent.SetWeight( allowupdate, validation, events, clientscriptable, clientformatting )

**Argument** | **Description**
--- | ---
dwcomponent | A reference to a Web DataWindow server component.
allowupdate | Specifies whether the generated HTML will be a form with INPUT elements so that the user can change the data. Values are:
- True – The generated HTML is a form. The user can change the data.
- False – The generated HTML is a table. The user cannot change the data.
When allowupdate is false, validation and clientformatting are ignored and no validation or formatting scripts are generated.
validation | Specifies whether the generated HTML will include scripts for validating data the user enters. The scripts implement validation rules defined in the DataWindow object. Values are:
- True – The generated HTML has scripts that implement validation rules.
- False – The generated HTML does not validate user-entered data.
Sets the value of the HTMLGen.ClientValidation property for the DataWindow object associated with the server component.
events | Specifies whether the generated HTML will include code for triggering events. Values are:
- True – The generated HTML has scripts that trigger events.
- False – The generated HTML does not trigger events.
Sets the value of the HTMLGen.ClientEvents property for the DataWindow object associated with the server component.
The available events are listed in the “DataWindow event cross-reference” on page 502.
SetWeight

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientscriptable</td>
<td>Specifies whether the generated HTML allows client-side scripts to call methods of the client control. Values are:</td>
</tr>
<tr>
<td></td>
<td>- True – The generated HTML includes methods that the client scripts can call.</td>
</tr>
<tr>
<td></td>
<td>- False – The generated HTML does not include methods.</td>
</tr>
<tr>
<td></td>
<td>This option adds approximately 100K to the generated HTML.</td>
</tr>
<tr>
<td></td>
<td>Sets the value of the HTMLGen.ClientScriptable property for the DataWindow object associated with the server component.</td>
</tr>
</tbody>
</table>

| clientformatting | Specifies whether the generated HTML will include scripts for formatting data the user enters. The scripts implement display formats defined in the DataWindow object. Values are: |
|                 | - True – The generated HTML has scripts that format user-entered data.                                                                        |
|                 | - False – The generated HTML does not format user-entered data.                                                                               |
|                 | Sets the value of the HTMLGen.ClientFormatting property for the DataWindow object associated with the server component.                         |

Return value

Returns an empty string if successful and the syntax error message from the Modify method if it fails.

Usage

When code for more features is included, the Web DataWindow becomes a more robust tool for data entry and manipulation, allowing data validation, formatting, and client-side scripts that react to user actions. However, if your application does not use some of these features, you can decrease the size of the generated code by setting the appropriate options to false.

This method calls the Modify method of the server component’s DataStore to set the properties.

These properties can also be set in the DataWindow painter so that the settings are part of the DataWindow object definition.

For information about using the Web DataWindow, see the DataWindow Programmers Guide.

Examples

This example specifies updating of data is not supported in the server component webDW, but events are supported so client-side scripts can respond to user actions:

```powerbuilder
webDW.SetWeight( false, false, true, true, false );
```
This example specifies that all features are supported except client-side scripting. Scripts in the Web page will not be able to call Web DataWindow client methods:

```powershell
webDW.SetWeight( true, true, true, false, true );
```

This example specifies that all features are supported:

```powershell
webDW.SetWeight( true, true, true, true, true );
```

Modify
SetAction
HTMLGen.property

SetWSObject

Description
Causes a DataWindow control or DataStore to use a programmer-specified Web service connection object. The connection object provides the information necessary for communicating with a Web service data source.

Applies to
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

Syntax

**PowerBuilder**

```powershell
integer dwcontrol.SetWSObject( wsconection wsobject )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow in which you want to use a programmer-specified Web service connection object</td>
</tr>
<tr>
<td><code>wsobject</code></td>
<td>The name of the connection object you want to use in the <code>dwcontrol</code></td>
</tr>
</tbody>
</table>

Return value
Returns 1 if it succeeds and -1 if an error occurs. If the WSConnection object is null, in PowerBuilder the method returns null.

Usage
You call the `SetWSObject` method to pass an instance of the WSConnection object and connect to a Web service data source when the Web service requires user-related, session-related, or authentication information. If the Web service does not require this information, you do not need to use the WSConnection object (or call `SetWSObject`) to access Web service data.
The following code instantiates a WSConnection object, then sets the object as the connection object for a Web service data source:

```plaintext
int ii_return
wsconnection ws_1
ws_1 = create wsconnection
ws_1.username = "johndoe"
ws_1.password = "mypassword"
ws_1.endpoint = "myendpoint"
ws_1.authenticationmode = "basic"
ws_1.usewindowsintegratedauthentication = true
ii_return = dw_1.setwsobject (ws_1)
```

See also SetTransObject
**ShareData**

**Description**
Shares data retrieved by one DataWindow control (or DataStore), which is referred to as the primary DataWindow, with another DataWindow control (or DataStore), referred to as the secondary DataWindow.

The controls do not share formatting; only the data is shared, including data in the primary buffer, the delete buffer, the filter buffer, and the sort order.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

- **PowerBuilder**
  ```
  integer dwprimary.ShareData ( datawindow dwsecondary )
  integer dwprimary.ShareData ( datastore dwsecondary )
  integer dwprimary.ShareData ( datawindowchild dwsecondary )
  ```

- **Web ActiveX**
  ```
  number dwprimary.ShareData ( datawindow dwsecondary )
  number dwprimary.ShareData ( datawindowchild dwsecondary )
  ```

**Argument | Description**

- **dwprimary**
  The name of the primary DataWindow. The primary DataWindow is the owner of the data. When you destroy this DataWindow, the data disappears. **Dwprimary** can be a child DataWindow but it cannot be a report in a composite DataWindow object or a Crosstab DataWindow object.

- **dwsecondary**
  The name of the secondary DataWindow with which the control **dwprimary** will share the data. The secondary DataWindow can be a child DataWindow or a report in a composite DataWindow object but it cannot be a Crosstab DataWindow object.

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

**Usage**

The columns must be the same for the DataWindow objects in the primary and secondary DataWindow controls, but the SELECT statements may be different. For example, you could share data between DataWindow objects with these SELECT statements:

- `SELECT dept_id from dept`
- `SELECT dept_id from dept where dept_id = 200`
- `SELECT dept_id from employee`
WHERE clause in secondary has no effect
The WHERE clause in the DataWindow object in the secondary DataWindow control has no effect on the number of rows returned. The number of rows returned to both DataWindow controls is determined by the WHERE clause in the primary DataWindow object.

You could also share data with a DataWindow object that has an external data source and columns defined to be like the columns in the primary. To share data between a primary DataWindow and more than one secondary DataWindow control, call ShareData for each secondary DataWindow control.

ShareData shares only the primary buffer of the primary DataWindow with the primary buffer of the secondary DataWindow. A DropDownDataWindow in the secondary DataWindow will not display any data unless you explicitly populate it. You can do this by getting a handle to the DropDownDataWindow (by calling the GetChild method) and either retrieving the DropDownDataWindow or using ShareData to share data from an appropriate data source with the DropDownDataWindow.

To turn off sharing in a primary or secondary DataWindow, call the ShareDataOff method. When sharing is turned off for the primary DataWindow, the secondary DataWindows are disconnected and the data disappears. However, turning off sharing for a secondary DataWindow does not affect the data in the primary DataWindow or other secondary DataWindows.

When you call methods in either the primary or secondary DataWindow that change the data, PowerBuilder applies them to the primary DataWindow control and all secondary DataWindow controls are affected.

For example, when you call any of the following methods for a secondary DataWindow control, PowerBuilder applies it to the primary DataWindow. Therefore, all messages normally associated with the method go to the primary DataWindow control. Such methods include:

- DeleteRow
- Filter
- GetSQLSelect
- ImportFile
- ImportString
- ImportClipboard
- InsertRow
- ReselectRow
- Reset
- Retrieve
There are some restrictions on the use of ShareData:

- **Computed fields in secondary DataWindow controls**
  
  A secondary DataWindow control can have only data that is in the primary DataWindow control. If you add a computed field to a secondary control, it will not display when you run the application unless you also add it to the primary control.

- **Query mode and secondary DataWindows**
  
  When you are sharing data, you cannot turn on query mode for a secondary DataWindow. Trying to set the QueryMode or QuerySort DataWindow object properties results in an error.

- **Crosstab DataWindows**
  
  You cannot use ShareData with a Crosstab DataWindow as the primary or secondary DataWindow.

- **Composite and child DataWindows**
  
  You can use a report in a Composite DataWindow as the secondary DataWindow, but not the primary DataWindow. You can use ShareData with a child DataWindow as the primary or secondary DataWindow.

- **Distributed applications**
  
  You cannot share data between a DataWindow control in a client application and a DataStore in a server application.

### Use DataSource with RichTextEdit controls

To share data between a DataStore or DataWindow and a RichTextEdit control, use the DataSource method.

### Examples

In this example, the programmer wants to allow the user to view two portions of the same data retrieved from the database and uses the ShareData method to accomplish this in the script for the Open event for the window.
The SELECT statement for both DataWindow objects is the same, but the DataWindow object in dw_dept displays only two of the five columns displayed in dw_employee:

```
CONNECT USING SQLCA;
dw_employee.SetTransObject(SQLCA)
dw_employee.Retrieve()
dw_employee.ShareData(dw_dept)
```

These statements share data between two DataWindow controls in different sheets within an MDI frame window:

```
CONNECT USING SQLCA;
mdi_sheet_1.dw_dept.SetTransObject(SQLCA)
mdi_sheet_1.dw_dept.Retrieve()
mdi_sheet_1.dw_dept.ShareData(mdi_sheet_2.dw_dept)
```

This example shares data in a tabular DataWindow with a report in a Composite DataWindow. The name of the report in the Composite DataWindow is dw_1:

```
DataWindowChild dwreport

// Get a reference to the nested report
dw_composite.GetChild("dw_1", dwreport)
dw_tabular.ShareData(dwreport)
```

**See also**

ShareDataOff

---

**ShareDataOff**

**Description**

Turns off the sharing of data buffers for a DataWindow control or DataStore.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object,</td>
</tr>
<tr>
<td></td>
<td>DataStore object</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

- **PowerBuilder**
  
  `integer dwcontrol.ShareDataOff ()`

- **Web ActiveX**
  
  `number dwcontrol.ShareDataOff ()`
CHAPTER 9  Methods for the DataWindow Control

DataWindow Reference

Return value

Returns 1 if it succeeds and –1 if an error occurs. If dwcontrol is null, ShareDataOff returns null.

Usage

Two or more DataWindow controls (or DataStores) can share data. See ShareData for more information about shared data buffers and primary and secondary DataWindows.

When you call ShareDataOff for a secondary DataWindow, that control no longer contains data, but the primary DataWindow and other secondary controls are not affected. When you call ShareDataOff for the primary DataWindow, all secondary DataWindows are disconnected and no longer contain data.

Examples

These statements establish the sharing of data among three DataWindow controls and then turn off sharing for one of the secondary DataWindow controls:

CONNECT USING SQLCA;
dw_corp.SetTransObject(SQLCA)
dw_corp.Retrieve()
dw_corp.ShareData(dw_emp)
dw_corp.ShareData(dw_dept)
...  // Some processing
dw_emp.ShareDataOff()

See also

ShareData

Show

Description

Makes an object or control visible, if it is hidden. If the object is already visible, Show brings it to the top.

Applies to

DataWindow type | Method applies to
---|---
PowerBuilder | DataWindow control

Syntax

PowerBuilder

integer objectname.Show ()

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectname</td>
<td>The name of the object or control you want to make visible (show)</td>
</tr>
</tbody>
</table>
**ShowHeadFoot**

**Return value**

Returns 1 if it succeeds and –1 if an error occurs. If *objectname* is null, Show returns null.

**Usage**

**PowerBuilder environment**

Inherited from GraphicObject. For more details on use with PowerBuilder objects, see Show in the *PowerScript Reference*.

**See also**

Hide

---

**ShowHeadFoot**

**Description**

Displays the panels for editing the header and footer in a RichTextEdit control or hides the panels and returns to editing the main text.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control with RichTextEdit presentation style</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

integer *rtname*.ShowHeadFoot ( boolean *editheadfoot*, {headerfooter} )

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>rtname</em></td>
<td>A reference to the DataWindow control for which you want to edit header and footer information. The DataWindow must have a RichTextEdit presentation style.</td>
</tr>
</tbody>
</table>
| *editheadfoot* | A boolean value specifying the editing panel to display. Values are:  
  - **True** – Display the header and footer editing panels.  
  - **False** – Display the detail editing panel for the document body. |
| headerfooter (optional) | A boolean value specifying whether the insertion point (caret) for editing the header/footer panel is in the header or the footer section. Values are:  
  - **True** Caret is in the header section.  
  - **False** Caret is in the footer section. |

**Return value**

Returns 1 if it succeeds and –1 if an error occurs.

**Usage**

ShowHeadFoot takes effect when the control is in preview mode or when it is in edit mode for the main text. If the control is in preview mode, calling ShowHeadFoot returns to edit mode. The value of *editheadfoot* determines whether the main text or the header and footer panels display.
The `headerfooter` argument is ignored if the `editheadfoot` argument is false. The `headerfooter` argument defaults to “true” if a value is not provided. The header and footer can include input fields for page numbers and dates.

**PowerBuilder RichTextEdit control**
You can use the same syntax with any RichTextEdit control. See `ShowHeadFoot` in the *PowerScript Reference*.

**See also**
Preview for RichTextEdit controls in the *PowerScript Reference*

---

## Sort

**Description**
Sorts the rows in a DataWindow control or DataStore using the DataWindow’s current sort criteria.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```powerbuilder
integer dwcontrol.Sort()
```

**Web DataWindow client control and Web ActiveX**

```powerbuilder
number dwcontrol.Sort()
```

**Web DataWindow server component**

```powerbuilder
short dwcontrol.Sort()
```

**Argument | Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow</td>
</tr>
</tbody>
</table>

**Return value**
Returns 1 if it succeeds and –1 if an error occurs. If `dwcontrol` is null, Sort returns null.
Usage

Sort uses the current sort criteria for the DataWindow. To change the sort criteria, use the SetSort method. The SetSort method is equivalent to using the Sort command on the Rows menu of the DataWindow painter. If you do not call SetSort to set the sort criteria before you call Sort, Sort uses the sort criteria specified in the DataWindow object definition.

When the Retrieve method retrieves data for the DataWindow, PowerBuilder applies the sort criteria that were defined for the DataWindow object, if any. You need to call Sort only after you change the sort criteria with SetSort or if the data has changed because of processing or user input.

For information on letting the user specify sort criteria using the built-in dialog box, see SetSort.

When you sort a DataWindow on a specified column, rows with null data remain at the top, regardless of whether you choose ascending or descending order for your sort criteria. The sort order is performed on a result set returned from a database, but is not necessarily the same sort order used by the database (to return the result set) when an ORDER BY clause is used in a SQL query.

The Sort method uses a typical lexical sort, with symbols, such as a hyphen or underline, ranked higher than alphanumeric characters. It compares characters in the same manner as does a dictionary.

When the Retrieve As Needed option is set, the Sort method cancels its effect. Sort causes all rows to be retrieved so that they are sorted correctly. It also changes the current row to 1 without causing the RowFocusChanged or RowFocusChanging events to fire. These events should be triggered programmatically after the Sort method is called.

Sort has no effect on the DataWindows in a composite report.

Sorting and groups
To sort a DataWindow object with groups or TreeView levels, call GroupCalc after you call Sort.

Web DataWindow client control
Calling Sort causes the page to be reloaded.

If the DataWindow object has retrieval arguments, they must be specified in the HTMLGen.SelfLinkArgs property. For more information, see the HTMLGen.property, the Retrieve method, and the DataWindow Programmers Guide.
All methods that reload the page perform an AcceptText before sending data back to the server. If the method fails (returns -1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.

**PowerBuilder environment**
For use with PowerBuilder ListView and TreeView controls, see Sort in the PowerScript Reference.

### Examples
This example sets dw_employee to be sorted by column 1 ascending and then by column 2 descending. Then it sorts the rows:

```powershell
dw_employee.SetRedraw(false)
dw_employee.SetSort("#1 A, #2 D")
dw_employee.Sort()
dw_employee.SetRedraw(true)
```

In this example, the rows in the DataWindow dw_depts are grouped based on department and the rows are sorted based on employee name. If the user has changed the department of several employees, then the following commands apply the sort criteria so that each group is in alphabetical order and then regroup the rows:

```powershell
dw_depts.SetRedraw(false)
dw_depts.Sort()
dw_depts.GroupCalc()
dw_depts.SetRedraw(true)
```

### See also
GroupCalc
SetSort

---

### TextLine

**Description**
Obtains the text of the line that contains the insertion point. TextLine works for controls that can contain multiple lines.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

```powershell
string editname.TextLine ()
```
**TriggerEvent**

**Web ActiveX**

```
string editname.TextLine()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>editname</code></td>
<td>A reference to a DataWindow control</td>
</tr>
</tbody>
</table>

**Return value**

Returns the text on the line with the insertion point in `editname`. If an error occurs, `TextLine` returns the empty string (""). If `editname` is null, `TextLine` returns null.

**Usage**

`TextLine` reports information about the edit control over the current row and column.

**PowerBuilder environment**

For use with other PowerBuilder controls, see `TextLine` in the *PowerScript Reference*.

**Examples**

In the DataWindow control `dw_letter`, if the insertion point is on line 4 in the edit control and the text on the line is North Carolina, then this example sets `linetext` to North Carolina:

```
string linetext
linetext = dw_letter.TextLine()
```

**See also**

`SelectTextLine`

---

**TriggerEvent**

**Description**

Triggers an event associated with the specified object, which executes the script for that event immediately.

**Applies to**

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

**Syntax**

**PowerBuilder**

```
integer objectname.TriggerEvent ( trigevent event {, long word, long long} )
integer objectname.TriggerEvent ( trigevent event {, long word, string long} )
```

912 PowerBuilder
CHAPTER 9  Methods for the DataWindow Control

### TypeOf

**Description**
Determines the type of an object or control, reported as a value of the Object enumerated datatype.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
</tbody>
</table>

**Syntax**
```
PowerBuilder
   object objectname.TypeOf ()
```

**Argument**
<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name of the object or control for which you want the type</td>
</tr>
</tbody>
</table>
Undo

Return value
Object enumerated datatype. Returns the type of `objectname`. If `objectname` is null, `TypeOf` returns null.

Usage
Inherited from PowerObject. For information, see `TypeOf` in the `PowerScript Reference`.

See also
ClassName

---

**Undo**

**Description**
Cancels the last edit in an edit control, restoring the text to the content before the last change.

**Applies to**
<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control</td>
</tr>
</tbody>
</table>

**Syntax**

- **PowerBuilder**
  
  `integer editname.Undo ( )`

- **Web ActiveX**
  
  `number editname.Undo ( )`

**Argument**

<table>
<thead>
<tr>
<th><code>editname</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>A reference to a DataWindow control. Reverses the last edit in the edit control over the current row and column.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 when it succeeds and –1 if an error occurs. If `editname` is null, `Undo` returns null.

**Usage**
To determine whether the last action can be canceled, call the CanUndo method.

**PowerBuilder environment**

For examples and for use with other PowerBuilder controls, see `Undo` in the `PowerScript Reference`.

**See also**

CanUndo
### Update

**Description**

Updates the database with the changes made in a DataWindow control or DataStore. Update can also call AcceptText for the current row and column before it updates the database.

**UpdateEx**

A separate method name, UpdateEx, is provided as an alternative syntax for the Web DataWindow server component, which cannot use overloaded methods.

### Applies to

<table>
<thead>
<tr>
<th>DataWindow type</th>
<th>Method applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerBuilder</td>
<td>DataWindow control, DataWindowChild object, DataStore object</td>
</tr>
<tr>
<td>Web</td>
<td>Client control, server component</td>
</tr>
<tr>
<td>Web ActiveX</td>
<td>DataWindow control, DataWindowChild object</td>
</tr>
</tbody>
</table>

### Syntax

**PowerBuilder**

```powershell
integer dwcontrol.Update ( { boolean accept, boolean resetflag } )
```

**Web DataWindow client control**

```powershell
number dwcontrol.Update ( )
```

**Web DataWindow server component**

```powershell
short dwcontrol.Update ( )
short dwcontrol.UpdateEx ( boolean accept, boolean resetflag )
```

**Web ActiveX**

```powershell
number dwcontrol.Update ( { boolean accept, boolean resetflag } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control, DataStore, or child DataWindow.</td>
</tr>
<tr>
<td>accept (optional)</td>
<td>A boolean value specifying whether the DataWindow control or DataStore should automatically perform an AcceptText prior to performing the update:</td>
</tr>
<tr>
<td></td>
<td>• True – (Default) Perform AcceptText. The update is canceled if the data fails validation.</td>
</tr>
<tr>
<td></td>
<td>• False – Do not perform AcceptText.</td>
</tr>
<tr>
<td>resetflag (optional)</td>
<td>A boolean value specifying whether dwcontrol should automatically reset the update flags:</td>
</tr>
<tr>
<td></td>
<td>• True – (Default) Reset the flags.</td>
</tr>
<tr>
<td></td>
<td>• False – Do not reset the flags.</td>
</tr>
</tbody>
</table>
**Update**

**Return value**
Returns 1 if it succeeds and –1 if an error occurs. If any argument’s value is null, Update returns null. If there is no DataWindow object assigned to the DataWindow control or DataStore, this method returns 1.

**Usage**
In PowerBuilder, you must use the SetTrans or the SetTransObject method to specify the database connection before the Update method will execute. When you use SetTransObject, the more efficient of the two, you must do your own transaction management, which includes issuing the SQL COMMIT or ROLLBACK statement to finalize the update.

**Test success/failure code**
It is good practice to test the success/failure code after calling Update. You can also verify the number of rows inserted, updated, and deleted by a DataWindow update by examining the values of the arguments of the UpdateEnd event.

By default, Update resets the update flags after successfully completing the update. However, you can prevent the flags from being reset until you perform other validations and commit the changes. When you are satisfied with the update, call ResetUpdate to clear the flags so that items are no longer marked as modified.

**Use SetTransObject when resetflag is False**
You would typically use SetTransObject, not SetTrans, to specify the transaction object for the DataWindow control or DataStore when you plan to update with the resetflag argument set to false. Only SetTransObject allows you to control when changes are committed.

If you want to update several tables in one DataWindow control or DataStore, you can use Modify to change the Update property of columns in each table. To preserve the status flags of the rows and columns, set the resetflag argument to false. Because the updates all occur in the same DataWindow control or DataStore, you cannot allow the flags to be cleared until all the tables have used them. When all the updates are successfully completed and committed, you can call ResetUpdate to clear the changed flags in the DataWindow. For an example of this technique, see Modify.
If you are updating multiple DataWindow controls or DataStores as part of one transaction, set the resetflag argument to false. This will prevent the DataWindow from “forgetting” which rows to update in case one of the updates fails. You can roll back, try to correct the situation, and update again. Once all of the DataWindows have been updated successfully, use COMMIT to finalize the transaction and use ResetUpdate to reset the DataWindow’s status flags.

If you call Update with the resetflag argument set to false and do not call ResetUpdate, the DataWindow will attempt to issue the same SQL statements again the next time you call Update.

**Caution**
If you call Update in an ItemChanged event, be sure to set the accept argument to false to avoid an endless loop and a stack fault. Because AcceptText triggers an ItemChanged event, you cannot call it in that event (see AcceptText).

If you call Update in the ItemChanged event, then the item's old value is updated in the database, not the newly entered value. The newly entered value in the edit control is still being validated and does not become the item value until the ItemChanged event is successfully completed. If you want to include the new value in an update in the ItemChanged event, use the appropriate SetItem method first.

**Apply GetChanges after deleting rows in a distributed application**
If a DataWindow or data store is populated using SetChanges or SetFullState, and an Update is done that includes deleted rows, the deleted rows remain in the delete buffer until a subsequent GetChanges is applied to the DataWindow or data store.

**Web DataWindow client control**
Calling Update in the client control causes changed data to be passed to the server and updated there. Data is retrieved again and the page is reloaded.

If the DataWindow object has retrieval arguments, they must be specified in the HTML.Gen.SelfLinkArgs property. For more information, see the HTML.Gen.property, the Retrieve method, and the DataWindow Programmers Guide.

All methods that reload the page perform an AcceptText before sending data back to the server. If the method fails (returns –1), this means that pending data changes were not accepted and nothing was sent back to the server. In this situation the ItemError event occurs.
Frequent updating improves performance  The Web DataWindow DataWindow client maintains the state of the server component in string form and the information is sent to the server and back again with every request. If the user hasn’t modified the data, the amount of client side state information is small. The amount of client side state information grows proportionally to the number of outstanding changes that have not been updated to the database. When the client control or a server-side script calls the Update method, the state information returns to the minimum amount, so calling Update frequently can reduce the amount of information transferred back and forth.

Web DataWindow server component  Call GetLastError and GetLastErrorString to get information about database errors that cause SetAction, Update, Retrieve, and RetrieveEx to return -1.

Web DataWindow PSWebDataWindowClass  If Retrieve or Update return -1, the OnDBError event is triggered.

Events  Update can trigger these events:

- DBError
- SQLPreview
- UpdateEnd
- UpdateStart

If AcceptText is performed, it can trigger these events:

- ItemChanged
- ItemError

Examples  This example connects to the database, specifies a transaction object for the DataWindow control with SetTransObject, and then updates the database with the changes made in dw_employee. By default, AcceptText is performed on the data in the edit control for the current row and column and the status flags are reset:

```sql
CONNECT USING SQLCA;
dw_employee.SetTransObject(SQLCA)
... // Some processing
dw_employee.Update()
```

This example connects to the database, specifies a transaction object for the DataWindow control with SetTransObject, and then updates the database with the changes made in dw_employee. The update resets the status flags but does not perform AcceptText before updating the database:

```sql
CONNECT USING SQLCA;
dw_employee.SetTransObject(SQLCA)
... // Some processing
dw_Employee.Update(false, true)
```
As before, this example connects to the database, specifies a transaction object for the DataWindow control with SetTransObject, and then updates the database with the changes made in dw_employee. After Update is executed, the example checks the return code and, depending on the success of the update, executes a COMMIT or ROLLBACK:

```plaintext
integer rtn

CONNECT USING SQLCA;
dw_employee.SetTransObject(SQLCA)
rtn = dw_employee.\texttt{Update}()

IF rtn = 1 THEN
  COMMIT USING SQLCA;
ELSE
  ROLLBACK USING SQLCA;
END IF
```

CHAPTER 10  Methods for Graphs in the DataWindow Control

About this chapter
This chapter documents the methods that you can use to manipulate DataWindow graphs in the PowerBuilder and Web environments. You will find syntax, notes, and examples for both environments.

Other methods for DataWindows and DataStores are in a separate chapter.

Contents
The graph methods are in alphabetical order.

CategoryCount
Description
Counts the number of categories on the category axis of a graph.

Applies to
PowerBuilder DataWindow  DataWindow control
DataWindow Web ActiveX  DataWindow control

Syntax
PowerBuilder

integer dwcontrol.CategoryCount ( string graphcontrol )

Web ActiveX

number dwcontrol.CategoryCount ( string graphcontrol )

Argument  Description
----------  ----------------------------------------

dwcontrol       A reference to a DataWindow control containing the graph

graphcontrol    A string whose value is the name of the graph in the DataWindow for which you want the number of categories

Return value
Returns the count if it succeeds and -1 if an error occurs. If any argument’s value is null, CategoryCount returns null.

Examples
These statements get the number of categories in the graph gr_revenues in the DataWindow control dw_findata:

    integer li_count
    li_count = &
        dw_findata.CategoryCount("gr_revenues")
**CategoryName**

**Description**
Obtains the category name associated with the specified category number.

**Applies to**
- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**  DataWindow control

**Syntax**

**PowerBuilder**

```powerbuilder
string dwcontrol.CategoryName ( string graphcontrol, integer categorynumber )
```

**Web ActiveX**

```javascript
string dwcontrol.CategoryName ( string graphcontrol, number categorynumber )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow for which you want the name of a specific category</td>
</tr>
<tr>
<td>categorynumber</td>
<td>The number of the category for which you want the name</td>
</tr>
</tbody>
</table>

**Return value**

Returns the name of category `categorynumber` in the graph named in `graphcontrol`. If an error occurs, it returns the empty string (""). If any argument’s value is null, `CategoryName` returns null.

**Usage**
Categories are numbered consecutively, from 1 to the value returned by `CategoryCount`. When you delete a category, the categories are renumbered to keep the numbering consecutive. You can use `CategoryName` to find out the named category associated with a category number.

**Examples**
These statements obtain the name of category 5 in the graph `gr_revenues` in the DataWindow control `dw_findata`:

```powerbuilder
string ls_name
ls_name = &
    dw_findata.CategoryName("gr_revenues", 5)
```

**See also**
- CategoryCount
- SeriesName

---

**See also**

- DataCount
- SeriesCount
CHAPTER 10   Methods for Graphs in the DataWindow Control

**Clipboard**

Description: Replaces the contents of the system clipboard with a bitmap image of a graph. You can paste the image into other applications.

Applies to:
- PowerBuilder DataWindow DataWindow control
- DataWindow Web ActiveX DataWindow control

Syntax:
- **PowerBuilder**
  - integer dwcontrol.Clipboard( string graphcontrol )

- **Web ActiveX**
  - number dwcontrol.Clipboard( string graphcontrol )

Return value: Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, Clipboard returns null.

Examples:
This statement copies the graph gr_employees in the DataWindow control dw_emp_data to the clipboard:

dw_emp_data.Clipboard("gr_employees")

See also:
- Clipboard in the PowerScript Reference
- Copy

**DataCount**

Description: Reports the number of data points in the specified series in a graph.

Applies to:
- PowerBuilder DataWindow DataWindow control
- DataWindow Web ActiveX DataWindow control

Syntax:
- **PowerBuilder**
  - long dwcontrol.DataCount( string graphcontrol, string seriesname )

- **Web ActiveX**
  - number dwcontrol.DataCount( string graphcontrol, string seriesname )

DataWindow Reference 923
FindCategory

Description
Obtains the number of a category in a graph when you know the category’s label. The category values label the category axis.

Applies to
PowerBuilder DataWindow DataWindow control
DataWindow Web ActiveX DataWindow control

Syntax
PowerBuilder

integer dwcontrol.FindCategory ( string graphcontrol, date categoryvalue )
integer dwcontrol.FindCategory ( string graphcontrol, datetime categoryvalue )
integer dwcontrol.FindCategory ( string graphcontrol, double categoryvalue )
integer dwcontrol.FindCategory ( string graphcontrol, string categoryvalue )
integer dwcontrol.FindCategory ( string graphcontrol, time categoryvalue )

Web ActiveX

number dwcontrol.FindCategory ( string graphcontrol, any categoryvalue )
CHAPTER 10  Methods for Graphs in the DataWindow Control

**FindCategory**

**Description**
Returns the number of the category named in `categoryvalue` in the graph. If an error occurs, `FindCategory` returns -1. If any argument’s value is null, `FindCategory` returns null.

**Usage**
Most of the category manipulation functions require a category number, rather than a name. However, when you delete and insert categories, existing categories are renumbered to keep the numbering consecutive. Use `FindCategory` when you know only a category’s label or when the numbering might have changed.

**Examples**
These statements obtain the number of the category named Qty in the graph gr_computers in the DataWindow control dw_equipment:

```powerbuilder
integer CategoryNbr
CategoryNbr = &dw_equipment.FindCategory("gr_computers", "Qty")
```

<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td><code>graphcontrol</code></td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td><code>categoryvalue</code></td>
<td>A value that is the category for which you want the number. The value you specify must be the same datatype as the datatype of the category axis.</td>
</tr>
</tbody>
</table>

**FindSeries**

**Description**
Obtains the number of a series in a graph when you know the series’ name.

**Applies to**

- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**   DataWindow control

**Syntax**

**PowerBuilder**

```powerbuilder
type dwcontrol.FindSeries( string graphcontrol, string seriesname )
```

**Web ActiveX**

```powerbuilder
type dwcontrol.FindSeries( string graphcontrol, string seriesname )
```

DataWindow Reference 925
GetData

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesname</td>
<td>A string whose value is the name of the series for which you want the number</td>
</tr>
</tbody>
</table>

Return value

Returns the number of the series named in `seriesname` in the graph. If an error occurs, `FindSeries` returns -1. If any argument’s value is null, `FindSeries` returns null.

Usage

Most of the series manipulation functions require a series number, rather than a name. Use `FindSeries` when you know only a series’ name or when the numbering might have changed.

Examples

These statements obtain the number of the series named PCs in the graph `gr_computers` in the DataWindow control `dw_equipment` and store it in `SeriesNbr`:

```powershell
integer SeriesNbr
SeriesNbr = &
dw_equipment.FindSeries("gr_computers", "PCs")
```

See also

`FindCategory`

---

**GetData**

**Description**

Gets the value of a data point in a series in a graph when the values axis has numeric values.

For handling all datatypes and for getting values in the DataWindow Web ActiveX, see `GetDataValue`.

**Applies to**

*PowerBuilder DataWindow*  DataWindow control

**Syntax**

```powershell
PowerBuilder
double dwcontrol.GetData ( string graphcontrol, integer seriesnumber, long datapoint, { grDataType datatype } )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
</tbody>
</table>
Return value
Returns the value of the data in `datapoint` if it succeeds, 0 if the series does not exist, and -1 if an error occurs. If any argument's value is null, `GetData` returns null.

Usage
You can use `GetData` only for graphs whose values axis is numeric. For graphs with other types of values axes, use the `GetDataValue` method instead.

Examples
These statements obtain the data value of data point 3 in the series named Costs in the graph `gr_computers` in the DataWindow control `dw_equipment`:

```powerbuilder
integer SeriesNbr
double data_value

// Get the number of the series.
SeriesNbr = &
dw_equipment.FindSeries("gr_computers", "Costs")
data_value = dw_equipment.GetData( &
"gr_computers", SeriesNbr, 3)
```

These statements obtain the x value of the data point in the scatter graph `gr_sales_yr` in the DataWindow `dw_sales` and store it in `data_value`:

```powerbuilder
integer SeriesNbr, ItemNbr
double data_value

dw_sales.ObjectAtPointer("gr_sales_yr", SeriesNbr, &
ItemNbr)
data_value = dw_sales.GetData("gr_sales_yr", &
SeriesNbr, ItemNbr, xValue!)
```

See also
`FindSeries`
`GetDataValue`
`ObjectAtPointer`
**GetDataDateVariable**

**Description**
Returns the value associated with a data point in a graph in a DataWindow object when the values axis has the date datatype. You must call GetDataDate first to retrieve the line style information. (GetDataDate is based on GetDataValue and is documented in that entry.)

**Applies to**
*DataWindow* *Web ActiveX*  
DataWindow control

**Syntax**
```powerbuilder
Date dwcontrol.GetDataDateVariable ()
```

**Argument**  
**Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

**Return value**
Returns a date value associated with a data point in a graph.

**Usage**
To find out the value of a data point, call one of the GetData methods to retrieve the information, then immediately afterward, call one of the GetDataVariable methods and examine the return value.

<table>
<thead>
<tr>
<th>For a values axis of type</th>
<th>Call this method to set up the value</th>
<th>Then call this method to return the value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date, DateTime, or time</td>
<td>GetDataDate</td>
<td>GetDataDateVariable</td>
</tr>
<tr>
<td>Number or double</td>
<td>GetDataNumber</td>
<td>GetDataNumberVariable</td>
</tr>
<tr>
<td>String</td>
<td>GetDataString</td>
<td>GetDataStringVariable</td>
</tr>
</tbody>
</table>

For information on the GetData methods, see GetDataValue.

**See also**
GetDataValue
**GetDataLabelling**

**Description**
Determines whether the data at a given data point is labeled in a DirectX 3D graph.

**Applies to**
DataWindow control

**Syntax**
```
integer dwcontrol.GetDataLabelling (string graphcontrol, string series, int datapoint, REF boolean value)
```

**Argument** | **Description**
--- | ---
*dwcontrol* | A reference to the DataWindow control containing the graph.
*graphcontrol* | A string whose value is the name of the graph in the DataWindow control.
*series* | The string that identifies the series in which you want the data labelling value.
*datapoint* | The data point for which you want to obtain a label.
*value* | Boolean passed by reference to indicate whether the data point has a label.

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, GetDataLabelling returns null.

**Usage**
GetDataLabelling determines whether a data label is set for data points from DirectX 3D Area, Bar, Col, or Line graphs. You cannot use this method with DirectX 3D Pie graphs.

**Examples**
In a DataWindow Clicked event, these statements obtain the number of the series and data point clicked by the user and determine whether the label is set for that data point.

```
integer SeriesNbr, ItemNbr
boolean refB
grObjectType clickedtype

// Get the number of the series and data point
clickedtype = this.ObjectAtPointer("gr_1", & SeriesNbr, ItemNbr)

// Get data label
this.GetDataLabelling("gr_1", SeriesNbr, & ItemNbr, refB)
```

**See also**
GetSeriesLabelling
SetDataLabelling
SetSeriesLabelling
**GetDataNumberVariable**

*Description*
Returns the value associated with a data point in a graph in a DataWindow object when the values axis has a numeric datatype. You must call GetDataNumber first to retrieve the line style information. (GetDataNumber is based on GetDataValue and is documented in that entry.)

*Applies to*
- *DataWindow Web ActiveX*  DataWindow control

*Syntax*

```powerbuilder
Web ActiveX

number dwcontrol.GetDataNumberVariable( )
```

*Argument Description*

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

*Return value*
Returns a number value associated with a data point in a graph.

*Usage*
To find out the value of a data point, call one of the GetData methods to retrieve the information, then immediately afterward, call one of the GetDataVariable methods and examine the return value.

<table>
<thead>
<tr>
<th>For a values axis of type</th>
<th>Call this method to set up the value</th>
<th>Then call this method to return the value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date, DateTime, or time</td>
<td>GetDataDate</td>
<td>GetDataDateVariable</td>
</tr>
<tr>
<td>Number or double</td>
<td>GetDataNumber</td>
<td>GetDataNumberVariable</td>
</tr>
<tr>
<td>String</td>
<td>GetDataString</td>
<td>GetDataStringVariable</td>
</tr>
</tbody>
</table>

For information on the GetData methods, see GetDataValue.

*See also*
GetDataValue

---

**GetDataPieExplode**

*Description*
Reports the percentage of the pie graph’s radius that a pie slice is moved away from the center of the pie graph. An exploded slice is moved away from the center of the pie in order to draw attention to the data.

*Applies to*
- *PowerBuilder DataWindow*  DataWindow control
- *DataWindow Web ActiveX*  DataWindow control

*Syntax*

```powerbuilder
PowerBuilder

integer dwcontrol.GetDataPieExplode( string graphcontrol, integer series, integer datapoint, REF integer percentage )
```

930  PowerBuilder
**Web ActiveX**

```plaintext
number dwcontrol.GetDataPieExplode ( string graphcontrol, number series, number datapoint )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control containing the graph</td>
</tr>
<tr>
<td><code>graphcontrol</code></td>
<td>A string whose value is the name of the graph in the DataWindow control</td>
</tr>
<tr>
<td><code>series</code></td>
<td>The number that identifies the series</td>
</tr>
<tr>
<td><code>datapoint</code></td>
<td>The number of the exploded data point (that is, the pie slice)</td>
</tr>
<tr>
<td><code>percentage</code></td>
<td>An integer variable in which you want to store the percentage that the pie slice is exploded</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, `GetDataPieExplode` returns null.

**Examples**

This example reports the percentage that a pie slice is exploded when the user clicks on that slice. The code checks whether the graph is a pie graph using the property `GraphType`. It then finds out whether the user clicked on a pie slice by checking the series and data point values set by `ObjectAtPointer`. The script is for the `DoubleClicked` event of a graph control:

```plaintext
integer series, datapoint
groObjectType clickedtype
integer percentage

percentage = 50
IF (This.GraphType <> PieGraph! and &
    This.GraphType <> Pie3D!) THEN RETURN
clickedtype = This.ObjectAtPointer(series, &
    datapoint)

IF (series > 0 and datapoint > 0) THEN
    This.GetDataPieExplode("gr_sales_yr", series, &
        datapoint, percentage)
    MessageBox("Explosion Percentage", &
        "Data point " + This.CategoryName(datapoint) &
        " in series " + This.SeriesName(series) &
        " is exploded " + String(percentage) + ")
END IF
```

**See also**

- `GetDataPieExplodePercentage`
- `SetDataPieExplode`
**GetDataPieExplodePercentage**

**Description**
Returns the percentage value that a slice is exploded in a pie graph in a DataWindow object. You must call `GetDataPieExplode` first to retrieve the information and then call this method to get the value.

**Applies to**
DataWindow Web ActiveX  DataWindow control

**Syntax**
```powershell
Web ActiveX
number dwcontrol.GetDataPieExplodePercentage ()
```

**Argument** | **Description**
---|---
dwcontrol | A reference to a DataWindow control containing the graph

**Return value**
Returns a number specifying how much the pie slice is exploded.

**Usage**
To find out the percentage of the pie graph's radius that a pie slice is moved away from the center of the pie graph, call `GetDataPieExplode` to retrieve the information, then immediately afterward, call `GetDataPieExplodePercentage` and examine the return value.

**See also**
GetDataPieExplode
SetDataPieExplode

---

**GetDataStringVariable**

**Description**
Returns the value associated with a data point in a graph in a DataWindow object when the values axis has the string datatype. You must call `GetDataString` first to retrieve the line style information. (`GetDataString` is based on `GetDataValue` and is documented in that entry.)

**Applies to**
DataWindow Web ActiveX  DataWindow control

**Syntax**
```powershell
Web ActiveX
string dwcontrol.GetDataStringVariable ()
```

**Argument** | **Description**
---|---
dwcontrol | A reference to a DataWindow control containing the graph

**Return value**
String. Returns a string value associated with a data point in a graph.

**Usage**
To find out the value of a data point, call one of the `GetData` methods to retrieve the information, then immediately afterward, call one of the `GetDataVariable` methods and examine the return value.
For a values axis of type | Call this method to set up the value | Then call this method to return the value
---|---|---
Date, DateTime, or time | GetDataDate | GetDataDateVariable
Number or double | GetDataNumber | GetDataNumberVariable
String | GetDataString | GetDataStringVariable

For information on the GetData methods, see GetDataValue.

See also GetDataValue

**GetDataStyle**

Finds out the appearance of a data point in a graph. Each data point in a series can have individual appearance settings. There are different syntaxes, depending on what settings you want to check.

<table>
<thead>
<tr>
<th>To get the</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data point’s colors (called GetDataStyleColor in JavaScript)</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>Line style and width used by the data point (called GetDataStyleLine in JavaScript)</td>
<td>Syntax 2</td>
</tr>
<tr>
<td>Fill pattern for the data point (called GetDataStyleFill in JavaScript)</td>
<td>Syntax 3</td>
</tr>
<tr>
<td>Symbol for the data point (called GetDataStyleSymbol in JavaScript)</td>
<td>Syntax 4</td>
</tr>
</tbody>
</table>

GetDataStyle provides information about a single data point. The series to which the data point belongs has its own style settings. In general, the style values for the data point are the same as its series’ settings. Use SetDataStyle to change the style values for individual data points. Use GetSeriesStyle and SetSeriesStyle to get and set style information for the series.

The graph stores style information for properties that do not apply to the current graph type. For example, you can find out the fill pattern for a data point or a series in a 2-dimensional line graph, but that fill pattern will not be visible.
**GetDataStyle**

**Syntax 1**

For the colors of a data point

Description
Obtains the colors associated with a data point in a graph.

 Applies to
*PowerBuilder DataWindow* DataWindow control

*DataWindow Web ActiveX* DataWindow control

Syntax

**PowerBuilder**

```
integer dwcontrol.GetDataStyle ( string graphcontrol, integer seriesnumber, integer datapointnumber, grColorType colortype, REF long colorvariable )
```

**Web ActiveX**

```
number dwcontrol.GetDataStyleColor ( string graphcontrol, number seriesnumber, number datapointnumber, number colortype )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number of the series in which you want the color of a data point.</td>
</tr>
<tr>
<td>datapointnumber</td>
<td>The number of the data point for which you want the color.</td>
</tr>
<tr>
<td>colortype</td>
<td>A value of the grColorType enumerated datatype (in PowerBuilder) or an integer (in JavaScript) specifying the aspect of the data point for which you want the color. For a list of values, see grColorType on page 481.</td>
</tr>
<tr>
<td>colorvariable</td>
<td>In PowerBuilder, a long variable in which you want to store the color.</td>
</tr>
</tbody>
</table>

Return value
Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, GetDataStyle stores an RGB color value in colorvariable. If any argument’s value is null, GetDataStyle returns null.

Examples
This example gets the background color used for data point 6 in the series entered in the SingleLineEdit sle_series in the DataWindow graph gr_emp_data. It stores the color value in the variable color_nbr:

```
long color_nbr
integer SeriesNbr

// Get the number of the series
SeriesNbr = &
        FindSeries("gr_emp_data", sle_series.Text)
```
// Get the color
dw_emp_data.GetDataStyle("gr_emp_data", &
    SeriesNbr, 6, Background!, color_nbr)

See also
FindSeries
GetSeriesStyle
SetDataStyle
SetSeriesStyle

Syntax 2
For the line style and width used by a data point

Description
Obtains the line style and width for a data point in a graph.

Applies to
PowerBuilder DataWindow   DataWindow control
DataWindow Web ActiveX   DataWindow control

Syntax
PowerBuilder

    integer dwcontrol.GetDataStyle ( string graphcontrol, integer
    seriesnumber, integer datapointnumber, REFLineStyle linestyle, REF
    integer linewidth )

Web ActiveX

    number dwcontrol.GetDataStyleLine ( string graphcontrol, number
    seriesnumber, number datapointnumber )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number of the series in which you want the line style and width of a data point.</td>
</tr>
<tr>
<td>datapointnumber</td>
<td>The number of the data point for which you want the line style and width.</td>
</tr>
<tr>
<td>linestyle</td>
<td>In PowerBuilder, a variable of typeLineStyle in which you want to store the line style. For the Web ActiveX, call GetDataStyleLineStyle to get the value. For a list of line style values, see LineStyle on page 484.</td>
</tr>
<tr>
<td>linewidth</td>
<td>In PowerBuilder, an integer variable in which you want to store the width of the line. The width is measured in pixels. For the Web ActiveX, call GetDataStyleLineWidth to get the value.</td>
</tr>
</tbody>
</table>
**GetDataStyle**

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, for the specified series and data point, GetDataStyle stores its line style in linestyle and the line’s width in linewidth. If any argument’s value is null, GetDataStyle returns null.

**Examples**
This example gets the line style and width for data point 6 in the series entered in the SingleLineEdit sle_series in the graph gr_depts in the DataWindow control dw_employees. The information is stored in the variables line_style and line_width:

```plaintext
integer SeriesNbr, line_width
LineStyle line_style

// Get the number of the series
SeriesNbr = dw_employees.FindSeries(&"gr_depts", sle_series.Text)

// Get the line style and width
dw_employees.GetDataStyle("gr_depts", SeriesNbr, &6, line_style, line_width)
```

**See also**

GetSeriesStyleLineWidth
GetSeriesStyle
SetDataStyle
SetSeriesStyle

---

**Syntax 3**
**For the fill pattern of a data point**

**Description**
Obtains the fill pattern of a data point in a graph.

**Applies to**
*PowerBuilder DataWindow* DataWindow control

*DataWindow Web ActiveX* DataWindow control

**Syntax**

**PowerBuilder**

```plaintext
integer dwcontrol.GetDataStyle ( string graphcontrol, integer seriesnumber, integer datapoinumber, REF FillPattern fillvariable )
```

**Web ActiveX**

```plaintext
number dwcontrol.GetDataStyleFill ( string graphcontrol, number seriesnumber, number datapointnumber )
```
DataWindow Reference

CHAPTER 10  Methods for Graphs in the DataWindow Control

**GetDataStyle**

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, **GetDataStyle** stores a value of the FillPattern enumerated datatype representing the fill pattern used for the specified data point. If any argument's value is null, **GetDataStyle** returns null.

**Examples**

This example gets the pattern used to fill data point 6 in the series entered in the SingleLineEdit sle_series in the graph gr_depts in the DataWindow control dw_employees. The information is assigned to the variable data_pattern:

```powershell
integer SeriesNbr
FillPattern data_pattern

// Get the number of the series
SeriesNbr = dw_employees.FindSeries("gr_depts", & sline_series.Text)

// Get the pattern
dw_employees.GetDataStyle("gr_depts", SeriesNbr, & 6, data_pattern)
```

**Argument** | **Description**
---|---
**dwcontrol** | A reference to the DataWindow control containing the graph.
**graphcontrol** | A string whose value is the name of the graph in the DataWindow control.
**seriesnumber** | The number of the series in which you want the fill pattern of a data point.
**datapointnumber** | The number of the data point for which you want the fill pattern.
**fillvariable** | In PowerBuilder, a variable of type FillPattern in which you want to store the fill pattern value. In the Web ActiveX, call GetDataStyleFillPattern to get the value. For a list of values, see FillPattern on page 480.

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, **GetDataStyle** stores a value of the FillPattern enumerated datatype representing the fill pattern used for the specified data point. If any argument’s value is null, **GetDataStyle** returns null.

**See also**

FindSeries
GetDataStyleFillPattern
GetSeriesStyle
SetDataStyle
SetSeriesStyle
GetDataStyle

Syntax 4

For the symbol of a data point

Description

Obtains the symbol of a data point in a graph.

Applies to

*PowerBuilder* DataWindow   DataWindow control

*DataWindow Web ActiveX*   DataWindow control

Syntax

**PowerBuilder**

\[
\text{integer} \ dwcontrol.\text{GetDataStyle} (\ \text{string} \ graphcontrol, \ \text{integer} \ seriesnumber, \ \text{integer} \ datapointnumber, \ \text{REF} \ \text{grSymbolType} \ symbolvariable)
\]

**Web ActiveX**

\[
\text{number} \ dwcontrol.\text{GetDataStyleSymbol} (\ \text{string} \ graphcontrol, \ \text{number} \ seriesnumber, \ \text{number} \ datapointnumber)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number of the series in which you want the symbol type of a data point.</td>
</tr>
<tr>
<td>datapointnumber</td>
<td>The number of the data point for which you want the symbol type.</td>
</tr>
<tr>
<td>symbolvariable</td>
<td>In PowerBuilder, a variable of type grSymbolType in which you want to store the symbol type.</td>
</tr>
<tr>
<td></td>
<td>In the Web ActiveX, call GetDataStyleSymbolValue to get the value instead of using a reference variable.</td>
</tr>
<tr>
<td></td>
<td>For a list of values, see grSymbolType on page 483.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. Stores, according to the type of symbolvariable, a value of that enumerated datatype representing the symbol used for the specified data point. If any argument’s value is null, GetDataStyle returns null.

Examples

These statements store the symbol for a data point in the variable symbol_type. The data point is the sixth point in the series named in the SingleLineEdit sle_series in the graph gr_depts in the DataWindow control dw_employees:

```powerbuilder
integer SeriesNbr
grSymbolType symbol_type

// Get the number of the series
SeriesNbr = dw_employees.FindSeries("gr_depts", & sle_series.Text)
```
// Get the symbol  
  dw_employees.GetDataStyle(”gr_depts”, SeriesNbr, &  
                6, symbol_type)

SetSeriesStyle

### GetDataStyleColorValue

**Description**  
Returns the color value associated with a data point in a graph in a DataWindow object. You must call GetDataStyleColor first to retrieve the color information. (See GetDataStyle for information about this method.)

**Applies to**  
DataWindow Web ActiveX  
DataWindow control

**Syntax**  
Web ActiveX  
number dwcontrol.GetDataStyleColorValue ( )

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

**Return value**  
Returns an RGB color value.

**Usage**  
To find out the color associated with a data point, call GetDataStyleColor to retrieve the information, then immediately afterward, call GetDataStyleColorValue and examine the return value.

The color for a data point overrides the color setting for the series.

See also  
GetDataStyle

### GetDataStyleFillPattern

**Description**  
Returns the fill pattern associated with a data point in a graph in a DataWindow object. You must call GetDataStyleFill first to retrieve the fill information. (See GetDataStyle for information about this method.)

**Applies to**  
DataWindow Web ActiveX  
DataWindow control
GetDataStyleFillPattern

Syntax

```powershell
number dwcontrol.GetDataStyleFillPattern ( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

Return value

Returns an integer representing the fill pattern.

For a list of values and their meanings, see FillPattern on page 480.

Usage

To find out the fill pattern associated with a data point, call GetDataStyleFill to retrieve the information, then immediately afterward, call GetDataStyleFillPattern and examine the return value.

The fill pattern for a data point overrides the fill pattern setting for the series.

See also

GetDataStyle

GetDataStyleLineStyle

Description

Returns the line style associated with a data point in a graph in a DataWindow object. You must call GetDataStyleLine first to retrieve the line style information. (See GetDataStyle for information about this method.)

Applies to

DataWindow Web ActiveX DataWindow control

Syntax

```powershell
Web ActiveX
datacontrol.GetDataStyleLineStyle ( )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datacontrol</td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

Return value

Returns an integer representing the line style.

For a list of values and their meanings, see LineStyle on page 484.

Usage

To find out the line width or line style associated with a data point, call GetDataStyleLine to retrieve the information, then immediately afterward, call GetDataStyleLineWidth and GetDataStyleLineStyle and examine the return values.

The line style for a data point overrides the setting for the series.

See also

GetDataStyle
CHAPTER 10  Methods for Graphs in the DataWindow Control

GetDataStyleLineWidth

Description
Returns the line width associated with a data point in a graph in a DataWindow object. You must call GetDataStyleLine first to retrieve the line style information. (See GetDataStyle for information about this method.)

Applies to
DataWindow Web ActiveX  DataWindow control

Syntax
Web ActiveX

number dwcontrol.GetDataStyleLineWidth ( )

Return value
Returns the width of the line in pixels.

Usage
To find out the line width or line style associated with a data point, call GetDataStyleLine to retrieve the information, then immediately afterward, call GetDataStyleLineWidth and GetDataStyleLineStyle and examine the return values.

The line width for a data point overrides the setting for the series.

See also
GetDataStyle

GetDataStyleSymbolValue

Description
Returns the symbol associated with a data point in a graph in a DataWindow object. You must call GetDataStyleSymbol first to retrieve the symbol information. (See GetDataStyle for information about this method.)

Applies to
DataWindow Web ActiveX  DataWindow control

Syntax
Web ActiveX

number dwcontrol.GetDataStyleSymbolValue ( )

Return value
Returns an integer representing data point’s symbol. For a list of values and their meanings, see grSymbolType on page 483.
**GetDataTransparency**

**Usage**

To find out the symbol associated with a data point, call GetDataStyleSymbol to retrieve the information, then immediately afterward, call GetDataStyleSymbolValue and examine the return value.

The symbol for a data point overrides the setting for the series.

**See also**

GetDataStyle

**GetDataTransparency**

**Description**

Obtains the transparency percentage of a data point in a DirectX 3D graph (those with 3D rendering).

** Applies to **

DataWindow control

**Syntax**

integer dwcontrol.GetDataTransparency ( string graphcontrol, integer seriesnumber, int datapoint, REF int transparency)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number that identifies the series from which you want data.</td>
</tr>
<tr>
<td>datapoint</td>
<td>The number of the data point for which you want the transparency value.</td>
</tr>
<tr>
<td>transparency</td>
<td>Integer value for percent transparency. A value of 0 means that the data point is opaque and a value of 100 means that it is completely transparent.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, GetDataTransparency returns null.

**Usage**

GetDataTransparency retrieves data from any DirectX 3D graph (those with 3D rendering).

**Examples**

These statements obtain the transparency percentage of data point 3 in the series named Costs in the graph gr_computers in the DataWindow control dw_equipment:

```powerbuilder
integer SeriesNbr, rtn, transp_value

// Get the number of the series.
SeriesNbr = dw_equipment.FindSeries( &
   "gr_computers", "Costs")
```

942  PowerBuilder
CHAPTER 10  Methods for Graphs in the DataWindow Control

rtn = dw_equipment.GetDataTransparency( "gr_computers", SeriesNbr, 3, transp_value)

GetDataValue

Description
Obtains the value of a data point in a series in a graph.
In the Web ActiveX, there are several methods, each handling a different datatype.

Applies to
PowerBuilder DataWindow  DataWindow control
DataWindow Web ActiveX  DataWindow control

Syntax

PowerBuilder

integer dwcontrol.GetDataValue ( string graphcontrol, integer seriesnumber, long datapoint, REF date datavariable {}, grDataType XorY )
integer dwcontrol.GetDataValue ( string graphcontrol, integer seriesnumber, long datapoint, REF datetime datavariable {}, grDataType XorY )
integer dwcontrol.GetDataValue ( string graphcontrol, integer seriesnumber, long datapoint, REF double datavariable {}, grDataType XorY )
integer dwcontrol.GetDataValue ( string graphcontrol, integer seriesnumber, long datapoint, REF string datavariable {}, grDataType XorY )
integer dwcontrol.GetDataValue ( string graphcontrol, integer seriesnumber, long datapoint, REF time datavariable {}, grDataType XorY )

Web ActiveX

number dwcontrol.GetDataDate ( string graphcontrol, number seriesnumber, number datapoint, number XorY )
number dwcontrol.GetDataNumber ( string graphcontrol, number seriesnumber, number datapoint, number XorY )
number dwcontrol.GetDataString ( string graphcontrol, number seriesnumber, number datapoint, number XorY )
**GetDataValue**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number that identifies the series from which you want data.</td>
</tr>
<tr>
<td>datapoint</td>
<td>The number of the data point for which you want the value.</td>
</tr>
<tr>
<td>datavariable</td>
<td>The name of a variable that will hold the data value. The variable's datatype can be date, DateTime, double, string, or time. The variable must have the same datatype as the values axis of the graph. In the Web ActiveX, call the GetDataDateVariable, GetDataNumberVariable, or GetDataStringVariable to get the value, instead of using the reference variable.</td>
</tr>
<tr>
<td>xory</td>
<td>A value of the grDataType enumerated datatype (in PowerBuilder) or an integer (in the Web ActiveX) specifying whether you want the x or y value of the data point in a scatter graph. For values, see grDataType on page 482.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, GetDataValue returns null.

**Usage**

GetDataValue retrieves data from any graph. The data is stored in datavariable, whose datatype must match the datatype of the graph’s values axis, or returned by a method that corresponds to the axis datatype. If the values axis is numeric, you can also use the GetData function.

Calling GetDataValue when the datatype of datavariable is not the same as the datatype of the data produces undefined results.

If a variable’s datatype is non-numeric and the datatype of datavariable is double, GetDataValue returns the number of the datapoint in datavariable.

If a variable’s datatype is date, time, or DateTime, GetDataValue returns 1 when the datatype of datavariable is any of those datatypes. However, if the variable’s datatype is time and the datatype of datavariable is date, GetDataValue returns 00/00/00 in datavariable, and if the variable’s datatype is date and the datatype of datavariable is time, GetDataValue returns 00:00:00 in datavariable.
Examples

These statements obtain the data value of data point 3 in the series named Costs in the graph gr_computers in the DataWindow control dw_equipment:

```plaintext
integer SeriesNbr, rtn
double data_value

// Get the number of the series.
SeriesNbr = dw_equipment.FindSeries( &
    "gr_computers", "Costs")
rtn = dw_equipment.GetDataValue( &
    "gr_computers", SeriesNbr, 3, data_value)
```

See also
FindSeries
ObjectAtPointer

---

**GetSeriesLabelling**

**Description**
Determines whether the data for a given series is labeled in a DirectX 3D graph.

**Applies to**
DataWindow control

**Syntax**
`integer dwcontrol.GetSeriesLabelling (string graphcontrol, string series, REF boolean value)`

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to the DataWindow control containing the graph.
`graphcontrol` | A string whose value is the name of the graph in the DataWindow control.
`series` | The string that names the series in which you want the series label setting.
`value` | A boolean passed by reference to indicate whether the series has labels.

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, GetSeriesLabelling returns null.

**Usage**
GetSeriesLabelling retrieves the data from DirectX 3D Area, Bar, Col, or Line graphs. You cannot use this method with DirectX 3D Pie graphs.

**Examples**
These statements obtain the number of the series and data point for the graph gr_1 in the DataWindow control dw_employee and then get the series label setting.

```plaintext
integer SeriesNbr, ItemNbr
```
GetSeriesStyle

boolean refB
string ls_SeriesName
grObjectType clickedtype

// Get the number of the series and datapoint
clickedtype = this.ObjectAtPointer("gr_1", &
    SeriesNbr, ItemNbr)

// Get the name of series
ls_SeriesName = dw_employee.SeriesName("gr_1", &
    SeriesNbr)

// Get Series label
dw_employee.GetSeriesLabelling("gr_1", &
    ls_SeriesName, refB)

SetSeriesLabelling

GetSeriesStyle

Finds out the appearance of a series in a graph. The appearance settings for individual data points can override the series settings, so the values obtained from GetSeriesStyle might not reflect the current state of the graph. There are several syntaxes, depending on what settings you want.

<table>
<thead>
<tr>
<th>To</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get the series' colors</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>Web ActiveX The method is called GetSeriesStyleColor.</td>
<td></td>
</tr>
<tr>
<td>Get the line style and width used by the series</td>
<td>Syntax 2</td>
</tr>
<tr>
<td>Web ActiveX The method is called GetSeriesStyleLine.</td>
<td></td>
</tr>
<tr>
<td>Get the fill pattern for the series</td>
<td>Syntax 3</td>
</tr>
<tr>
<td>Web ActiveX The method is called GetSeriesStyleFill.</td>
<td></td>
</tr>
<tr>
<td>Get the symbol for data points in the series</td>
<td>Syntax 4</td>
</tr>
<tr>
<td>Web ActiveX The method is called GetSeriesStyleSymbol.</td>
<td></td>
</tr>
<tr>
<td>Find out if the series is an overlay (a series shown as a line on top of another graph type)</td>
<td>Syntax 5</td>
</tr>
<tr>
<td>Web ActiveX The method is called GetSeriesStyleOverlay.</td>
<td></td>
</tr>
</tbody>
</table>
GetSeriesStyle provides information about a series. The data points in the series can have their own style settings. Use SetSeriesStyle to change the style values for a series. Use GetDataStyle to get style information for a data point and SetDataStyle to override series settings and set style information for individual data points.

The graph stores style information for properties that do not apply to the current graph type. For example, you can find out the fill pattern for a data point or a series in a two-dimensional line graph, but that fill pattern will not be visible.

**Syntax 1**

*For the colors of a series*

Description

Obtains the colors associated with a series in a graph.

Applies to

PowerBuilder DataWindow  DataWindow control

DataWindow Web ActiveX  DataWindow control

**Syntax**

For PowerBuilder

\[
\text{integer} \ dwcontrol.\text{GetSeriesStyle} ( \ \text{string} \ graphcontrol, \ \text{string} \ \text{seriesname}, \ \text{grColorType} \ \text{colortype}, \ \text{REF} \ \text{long} \ \text{colorvariable})
\]

For Web ActiveX

\[
\text{number} \ dwcontrol.\text{GetSeriesStyleColor} ( \ \text{string} \ graphcontrol, \ \text{string} \ \text{seriesname}, \ \text{number} \ \text{colortype})
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesname</td>
<td>A string whose value is the name of the series for which you want the color.</td>
</tr>
<tr>
<td>colortype</td>
<td>A value of the grColorType enumerated datatype (in PowerBuilder) or an integer (for the Web ActiveX) specifying the aspect of the series for which you want the color. For a list of values, see grColorType on page 481.</td>
</tr>
<tr>
<td>colorvariable</td>
<td>In PowerBuilder, a long variable in which you want to store the color’s RGB value. For the Web ActiveX, call GetSeriesStyleColorValue to get the value.</td>
</tr>
</tbody>
</table>
**Return value**

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, stores in `colorvariable` the RGB value of the specified series and item. If any argument’s value is null, `GetSeriesStyle` returns null.

**Examples**

These statements store in the variable `color_nbr` the background color used for the series PCs in the graph `gr_computers` in the DataWindow control `dw_equipment`:

```powerbuilder
long color_nbr
// Get the color.
dw_equipment.GetSeriesStyle("gr_computers", &
  "PCs", Background!, color_nbr)
```

**See also**

- GetDataStyle
- GetSeriesStyleColorValue
- FindSeries
- GetDataStyle
- SetSeriesStyle

---

**Syntax 2**

**For the line style and width used by a series**

**Description**

Obtains the line style and width for a series in a graph.

**Applies to**

- **PowerBuilder DataWindow** DataWindow control
- **DataWindow Web ActiveX** DataWindow control

**Syntax**

**PowerBuilder**

```powerbuilder
integer dwcontrol.GetSeriesStyle ( string graphcontrol, string
  seriesname, REF LineStyle linestyle , REF integer
  linewidth )
```

**Web ActiveX**

```powerbuilder
number dwcontrol.GetSeriesLineStyle ( string graphcontrol, string
  seriesname )
```

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to the DataWindow control containing the graph.
`graphcontrol` | A string whose value is the name of the graph in the DataWindow control.
`seriesname` | A string whose value is the name of the series for which you want the line style information.
`linestyle` | In PowerBuilder, a variable of type `LineStyle` in which you want to store the line style of `seriesname`. For the Web ActiveX, call `GetSeriesLineStyle` to get the value. For a list of values, see `LineStyle` on page 484.
Return value

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, stores in linestyle a value of the LineStyle enumerated datatype and in linewidth the width of the line used for the specified series. If any argument’s value is null, GetSeriesStyle returns null.

Examples

These statements store in the variables line_style and line_width the line style and width for the series under the mouse pointer in the graph gr_product_data:

```powerbuilder
string SeriesName
integer SeriesNbr, Data_Point, line_width
LineStyle line_style
grObjectType MouseHit

MouseHit = dw_equipment.ObjectAtPointer &
  ("gr_product_data", SeriesNbr, Data_Point)

IF MouseHit = TypeSeries! THEN
  SeriesName = &
    dw_equipment.SeriesName("gr_product_data", &
      SeriesNbr)

  dw_equipment.GetSeriesStyle ("gr_product_data", &
    SeriesName, line_style, line_width)
END IF
```

SetDataStyle
SetSeriesStyle
GetSeriesStyle

Syntax 3

For the fill pattern of a series

Description
Obtains the fill pattern of a series in a graph.

Applies to

- PowerBuilder DataWindow  DataWindow control
- DataWindow Web ActiveX  DataWindow control

Syntax

PowerBuilder

\[
\text{integer } \text{dwcontrol.} \text{GetSeriesStyle} \left( \text{string } \text{graphcontrol}, \text{string } \text{seriesname}, \text{REF FillPattern } \text{fillvariable} \right)
\]

Web ActiveX

\[
\text{number } \text{dwcontrol.} \text{GetSeriesStyleFill} \left( \text{string } \text{graphcontrol}, \text{string } \text{seriesname} \right)
\]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesname</td>
<td>A string whose value is the name of the series for which you want the style information.</td>
</tr>
<tr>
<td>fillvariable</td>
<td>In PowerBuilder, a variable of type FillPattern in which you want to store the fill pattern value. For the Web ActiveX, call GetSeriesStyleFillPattern to get the value. For a list of values, see FillPattern on page 480.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, stores in fillvariable identifying the fill pattern for the specified series. If any argument’s value is null, GetSeriesStyle returns null.

Examples

This example stores in the variable data_pattern the fill pattern for the series under the pointer in the graph gr_depts in the DataWindow control dw_employees. It then sets the fill pattern for the series Total Salary in the graph gr_dept_data to that pattern:

\[
\text{string SeriesName} \\
\text{integer SeriesNbr, Data_Point} \\
\text{FillPattern data_pattern} \\
\text{grObjectType MouseHit} \\
\text{MouseHit = dw_employees.ObjectAtPointer("gr_depts", & SeriesNbr, Data_Point)} \\
\text{IF MouseHit = TypeSeries! THEN} \\
\text{    SeriesName = &} \\
\text{    dw_employees.SeriesName("gr_depts", SeriesNbr)}
\]

CHAPTER 10  Methods for Graphs in the DataWindow Control

```
dw_employees.GetSeriesStyle("gr_depts", &SeriesName, data_pattern)

gr_dept_data.SetSeriesStyle("Total Salary", &data_pattern)
```

END IF

GetDataStyle
GetSeriesStyleFillPattern
FindSeries
SetDataStyle
SetSeriesStyle

Syntax 4  For the symbol of a series

Description
Obtains the symbol used for data points in a series in a graph.

Applies to

- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**  DataWindow control

Syntax

**PowerBuilder**

```
integer dwcontrol.GetSeriesStyle ( string graphcontrol, string seriesname, REF grSymbolType symbolvariable )
```

**Web ActiveX**

```
number dwcontrol.GetSeriesStyleSymbol ( string graphcontrol, string seriesname )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesname</td>
<td>A string whose value is the name of the series for which you want the style information.</td>
</tr>
<tr>
<td>symbolvariable</td>
<td>In PowerBuilder, the variable of type grSymbolType in which you want to store the symbol value.</td>
</tr>
<tr>
<td></td>
<td>For the Web ActiveX, call GetSeriesStyleSymbolValue to get the value.</td>
</tr>
<tr>
<td></td>
<td>For a list of values, see grSymbolType on page 483.</td>
</tr>
</tbody>
</table>
GetSeriesStyle

Return value

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, stores in symbolvariable a value of the grSymbolType enumerated datatype for the symbol used for the specified series. If any argument's value is null, GetSeriesStyle returns null.

Examples

This example stores in the variable data_pattern the fill pattern for the series under the pointer in the graph gr_depts in the DataWindow control dw_employees. It then sets the fill pattern for the series Total Salary in the graph gr_dept_data to that pattern:

```powerbuilder
string SeriesName
integer SeriesNbr, Data_Point
grSymbolType symbol
grObjectTyp EmouseHit

MouseHit = dw_employees.ObjectAtPointer("gr_depts", &SeriesNbr, Data_Point)

IF MouseHit = TypeSeries! THEN
    SeriesName = &
        dw_employees.SeriesName("gr_depts", SeriesNbr)
        dw_employees.GetSeriesStyle("gr_depts", &
            SeriesName, symbol
        gr_dept_data.SetSeriesStyle("Total Salary", &
            symbol)
END IF
```

GetSeriesStyleSymbolValue
FindSeries
SetDataStyle
SetSeriesStyle

Syntax 5

For determining whether a series is an overlay

Description

Reports whether a series in a graph is an overlay—whether it is shown as a line on top of another graph type.

Applies to

PowerBuilder DataWindow DataWindow control
DataWindow Web ActiveX DataWindow control

Syntax

```powerbuilder
integer dwcontrol.GetSeriesStyle ( string graphcontrol, string
    seriesname, REF boolean overlayindicator )
```

952
CHAPTER 10 Methods for Graphs in the DataWindow Control

Web ActiveX

\[
\text{number } \text{dwcontrol}.\text{GetSeriesStyleOverlay}(\text{string } graphcontrol, \text{string } seriesname) \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{dwcontrol}</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>\text{graphcontrol}</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>\text{seriesname}</td>
<td>A string whose value is the name of the series for which you want the overlay status.</td>
</tr>
<tr>
<td>\text{overlayindicator}</td>
<td>In PowerBuilder, a boolean variable in which you want to store a value indicating whether the series is an overlay. GetSeriesStyle sets \text{overlayindicator} to true if the series is an overlay and false if it is not. For the Web ActiveX, call GetSeriesStyleOverlayValue to get the value instead of specifying the reference variable.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. In PowerBuilder, stores in \text{overlayindicator} true if the specified series is an overlay and false if it is not. If any argument’s value is null, GetSeriesStyle returns null.

See also

GetSeriesStyleOverlayValue

GetSeriesStyleColorValue

Description

Returns the color value associated with a series in a graph in a DataWindow object. You must call GetSeriesStyleColor first to retrieve the color information. (See GetSeriesStyle for information about this method.)

Applies to

DataWindow Web ActiveX DataWindow control

Syntax

\[
\text{Web ActiveX}
\text{number } \text{dwcontrol}.\text{GetSeriesStyleColorValue}() \]

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{dwcontrol}</td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

Return value

Returns an RGB color value.

Usage

To find out the color associated with a series, call GetSeriesStyleColor to retrieve the information, then immediately afterward, call GetSeriesStyleColorValue and examine the return value.
Since data points in a series can have their own style settings, the color setting for a series might not match the color for a specific data point within that series.

See also

GetSeriesStyle

GetSeriesStyleFillPattern

Description

Returns the fill pattern associated with a series in a graph in a DataWindow object. You must call GetSeriesStyleFill first to retrieve the fill information. (See GetSeriesStyle for information about this method.)

Applies to

DataWindow Web ActiveX DataWindow control

Syntax

Web ActiveX

number dwcontrol.GetSeriesStyleFillPattern ( )

Argument | Description
---|---
dwcontrol | A reference to a DataWindow control containing the graph

Return value

Returns an integer representing the fill pattern.

For a list of values and their meanings, see FillPattern on page 480.

Usage

To find out the fill pattern associated with a series, call GetSeriesStyleFill to retrieve the information, then immediately afterward, call GetSeriesStyleFillPattern and examine the return value.

Since data points in a series can have their own style settings, the fill pattern for a series might not match the fill pattern for a specific data point within that series.

See also

GetSeriesStyle

GetSeriesStyleLineStyle

Description

Returns the line style associated with a series in a graph in a DataWindow object. You must call GetSeriesStyleLine first to retrieve the line style information. (See GetSeriesStyle for information about this method.)

Applies to

DataWindow Web ActiveX DataWindow control

Syntax

Web ActiveX

number dwcontrol.GetSeriesStyleLineStyle ( )
CHAPTER 10  Methods for Graphs in the DataWindow Control

GetSeriesStyleLineWidth

Description
Returns the line width associated with a series in a graph in a DataWindow object. You must call GetSeriesStyleLine first to retrieve the line style information. (See GetSeriesStyle for information about this method.)

Applies to
DataWindow Web ActiveX  DataWindow control

Syntax
Web ActiveX

number dwcontrol.GetSeriesStyleLineWidth ( )

Argument Description

dwcontrol  A reference to a DataWindow control containing the graph

Return value
Returns the width of the line in pixels.

Usage
To find out the line width or line style associated with a series, call GetSeriesStyleLine to retrieve the information, then immediately afterward, call GetSeriesStyleLineWidth and GetSeriesStyleLineStyle and examine the return values.

Since data points in a series can have their own style settings, the line width for a series might not match the line width for a specific data point within that series.

See also
GetSeriesStyle
GetDataStyleLineWidth
GetSeriesStyleOverlayValue

Description
Returns a value indicating whether a series is an overlay, that is, whether it is shown on top of another graph type. You must call GetSeriesStyleOverlay first to retrieve the overlay information. (See GetSeriesStyle for information about this method.)

Applies to
DataWindow Web ActiveX  DataWindow control

Syntax
Web ActiveX

boolean dwcontrol.GetSeriesStyleOverlayValue()

Argument Description

dwcontrol  A reference to a DataWindow control containing the graph

Return value
Returns true if the series is an overlay and false if it is not.

Usage
To find out whether a series is an overlay, call GetSeriesStyleOverlay to retrieve the information, then immediately afterward, call GetSeriesStyleOverlayValue and examine the return value.

See also
GetSeriesStyle

GetSeriesStyleSymbolValue

Description
Returns the symbol associated with a series in a graph in a DataWindow object. You must call GetSeriesStyleLine first to retrieve the line style information. (See GetSeriesStyle for information about this method.)

Applies to
DataWindow Web ActiveX  DataWindow control

Syntax
Web ActiveX

number dwcontrol.GetSeriesStyleSymbolValue()

Argument Description

dwcontrol  A reference to a DataWindow control containing the graph

Return value
Returns an integer representing a data point’s symbol.
For a list of values and their meanings, see grSymbolType on page 483.

Usage

To find out the symbol associated with a series, call GetSeriesStyleSymbol to retrieve the information, then immediately afterward, call GetSeriesStyleSymbolValue and examine the return value.

Since data points in a series can have their own style settings, the symbol for a series might not match the symbol for a specific data point within that series.

See also

GetSeriesStyle

GetSeriesTransparency

Description

Obtains the transparency percentage of a series in a DirectX 3D graph (those with 3D rendering).

Applies to

DataWindow control

Syntax

integer dwcontrol.GetSeriesTransparency( string graphcontrol, string series, REF int transparency)

Argument | Description
--- | ---
dwcontrol | A reference to the DataWindow control containing the graph.
graphcontrol | A string whose value is the name of the graph in the DataWindow control.
series | The string that identifies the series from which you want the transparency value.
transparency | Integer value for percent transparency. A value of 0 means that the series is opaque and a value of 100 means that it is completely transparent.

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, GetSeriesTransparency returns null.

Usage

GetSeriesTransparency retrieves data from any DirectX 3D graph (those with 3D rendering).

Examples

These statements obtain the transparency percentage of the series named Costs in the graph gr_computers in the DataWindow control dw_equipment:

```plaintext
integer SeriesNbr, rtn, ser_transp_value

// Get the number of the series.
SeriesNbr = dw_equipment.FindSeries( &
        "gr_computers", "Costs")
```
ObjectAtPointer

Description
Finds out where the user clicked in a graph. `ObjectAtPointer` reports the region of the graph under the pointer and stores the associated series and data point numbers in the designated variables.

Applies to
`PowerBuilder DataWindow` DataWindow control
`DataWindow Web ActiveX` DataWindow control

Syntax
```
PowerBuilder
grObjectType dwcontrol.ObjectAtPointer ( string graphcontrol, REF integer seriesnumber, REF integer datapoint )

Web ActiveX
number dwcontrol.ObjectAtPointer ( string graphcontrol )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td><code>graphcontrol</code></td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td><code>seriesnumber</code></td>
<td>In PowerBuilder, an integer variable in which you want to store the number of the series under the pointer. For the Web ActiveX, call <code>ObjectAtPointerSeries</code> to get the value instead of specifying the reference argument.</td>
</tr>
<tr>
<td><code>datapoint</code></td>
<td>In PowerBuilder, an integer variable in which you want to store the number of the data point under the pointer. For the Web ActiveX, call <code>ObjectAtPointerDataPoint</code> to get the value instead of specifying the reference argument.</td>
</tr>
</tbody>
</table>

Return value
Returns a value of the `grObjectType` enumerated datatype (PowerBuilder) or a number (Web ActiveX) identifying the type of object under the pointer if the user clicks anywhere in the graph (including an empty area) and a null value if the user clicks outside the graph.
For a list of type values, see grObjectType on page 482.

**Usage**

The `ObjectAtPointer` function allows you to find out how the user is interacting with the graph. The function returns a value of the `grObjectType` enumerated datatype identifying the part of the graph. When the user clicks in a series, data point, or category, `ObjectAtPointer` stores the series and/or data point numbers in designated variables.

When the user clicks a data point (or other data mark, such as line or bar), or on the series labels in the legend, `ObjectAtPointer` stores the series number in the designated variable. When the user clicks on a data point or category tickmark label, `ObjectAtPointer` stores the data point number in the designated variable.

When the user clicks in a series, but not on the actual data point, `ObjectAtPointer` stores 0 in `datapoint` and when the user clicks in a category, `ObjectAtPointer` stores 0 in `seriesnumber`. When the user clicks other parts of the graph, `ObjectAtPointer` stores 0 in both variables.

**Examples**

**PowerBuilder**

These statements store the series number and data point number at the pointer location in the graph named `gr_computers` in the DataWindow control `dw_equipment` in `SeriesNbr` and `ItemNbr`:

```powerbuilder
integer SeriesNbr, ItemNbr

dw_equipment.ObjectAtPointer("gr_computers", &
    SeriesNbr, ItemNbr)
```

---

**ObjectAtPointer**

**DataPoint**

Description

Returns the number of the data point under the pointer. You must call `ObjectAtPointer` first to retrieve the pointer position information.

**Applies to**

*DataWindow Web ActiveX*  
DataWindow control

**Syntax**

Web ActiveX

```powerbuilder
number dwcontrol.ObjectAtPointerDataPoint ()
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to a DataWindow control containing the graph</td>
</tr>
</tbody>
</table>

**Return value**

Returns the number of the data point.
ObjectAtPointerSeries

Usage
To find out the data point and series under the pointer, call ObjectAtPointer to retrieve the information, then immediately afterward, call ObjectAtPointerDataPoint and ObjectAtPointerSeries and examine the return values.

See also
ObjectAtPointer
ObjectAtPointerSeries

ObjectAtPointerSeries

Description
Returns the number of the series under the pointer. You must call ObjectAtPointer first to retrieve the pointer position information.

Applies to
DataWindow Web ActiveX DataWindow control

Syntax
Web ActiveX

number dwcontrol.ObjectAtPointerSeries ( )

Argument Description

dwcontrol A reference to a DataWindow control containing the graph

Return value
Returns the number of the series.

Usage
To find out the data point and series under the pointer, call ObjectAtPointer to retrieve the information, then immediately afterward, call ObjectAtPointerDataPoint and ObjectAtPointerSeries and examine the return values.

See also
ObjectAtPointer
ObjectAtPointerDataPoint

Reset

Description
Deletes the data, the categories, or the series from a graph.

Reset is for graphs within a DataWindow object with an external data source. It does not apply to other graphs in DataWindow objects because their data comes directly from the DataWindow.

Applies to
PowerBuilder DataWindow DataWindow control
DataWindow Web ActiveX DataWindow control
CHAPTER 10    Methods for Graphs in the DataWindow Control

Syntax

**PowerBuilder**

```powerbuilder
type dwcontrol.Reset ( grResetType graphresettype )
```

**Web ActiveX**

```webactivex
type dwcontrol.Reset ( number graphresettype )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
</tbody>
</table>
| `graphresettype` | A value of the grResetType enumerated datatype specifying whether you want to delete only data values or all series and all data values:  
|                  | • All! – Delete all series, categories, and data in `dwcontrol`.            |
|                  | • Category! – Delete categories and data in `dwcontrol`.                    |
|                  | • Data! – Delete data in `dwcontrol`.                                       |
|                  | • Series! – Delete the series and data in `dwcontrol`.                      |

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, `Reset` returns null. The return value is usually not used.

Usage

Use `Reset` to clear the data in a graph before you add new data.

Examples

**PowerBuilder**

This statement deletes the series and data, but leaves the categories, in the graph `gr_product_data` in the DataWindow `dw_prod`. The DataWindow object has an external data source:

```powerbuilder
dw_prod.Reset("gr_product_data", Series!)
```

---

**ResetDataColors**

Description

Restores the color of a data point to the default color for its series.

Applies to

* **PowerBuilder DataWindow** DataWindow control  
* **DataWindow Web ActiveX** DataWindow control

Syntax

**PowerBuilder**

```powerbuilder
type dwcontrol.ResetDataColors ( string graphcontrol, integer seriesnumber, long datapointnumber )
```

**Web ActiveX**

```webactivex
type dwcontrol.ResetDataColors ( string graphcontrol, number seriesnumber, number datapointnumber )
```
SaveAs

**Argument** | **Description**
---|---
dwcontrol | A reference to the DataWindow control containing the graph

**graphcontrol** | A string whose value is the name of the graph in the DataWindow control

**seriesnumber** | The number of the series in which you want to reset the color of a data point

**datapointnumber** | The number of the data point for which you want to reset the color

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, ResetDataColors returns null.

**Default color for data points**
To set the color for a series, use SetSeriesStyle. The color you set for the series is the default color for all data points in the series.

**Examples**

**PowerBuilder** These statements change the color of data point 10 in the series named Costs in the graph gr_computers in the DataWindow control dw_equipment to the color for the series:

```powerbuilder
SeriesNbr = dw_equipment.FindSeries("gr_computers", & "Costs")
dw_equipment.ResetDataColors("gr_computers", & SeriesNbr, 10)
```

**See also**
GetDataStyle
GetSeriesStyle
SetDataStyle
SetSeriesStyle

**SaveAs**

**Description**
Saves the data in a graph in the format you specify.

**Applies to**
*PowerBuilder DataWindow* DataWindow control

**Syntax**

```powerbuilder
integer dwcontrol.SaveAs ( string graphcontrol, string filename, SaveAsType saveastype, boolean colheading, boolean encoding )
```

962  

**PowerBuilder**
CHAPTER 10  Methods for Graphs in the DataWindow Control

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, `SaveAs` returns null.

If you do not specify any arguments, PowerBuilder saves the DataWindow data rather than the data in the graph control. In this case, or in the case where you specify only the graph control name as an argument, PowerBuilder displays the Save As dialog box, letting the user specify the format of the saved data.

The Web ActiveX is a safely scriptable control and does not take actions that can affect the client’s environment. Therefore, it does not support `SaveAs`.

Examples

**PowerBuilder**  This statement saves the contents of `gr_computers` in the DataWindow control `dw_equipment` to the file `G:\INVENTORY\SALES.XLS`. The format is comma-separated values with column headings:

```powerbuilder
dw_equipment.SaveAs("gr_computers", &
    "G:\INVENTORY\SALES.XLS", CSV!, true)
```

Print

SaveAs

ARGUMENTS

**Argument**  **Description**

dwcontrol  A reference to the DataWindow control containing the graph.

graphcontrol  A string whose value is the name of the graph in the DataWindow control.

filename  (optional)  A string whose value is the name of the file in which you want to save the data in the graph. If you omit `filename` or specify an empty string (""), the user is prompted for a file name.

saveastype  (optional)  A value of the `SaveAsType` enumerated datatype (in PowerBuilder) or an integer (for the Web ActiveX) specifying the format in which to save the data represented in the graph.

For a list of values, see `SaveAsType` on page 486.

colheading  (optional)  A boolean value indicating whether you want column headings with the saved data. The default value is true. This argument is used for the following formats: `Clipboard`, `CSV`, `Excel`, and `Text`. For most other formats, column headings are always saved.

encoding  (optional)  Character encoding of the file to which the data is saved. This parameter applies only to the following formats: `TEXT`, `CSV`, `SQL`, `HTML`, and `DIF`. If you do not specify an `encoding` parameter, the file is saved in ANSI format. Values are:

- EncodingANSI! (default)
- EncodingUTF8!
- EncodingUTF16LE!
- EncodingUTF16BE!
SeriesCount

Description
Counts the number of series in a graph.

Applies to
- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**  DataWindow control

Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.SeriesCount ( string graphcontrol )
```

**Web ActiveX**

```powerbuilder
number dwcontrol.SeriesCount ( string graphcontrol )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control</td>
</tr>
</tbody>
</table>

Return value
Returns the number of series in the graph if it succeeds and -1 if an error occurs. If any argument’s value is null, SeriesCount returns null.

Examples

**PowerBuilder**  These statements store in the variable li_series_count the number of series in the graph gr_computers in the DataWindow control dw_equipment:

```powerbuilder
integer li_series_count
li_series_count = &dw_equipment.SeriesCount("gr_computers")
```

See also
CategoryCount
DataCount

SeriesName

Description
Obtains the series name associated with the specified series number.

Applies to
- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**  DataWindow control

Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.SeriesName ( string graphcontrol, integer seriesnumber )
```

**Web ActiveX**
### Methods for Graphs in the DataWindow Control

#### dwcontrol.SeriesName

**Description**

A reference to the DataWindow control containing the graph.

**Argument**

- `dwcontrol`: A reference to the DataWindow control containing the graph.
- `graphcontrol`: A string whose value is the name of the graph in the DataWindow control.
- `seriesnumber`: The number of the series for which you want to obtain the name.

**Return value**

Returns the name assigned to the series. If an error occurs, it returns the empty string (""). If any argument’s value is null, SeriesName returns null.

**Usage**

Series are numbered consecutively, from 1 to the value returned by `SeriesCount`. When you delete a series, the series are renumbered to keep the numbering consecutive. You can use SeriesName to find out the name of the series associated with a series number.

**Examples**

**PowerBuilder**

These statements store in the variable `ls_SeriesName` the name of series 5 in the graph `gr_computers` in the DataWindow control `dw_equipment`:

```powershell
string ls_SeriesName
ls_SeriesName = &
   dw_equipment.SeriesName("gr_computers", 5)
```

**See also**

CategoryName
GetData

### SetDataLabelling

**Description**

Set the data label for a DirectX 3D graph.

**Applies to**

DataWindow control

**Syntax**

```powershell
integer dwcontrol.SetDataLabelling (string graphcontrol, int seriesnumber, int datapoint, boolean value)
```

**Argument**

- `dwcontrol`: A reference to the DataWindow control containing the graph.
- `graphcontrol`: A string whose value is the name of the graph in the DataWindow control.
- `seriesnumber`: The number that identifies the series in which you want to set the data labelling value.
- `datapoint`: An integer.
- `value`: A boolean.

**Examples**

These statements set the data label for series 5 in the graph `gr_computers` in the DataWindow control `dw_equipment`:

```powershell
int datapoint = 0;
int value = true;
dw_equipment.SetDataLabelling("gr_computers", 5, datapoint, value);
```
SetDataPieExplode

**Description**
Explodes a pie slice in a pie graph. The exploded slice is moved away from the center of the pie, which draws attention to the data. You can explode any number of slices of the pie.

**Applies to**
- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**  DataWindow control

**Syntax**
```powerbuilder
define_function
dwcontrol.SetDataPieExplode ( string graphcontrol, integer seriesnumber, integer datapoint, integer percentage )
```

**Argument | Description**
--- | ---
datapoint | The datapoint.
value | Indicates whether to label the data with its value.

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, `SetDataLabelling` returns null.

**Usage**
`SetDataLabelling` is used to indicate whether or not to label the data with the numbers for data in DirectX 3D Area, Bar, Col, or Line graphs. You cannot use this method with DirectX 3D Pie graphs.

**Examples**
These statements obtain the series and datapoint for the graph `gr_1` in the `DataWindow` control `dw_employee`.

```powerbuilder
ingoal SeriesNbr, ItemNbr
grobjecttype clickedtype

// Get the number of the series and datapoint
clickedtype = this.objectatpointer("gr_1", &
    SeriesNbr, ItemNbr)

// Set data label
dw_employee.SetDataLabelling("gr_1", &
    SeriesNbr, ItemNbr, true)
```

**See also**
- `GetDataLabelling`
- `GetSeriesLabelling`
- `SetSeriesLabelling`
Web ActiveX

number dwcontrol.SetDataPieExplode (string graphcontrol, number seriesnumber, number datapoint, number percentage)

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number that identifies the series.</td>
</tr>
<tr>
<td>datapoint</td>
<td>The number of the data point (that is, the pie slice) to be exploded.</td>
</tr>
<tr>
<td>percentage</td>
<td>A number between 0 and 100 that is the percentage of the radius that the pie slice is moved away from the center. When percentage is 100, the tip of the slice is even with the circumference of the pie’s circle.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetDataPieExplode returns null.

Usage

If the graph is not a pie graph, SetDataPieExplode has no effect.

Examples

**PowerBuilder**  This example explodes the pie slice under the pointer to 50% when the user double-clicks within the graph. The code checks the property GraphType to make sure the graph is a pie graph. It then finds out whether the user clicked on a pie slice by checking the series and data point values set by ObjectAtPointer. The script is for the DoubleClicked event of the DataWindow control:

```powerbuilder
integer series, datapoint
grobjecttype clickedtype
integer percentage

percentage = 50
IF (This.GraphType <> PieGraph! AND &
This.GraphType <> Pie3D!) THEN RETURN

clickedtype = This.ObjectAtPointer ("gr_equipment", &
series, datapoint)

IF (series > 0 and datapoint > 0) THEN
This.SetDataPieExplode("gr_equipment", series, &
datapoint, percentage)

END IF
```

See also

GetDataPieExplode
SetDataStyle

Specifies the appearance of a data point in a graph. The data point’s series has appearance settings that you can override with SetDataStyle.

<table>
<thead>
<tr>
<th>To</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set the data point’s colors</td>
<td>Syntax 1</td>
</tr>
<tr>
<td>For the Web ActiveX, called SetDataStyleColor</td>
<td></td>
</tr>
<tr>
<td>Set the line style and width for the data point</td>
<td>Syntax 2</td>
</tr>
<tr>
<td>For the Web ActiveX, called SetDataStyleLine</td>
<td></td>
</tr>
<tr>
<td>Set the fill pattern for the data point</td>
<td>Syntax 3</td>
</tr>
<tr>
<td>For the Web ActiveX, called SetDataStyleFill</td>
<td></td>
</tr>
<tr>
<td>Set the symbol for the data point</td>
<td>Syntax 4</td>
</tr>
<tr>
<td>For the Web ActiveX, called SetDataStyleSymbol</td>
<td></td>
</tr>
</tbody>
</table>

### Syntax 1

**For setting a data point’s colors**

Specifies the colors of a data point in a graph.

**Description**

Sets the data point’s colors for a graph in a DataWindow control.

** Applies to **

- PowerBuilder DataWindow Web ActiveX DataWindow control
- DataWindow Web ActiveX DataWindow control

**Syntax**

**PowerBuilder**

- integer `dwcontrol.SetDataStyle` (string `graphcontrol`, integer `seriesnumber`, integer `datapointnumber`, grColorType `colortype`, long `color`)

**Web ActiveX**

- number `dwcontrol.SetDataStyleColor` (string `graphcontrol`, number `seriesnumber`, number `datapointnumber`, number `colortype`, number `color`)

**Argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dwcontrol</code></td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td><code>graphcontrol</code></td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td><code>seriesnumber</code></td>
<td>The number of the series in which you want to set the color of a data point.</td>
</tr>
<tr>
<td><code>datapointnumber</code></td>
<td>The number of the data point for which you want to set the color.</td>
</tr>
<tr>
<td><code>colortype</code></td>
<td>The color type of the data point.</td>
</tr>
<tr>
<td><code>color</code></td>
<td>The color value for the data point.</td>
</tr>
</tbody>
</table>
### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>colortype</code></td>
<td>A value of the grColorType enumerated datatype (in PowerBuilder) or an integer (for the Web ActiveX) specifying the aspect of the data point for which you want to set the color. For a list of values, see grColorType on page 481.</td>
</tr>
<tr>
<td><code>color</code></td>
<td>A long whose value is the new color for <code>colortype</code>.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, `SetDataStyle` returns null.

**Usage**

To change the appearance of a series, use `SetSeriesStyle`. The settings you make for the series are the defaults for all data points in the series.

To reset the color of individual points back to the series color, call `ResetDataColors`.

You can specify the appearance of a data point in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for `pbm_dwngraphcreate` and call `SetDataStyle` in the script for that event. The event `pbm_dwngraphcreate` is triggered just before a graph is created in a DataWindow object.
- **Web ActiveX** Call any of the `SetDataStyle` methods in code for the `onGraphCreate` event.

#### Using `SetDataStyle` with DirectX 3D Graphs

You can only set the color for the foreground. Background, line color, and shade are not supported.

#### Examples

**PowerBuilder** These statements set the text (foreground) color to black for data point 6 in the series named `Salary` in the graph `gr_depts` in the DataWindow control `dw_employees`:

```powerbuilder
integer SeriesNbr

// Get the number of the series
SeriesNbr = &
    dw_employees.FindSeries("gr_depts" , "Salary")

// Set the background color
dw_employees.SetDataStyle("gr_depts" , SeriesNbr, &
    6, Background!, 0)
```

**See also**

- `GetDataStyle`
- `GetSeriesStyle`
SetDataStyle

ResetDataColors
SetSeriesStyle

## Syntax 2

### For the line associated with a data point

Specifies the style and width of a data point’s line in a graph.

### Applies to

- **PowerBuilder DataWindow** DataWindow control
- **DataWindow Web ActiveX** DataWindow control

### Syntax

**PowerBuilder**

```powerbuilder
integer dwcontrol.SetDataStyle ( string graphcontrol, integer seriesnumber, integer datapointnumber, LineStyle linestyle, { integer linewidth } )
```

**Web ActiveX**

```javascript
number dwcontrol.SetDataStyle ( string graphcontrol, number seriesnumber, number datapointnumber, number linestyle, number linewidth )
```

### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number of the series in which you want to set the line style and width of a data point.</td>
</tr>
<tr>
<td>datapointnumber</td>
<td>The number of the data point for which you want to set the line style and width.</td>
</tr>
<tr>
<td>linestyle</td>
<td>A value of the LineStyle enumerated datatype (in PowerBuilder) or an integer (for the Web ActiveX) specifying a line style pattern of dots, dashes, and solid lines. For a list of line style values, see LineStyle on page 484.</td>
</tr>
<tr>
<td>linewidth (optional for PowerBuilder)</td>
<td>An integer whose value is the width of the line in pixels.</td>
</tr>
</tbody>
</table>

### Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetDataStyle returns null.

### Usage

To change the appearance of a series, use SetSeriesStyle. The settings you make for the series are the defaults for all data points in the series.

You can specify the appearance of a data point in the graph before the application draws the graph. To do so:
CHAPTER 10  Methods for Graphs in the DataWindow Control

- **PowerBuilder**  Define a user event for pbm_dwngraphcreate and call SetDataStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX**  Call any of the SetDataStyle methods in code for the onGraphCreate event.

**Examples**

**PowerBuilder**  This example checks the line style used for data point 10 in the series named Costs in the graph gr_computers in the DataWindow control dw_equipment. If it is dash-dot, the SetDataStyle sets it to continuous. The line width stays the same:

```powerbuilder
integer SeriesNbr, line_width
LineStyle line_style

// Get the number of the series
SeriesNbr = dw_equipment.FindSeries( &
   "gr_computers", "Costs")

// Get the current line style
dw_equipment.GetDataStyle("gr_computers", &
   SeriesNbr, 10, line_style, line_width)

// If the pattern is dash-dot, change to continuous
IF line_style = DashDot! THEN &
   dw_equipment.SetDataStyle("gr_computers", &
      SeriesNbr, 10, Continuous!, line_width)
```

**See also**

- GetDataStyle
- GetSeriesStyle
- SetSeriesStyle

**Syntax 3**  For the fill pattern of a data point

**Description**  Specifies the fill pattern for a data point in a graph.

**Applies to**

- **PowerBuilder DataWindow**  DataWindow control
- **DataWindow Web ActiveX**  DataWindow control

**Syntax**

**PowerBuilder**

```powerbuilder
integer dwcontrol.SetDataStyle ( string graphcontrol, integer seriesnumber, integer datapointnumber, FillPattern fillvalue )
```

**Web ActiveX**

```powerbuilder
number dwcontrol.SetDataStyleFill ( string graphcontrol, number seriesnumber, number datapointnumber, number fillvalue )
```
**SetDataStyle**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesnumber</td>
<td>The number of the series in which you want to set the appearance of a data point.</td>
</tr>
<tr>
<td>datapointnumber</td>
<td>The number of the data point for which you want to set the appearance.</td>
</tr>
<tr>
<td>fillvalue</td>
<td>A value of the FillPattern enumerated datatype (in PowerBuilder) or an integer (for the Web ActiveX) specifying the fill pattern for the data point. For a list of values, see FillPattern on page 480.</td>
</tr>
</tbody>
</table>

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetDataStyle returns null.

**Usage**
To change the appearance of a series, use SetSeriesStyle. The settings you make for the series are the defaults for all data points in the series.

You can specify the appearance of a data point in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for pbm_dwngraphcreate and call SetDataStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.
- **Web ActiveX** Call any of the SetDataStyle methods in code for the onGraphCreate event.

**Using SetDataStyle with DirectX 3D Graphs**
You cannot use a fill pattern for a data point.

**See also**
GetDataStyle  
GetSeriesStyle  
SetSeriesStyle

**Syntax 4**
**For the symbol of a data point**

**Description**
Specifies the symbol for a data point in a graph.

**Applies to**

- **PowerBuilder DataWindow** DataWindow control
- **DataWindow Web ActiveX** DataWindow control
Syntax

**PowerBuilder**

```
integer dwcontrol.SetDataStyle ( string graphcontrol, integer seriesnumber, integer datapointnumber, grSymbolType symbolvalue )
```

**Web ActiveX**

```
number dwcontrol.SetDataStyleSymbol ( string graphcontrol, number seriesnumber, number datapointnumber, number symbolvalue )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>seriesnumber</td>
<td>The number of the series in which you want to set the appearance of a data point.</td>
</tr>
<tr>
<td>datapointnumber</td>
<td>The number of the data point for which you want to set the appearance.</td>
</tr>
<tr>
<td>symbolvalue</td>
<td>A value of the grSymbolType enumerated datatype (in PowerBuilder) or an integer (for the Web ActiveX) specifying the symbol for the data point. For a list of values, see grSymbolType on page 483.</td>
</tr>
</tbody>
</table>

**Return value**

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetDataStyle returns null.

**Usage**

To change the appearance of a series, use SetSeriesStyle. The settings you make for the series are the defaults for all data points in the series.

You can specify the appearance of a data point in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for pbm_dwngraphcreate and call SetDataStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX** Call any of the SetDataStyle methods in code for the onGraphCreate event.

**Using SetDataStyle with DirectX 3D Graphs**

You cannot specify specific symbols for the data point.

**See also**

GetDataStyle
GetSeriesStyle
SetSeriesStyle
SetDataTransparency

Description
Sets the transparency percentage for a data point in a series in a DirectX 3D graph.

Applies to
DataWindow control

Syntax
integer dwcontrol.SetDataTransparency ( string graphcontrol, integer seriesnumber, int datapoint, int transparency)

Return value
Returns 1 if it succeeds and -1 if an error occurs. If any argument's value is null, SetDataTransparency returns null.

Usage
SetDataTransparency sets the transparency value of a data point in any DirectX 3D graph (those with 3D rendering).

Examples
These statements set the transparency percentage to 50% for data point 3 in the series named Costs in the graph gr_1 in the DataWindow control dw_employee:

```powerbuilder
type integer SeriesNbr, ItemNbr, TransNbr
grObjectType clickedtype

// Get the number of the series and datapoint clickedtype = this.ObjectAtPointer("gr_1", & SeriesNbr, ItemNbr)

// The following statement sets Transparency to 50%
TransNbr = 50

dw_employee.SetDataTransparency("gr_1", & SeriesNbr, ItemNbr, TransNbr)
```

See also
FindSeries
GetDataTransparency
GetSeriesTransparency
SetSeriesTransparency
**SetSeriesLabelling**

**Description**
Set the series label for a DirectX 3D graph.

**Applies to**
DataWindow control

**Syntax**
```plaintext
integer dwcontrol.SetSeriesLabelling (string graphcontrol, string series, boolean value)
```

**Argument** | **Description**
--- | ---
`dwcontrol` | A reference to the DataWindow control containing the graph.
`graphcontrol` | A string whose value is the name of the graph in the DataWindow control.
`series` | The string that names the series in which you want to change the series label setting.
`value` | Indicates whether to label the series with its values.

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetSeriesLabelling returns null.

**Usage**
SetDataLabelling is used to indicate whether or not to label the series with the data numbers for data in DirectX 3D Area, Bar, Col, or Line graphs. You cannot use this method with DirectX 3D Pie graphs.

**Examples**
These statements obtain the series and datapoint of graph `gr_1` and the DataWindow control `dw_employee`.

```plaintext
integer SeriesNbr, ItemNbr
string ls_SeriesName
grObjectType clickedtype

// Get the number of the series and datapoint
clickedtype = this.ObjectAtPointer("gr_1", & SeriesNbr, ItemNbr)

// Get the name of series
ls_SeriesName = dw_employee-SeriesName("gr_1", & SeriesNbr)

// Set Series label
dw_employee.SetSeriesLabelling("gr_1", & ls_SeriesName, true)
```

**See also**

</tbody>
</table>

Syntax 1

For setting a series’ colors

Description
Specifies the colors of a series in a graph.

Applies to

*PowerBuilder DataWindow*  DataWindow control
*DataWindow Web ActiveX*  DataWindow control

Syntax

**PowerBuilder**

```pascal
integer dwcontrol.SetSeriesStyle ( string graphcontrol, string seriesname, grColorType colortype, long color )
```

**Web ActiveX**

```pascal
number dwcontrol.SetSeriesStyleColor ( string graphcontrol, string seriesname, number colortype, number color )
```

<td>A string whose value is the name of the series for which you want to set the color.</td>
</tr>
</tbody>
</table>
Chapter 10  Methods for Graphs in the DataWindow Control

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetSeriesStyle returns null.

Usage

Data points in a series can have their own style settings. Settings made with SetDataStyle set the style of individual data points and override series settings.

The graph stores style information for properties that do not apply to the current graph type. For example, you can set the fill pattern in a two-dimensional line graph or the line style in a bar graph, but that fill pattern or line style will not be visible.

You can specify the appearance of a series in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for pbm_dwngraphcreate and call SetSeriesStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX** Call any of the SetSeriesStyle methods in the onGraphCreate event.

Using SetSeriesStyle with DirectX 3D Graphs

You can only set the color for the foreground. Background, line color, and shade are not supported.

Examples

**PowerBuilder** This statement sets the background color of the series named Salary in the graph gr_depts in the DataWindow control dw_employees to black:

```powershell
dw_employees.SetSeriesStyle("gr_depts", & "Salary", Background!, 0)
```

These statements in the Clicked event of the graph control gr_product_data coordinate line color between it and the graph gr_sales_data. The script stores the line color for the series under the mouse pointer in the graph gr_product_data in the variable line_color. Then it sets the line color for the series Northeast in the graph gr_sales_data within the DataWindow control dw_sales to that color:

```powershell
string SeriesName
```
SetSeriesStyle

integer SeriesNbr, Series_Point
long line_color
grObjectType MouseHit
MouseHit = This.ObjectAtPointer( &
    SeriesNbr, Series_Point)

IF MouseHit = TypeSeries! THEN
    SeriesName = &
        gr_product_data.SeriesName(SeriesNbr)

        gr_product_data.GetSeriesStyle(SeriesName, &
            LineColor!, line_color)

dw_sales.SetSeriesStyle("gr_sales_data", &
    "Northeast", LineColor!, line_color)
END IF

Syntax 2  For lines in a graph
Description Specifies the style and width of a series’ lines in a graph.
Applies to
    PowerBuilder DataWindow  DataWindow control
    DataWindow Web ActiveX  DataWindow control

Syntax
PowerBuilder
    integer dwcontrol.SetSeriesStyle ( string graphcontrol, string
        seriesname, LineStyle linestyle {, integer linewidth } )

Web ActiveX
    number dwcontrol.SetSeriesStyleLine ( string graphcontrol, string
        seriesname, number linestyle, number linewidth )

</table>
CHAPTER 10  Methods for Graphs in the DataWindow Control

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetSeriesStyle returns null.

Usage

Data points in a series can have their own style settings. Settings made with SetDataStyle set the style of individual data points and override series settings.

The graph stores style information for properties that do not apply to the current graph type. For example, you can set the fill pattern in a two-dimensional line graph or the line style in a bar graph, but that fill pattern or line style will not be visible.

You can specify the appearance of a series in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for pbm_dwngraphcreate and call SetSeriesStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX** Call any of the SetSeriesStyle methods in the onGraphCreate event.

Examples

**PowerBuilder** This statement sets the line style and width for the series named Costs in the graph gr_product_data in the DataWindow dw_prod:

```powershell
dw_prod.SetSeriesStyle("gr_product_data", "Costs", & Dot!, 5)
```

<tr>
<td>seriesname</td>
<td>A string whose value is the name of the series in which you want to set the appearance.</td>
</tr>
<tr>
<td>fillvalue</td>
<td>A value of the FillPattern enumerated datatype (PowerBuilder) or an integer (Web ActiveX) specifying the fill pattern for the series. For a list of values, see FillPattern on page 480.</td>
</tr>
</tbody>
</table>

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetSeriesStyle returns null.

Usage

Data points in a series can have their own style settings. Settings made with SetDataStyle set the style of individual data points and override series settings.

The graph stores style information for properties that do not apply to the current graph type. For example, you can set the fill pattern in a two-dimensional line graph or the line style in a bar graph, but that fill pattern or line style will not be visible.

You can specify the appearance of a series in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for pbm_dwngraphcreate and call SetSeriesStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX** Call any of the SetSeriesStyle methods in the onGraphCreate event.

Using SetSeriesStyle with DirectX 3D Graphs

You cannot use a fill pattern for a series.
Examples

**PowerBuilder**  This statement sets the fill pattern used for the series named Costs in the graph gr_computers in the DataWindow control dw_equipment to Horizontal:

   dw_equipment.SetSeriesStyle("gr_computers", "Costs", Horizontal!)

Syntax 4  For the symbols in a graph

Description  Specifies the symbol for data markers in a series.

Applies to  

| PowerBuilder DataWindow | DataWindow control |
| Web ActiveX | DataWindow control |

Syntax

**PowerBuilder**

```powershell
integer dwcontrol.SetSeriesStyle ( string graphcontrol, string seriesname, grSymbolType symbolvalue )
```

**Web ActiveX**

```powershell
number dwcontrol.SetSeriesStyleSymbol ( string graphcontrol, string seriesname, number symbolvalue )
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>seriesname</td>
<td>A string whose value is the name of the series in which you want to set the appearance.</td>
</tr>
<tr>
<td>symbolvalue</td>
<td>A value of the grSymbolType enumerated datatype (PowerBuilder) or an integer (Web ActiveX) specifying the symbol for the series.</td>
</tr>
</tbody>
</table>

For a list of values, see grSymbolType on page 483.

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetSeriesStyle returns null.

Usage

Data points in a series can have their own style settings. Settings made with SetDataStyle set the style of individual data points and override series settings.
The graph stores style information for properties that do not apply to the current graph type. For example, you can set the fill pattern in a two-dimensional line graph or the line style in a bar graph, but that fill pattern or line style will not be visible.

You can specify the appearance of a series in the graph before the application draws the graph. To do so:

- **PowerBuilder** Define a user event for pbm_dwngraphcreate and call SetSeriesStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX** Call any of the SetSeriesStyle methods in the onGraphCreate event.

**Using SetSeriesStyle with DirectX 3D Graphs**
You cannot specify specific symbols for the data markers in a series.

**Examples**

**PowerBuilder** This statement sets the symbol for the series named Costs in the graph gr_computers in the DataWindow control dw_equipment to X:

```powerbuilder
dw_equipment.SetSeriesStyle("gr_computers", &"Costs", SymbolX)
```

**See also**

GetDataStyle
GetSeriesStyle
SetDataStyle

**Syntax 5**

**For creating an overlay in a graph**

**Description**
Specifies whether a series is an overlay, meaning that the series is represented by a line on top of another graph type.

** Applies to **

- **PowerBuilder** DataWindow DataWindow control
- **DataWindow** Web ActiveX DataWindow control

**Syntax**

**PowerBuilder**

```powerbuilder
integer dwcontrol.SetSeriesStyle ( string graphcontrol, string series, boolean overlaystyle )
```

**Web ActiveX**

```powerbuilder
number dwcontrol.SetSeriesStyleOverlay ( string graphcontrol, string series, boolean overlaystyle )
```
CHAPTER 10  Methods for Graphs in the DataWindow Control

Return value

Returns 1 if it succeeds and -1 if an error occurs. If any argument's value is null, SetSeriesStyle returns null.

Usage

You can specify the appearance of a series in the graph before the application draws the graph. To do so:

- **PowerBuilder**  Define a user event for pbm_dwngraphcreate and call SetSeriesStyle in the script for that event. The event pbm_dwngraphcreate is triggered just before a graph is created in a DataWindow object.

- **Web ActiveX**  Call any of the SetSeriesStyle methods in the onGraphCreate event.

Using SetSeriesStyle with DirectX 3D Graphs

You cannot use the overlay style for a series.

Examples

**PowerBuilder**  These statements in the Clicked event of the DataWindow control dw_employees store the style of the series under the pointer in the graph gr_depts in the variable style_type. If the style of the series is overlay (true), the script changes the style to normal (false):

```powerbuilder
string SeriesName
integer SeriesNbr, Data_Point
boolean overlay_style
grObjectType MouseHit

MouseHit = dw_employees.ObjectAtPointer( "gr_depts", SeriesNbr, Data_Point)

IF MouseHit = TypeSeries! THEN
    SeriesName = &
    dw_employees.SeriesName("gr_depts",SeriesNbr)
```

**Argument** | **Description**
--- | ---
dwcontrol | A reference to the DataWindow control containing the graph.
graphcontrol | A string whose value is the name of the graph in the DataWindow control.
series | A string (PowerBuilder) or integer (Web ActiveX) whose value is the name of the series whose overlay status you want to change.
overlaystyle | A boolean value indicating whether you want the series to be an overlay, meaning that the series is shown in front as a line. Set overlaystyle to true to make the specified series an overlay. Set it to false to remove the overlay setting.
SetSeriesTransparency

```
dw_employees.GetSeriesStyle("gr_depts", &SeriesName, overlay_style)
IF overlay_style THEN &
    dw_employees.SetSeriesStyle("gr_depts", &SeriesName, false)
END IF
```

See also
- GetDataStyle
- GetSeriesStyle
- SetDataStyle

**SetSeriesTransparency**

**Description**
Sets the transparency percentage of a series in a DirectX 3D type graph.

**Applies to**
DataWindow control

**Syntax**
```
integer dwcontrol.SetSeriesTransparency ( string graphcontrol, stringseries, int transparency)
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dwcontrol</td>
<td>A reference to the DataWindow control containing the graph.</td>
</tr>
<tr>
<td>graphcontrol</td>
<td>A string whose value is the name of the graph in the DataWindow control.</td>
</tr>
<tr>
<td>series</td>
<td>The string that identifies the series in which you want to set the transparency value.</td>
</tr>
<tr>
<td>transparency</td>
<td>Integer value for percentage transparency. A value of 0 means that the series is opaque and a value of 100 means that it is completely transparent.</td>
</tr>
</tbody>
</table>

**Return value**
Returns 1 if it succeeds and -1 if an error occurs. If any argument’s value is null, SetSeriesTransparency returns null.

**Usage**
SetSeriesTransparency sets the transparency value for a series in a DirectX 3D graph (those with 3D rendering).

**Examples**
These statements set the transparency percentage to 50% for the series named Costs in the graph gr_1 in the DataWindow control dw_employee:

```
integer SeriesNbr, ItemNbr, TransNbr
string ls_SeriesName
grObjectType clickedtype

// Get the number of the series and datapoint
```
clickedtype = this.ObjectAtPointer("gr_1", &
    SeriesNbr, ItemNbr)

    //Get the name of series
ls_SeriesName = dw_employee.SeriesName("gr_1", &
    SeriesNbr)

    //The following statement sets Transparency to 50%
TransNbr = 50

dw_employee.SetSeriesTransparency("gr_1", &
    ls_SeriesName, TransNbr)

CHAPTER 11

Transaction Object Control for Web ActiveX

About this chapter

This chapter provides reference information for the Transaction Object control, which is used with the Sybase DataWindow Web control for ActiveX (Web ActiveX) to provide transaction management and database connections that can be shared by more than one Web ActiveX control.

Contents

<table>
<thead>
<tr>
<th>Topic</th>

</tr>
</tbody>
</table>

Using a transaction object with the Web ActiveX

When to use a separate transaction object

Both the Web ActiveX and the Transaction Object control can establish a database connection. The one you use depends on your needs.

There are two main reasons to use the Transaction Object control:

- You can make one database connection for several Web ActiveX controls, saving the overhead of multiple connections.
- You can control transaction processing with Connect and Disconnect methods, equivalent to the SQL statements CONNECT and DISCONNECT. If the AutoCommit property is set to false, you can control when an update is committed or rolled back with Commit and Rollback methods.

If you have only one control and are simply retrieving data, you do not need either of these features. Instead of instantiating a separate control, you can set the connection properties of the Web ActiveX itself and allow it to connect and disconnect for each database access.
Properties of the Transaction Object control

Instantiating a transaction object

To use a transaction object with the Web ActiveX, you add an OBJECT element to the Web page. You can provide the connection information in HTML PARAM elements or in JavaScript statements.

The HTML to instantiate a transaction object looks like this:

```html
<OBJECT id=trans1 height=27 name=trans1 classid="...
width=36>
  <PARAM VALUE=dba NAME=LogID></PARAM>
  <PARAM VALUE=sql NAME=LogPass></PARAM>
  <PARAM VALUE="Driver=com.sybase.jdbc3.jdbc.SybDriver,
    URL=jdbc:sybase:Tds:localhost:7373"
    NAME=dbParm></PARAM>
  <PARAM VALUE="" NAME=Lock></PARAM>
  <PARAM VALUE=0 NAME=AutoCommit></PARAM>
</OBJECT>
```

To connect to the DBMS and associate the transaction object with a Web ActiveX, you would write JavaScript like this:

```javascript
trans1.Connect();
if (trans1.GetSQLCode() == 0) {
    dw1.SetTransObject(trans1);
}
```

For more information about using the Web ActiveX and Transaction Object control, see the DataWindow Programmers Guide.

Properties of the Transaction Object control

Transaction Object properties provide the information necessary to connect to a particular database.

In a Web page, you specify values for ActiveX properties using the HTML PARAM element.

```html
<PARAM VALUE=value NAME="propertyname"></PARAM>
```
Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoCommit</td>
<td>Number. The automatic commit indicator. Values are:</td>
</tr>
<tr>
<td></td>
<td>• 0 – Do not commit automatically after every database activity.</td>
</tr>
<tr>
<td></td>
<td>• 1 – Commit automatically after every database activity.</td>
</tr>
<tr>
<td>dbParm</td>
<td>String. JDBC connection information. The typical connection string includes values for Driver and URL. For example, this connection string uses the Sybase JConnect driver and connects to SQL Anywhere running on the local machine (localhost):</td>
</tr>
<tr>
<td>Lock</td>
<td>String. The isolation level.</td>
</tr>
<tr>
<td></td>
<td>For information on appropriate values for JDBC, see Connecting to Your Database.</td>
</tr>
<tr>
<td>LogId</td>
<td>String. The name or ID of the user who will be logging on to the server.</td>
</tr>
<tr>
<td>LogPassword</td>
<td>String. The password that will be used to log in to the server.</td>
</tr>
</tbody>
</table>

Methods of the Transaction Object control

These methods provide functionality that is provided by SQL statements and transaction object properties in PowerBuilder.

AboutBox

Description Displays information about the DataWindow transaction object.
Applies to Web ActiveX Transaction Object control
Syntax void transaction.AboutBox() 
Return value None
Commit

Description
Commits all database changes since the last commit.

Applies to
Web ActiveX Transaction Object control

Syntax
void transaction.Commit( )

Return value
None

Usage
If AutoCommit is set to true or 0, then transactions are committed immediately and calling the Commit method has no effect.

Examples
This example updates the database and commits the transaction if no errors occurred:

```java
    dw_1.Update( );
    if (trans_1.GetSQLCode( ) == 0) {
        trans_1.Commit( );
    }
```

See also
GetSQLCode
Rollback
Properties of the Transaction Object control

Connect

Description
Connects to the DBMS specified in the connection string of the dbParm property.

Applies to
Web ActiveX Transaction Object control

Syntax
void transaction.Connect( )

Return value
None

Usage
In addition to connecting to the DBMS, you must call SetTransObject to associate the transaction object with the Web ActiveX. You can do this before or after connecting.

If GetSQLCode reports that an error occurred while connecting, check the value returned by GetDBCode to find out more about the error.
Examples

This example connects to the DBMS, then associates the transaction object with the Web ActiveX named dw_1:

```javascript
trans_1.Connect();
if (trans_1.GetSQLCode() != 0) {
    alertBox("Cannot connect to database");
} else {
    dw_1.SetTransObject(trans_1);
}
```

See also

GetSQLCode
GetDBCode
Disconnect
Properties of the Transaction Object control

**Disconnect**

**Description**

Executes a commit, then disconnects from the DBMS.

**Applies to**

Web ActiveX Transaction Object control

**Syntax**

```javascript
void transaction.Disconnect()
```

**Return value**

None

**Examples**

This example disconnects from the DBMS:

```javascript
trans_1.Disconnect();
```

See also

Connect

**GetDBCode**

**Description**

Reports the database vendor’s error code when the most recent database operation resulted in an error.

**Applies to**

Web ActiveX Transaction Object control

**Syntax**

```javascript
number transaction.GetDBCode()
```

**Return value**

A number whose meaning is defined by the database vendor.

**Usage**

Call GetSQLCode to find out if an error occurred before calling GetDBCode to get details about the error.
GetSQLCode

Examples
This example checks whether an error occurred before getting the database vendor’s error code:

```java
if (trans_1.GetSQLCode() == -1) {
    errnum = trans_1.GetDBCode();
}
```

See also
GetSQLCode
GetSQLErrText
GetSQLReturnData

GetSQLCode

Description
Reports a code indicating the success or failure of the most recent database operation.

Applies to
Web ActiveX Transaction Object control

Syntax
number transaction.GetSQLCode()

Return value
Number. Possible values are:

- 0 – Success
- 100 – Not found
- -1 – Error

Usage
When GetSQLCode reports an error, call GetDBCode to get the vendor’s error code.

Examples
This example checks whether an error occurred before getting the database vendor’s error code:

```java
if (trans_1.GetSQLCode() == -1) {
    errnum = trans_1.GetDBCode();
}
```

See also
GetDBCode
GetSQLErrText
GetSQLReturnData
GetSQLErrText

Description Reports the database vendor’s error message for the most recent database operation.

Applies to Web ActiveX Transaction Object control

Syntax string transaction.GetSQLErrText()

Return value String. The text of the error message.

Usage Call GetSQLCode to find out if an error occurred before calling GetDBCode and GetSQLErrText to get details about the error.

Examples This example checks whether an error occurred before getting the database vendor’s error code:

```java
if (trans_1.GetSQLCode() == -1) {
    errnum = trans_1.GetDBCode();
    errstring = trans_1.GetSQLErrText();
}
```

See also GetDBCode

GetSQLCode

GetSQLReturnData

GetSQLNRows

Description Reports the number of rows affected by the most recent database operation.

Applies to Web ActiveX Transaction Object control

Syntax number transaction.GetSQLNRows()

Return value Number. The number of affected rows.

Usage The number of rows is supplied by the database vendor, so the meaning may not be the same in every DBMS.

Examples This example updates the database and, if no errors occurred, reports the number of rows affected:

```java
dw_1.Update();
if (trans_1.GetSQLCode() == 0) {
    alert("Rows updated: " + trans_1.GetSQLNRows());
}
```
GetSQLReturnData

Description
Returns information reported by the DBMS for the most recent database operation.

Applies to Web ActiveX Transaction Object control

Syntax number transaction.GetSQLReturnData()

Return value Number. A value whose meaning is determined by the database vendor.

Usage The numeric return value is different from the value of the SQLReturnData property for the PowerBuilder Transaction object. The PowerBuilder property is a string.

See also GetDBCode GetSQLCode GetSQLErrText

Rollback

Description Rolls back all database changes since the last commit.

Applies to Web ActiveX Transaction Object control

Syntax void transaction.Rollback()

Return value None

Usage If AutoCommit is set to true or 0, then transactions are committed immediately and calling the Rollback method has no effect.

Examples This example updates the database but rolls back the transaction if an error occurred:

\[
\begin{align*}
\text{dw}_1 & . \text{Update}( ) ; \\
\text{if} & \ ( \text{trans}_1 . \text{GetSQLCode}( ) \ != \ 0) \ \{ \\
& \quad \text{trans}_1 . \text{Rollback}( ) ; \\
& \}
\end{align*}
\]

Space function 132
spaces deleting leading 86
deleting trailing 125
inserting in a string 132
removing from strings 144
Spacing property 372
Sparse property 372
special characters in strings 446
Specify filter dialog box 840
Specify Sort Columns dialog 879
Spin (EditMask.property) 246
SpinIncr (EditMask.property) 246
SpinRange (EditMask.property) 246
SQL Anywhere 737
SQL statements and modification status 668
and SetTrans method 887
and SetTransObject method 891
and Update method 916
changing during execution 880, 881
CONNECT 774
modifying WHERE clause of SELECT 729
previewing 693, 694
saving DataWindow SQL 787
SELECT and sharing data 903
SELECT, obtaining 597
specifying retrieval arguments 773
SQLCA 892
SQLInsert constant 486
SQLPreview event 557, 693, 700, 880
SQLPreviewFunction enumerated data type 488
SQLPreviewType enumerated data type 489
SQLSelect (Table.property) 378
Sqrt function 132
Square constant 480
square fill pattern 480
square root 132
stack faults, avoiding 834, 917
standard deviation 133, 135
StateIconAlignMode (Tree.property) 393
StaticMode (Crosstab.property) 213
status changing 771, 854
of rows and columns 668, 700
StDev function 133
StDevP function 135
Storage property 373
String function 137
string functions

StringJSFile (HTMLGen.property) 291
strings
  comparing 8
  concatenating 10
  converting 60, 89, 107, 119
  deleting leading spaces 86
  detecting contents 75, 77, 79
  extracting 98, 99
  finding substrings 114, 115
  importing data from 714
  lowercase 90
  retrieving from buffers 654, 670
  uppercase 145
StripRTF function 140
structure of DataWindow 597
Style (Edit.property) 241
Style (Pen.property) 329
Style keyword, table of DataWindow object properties 171
style, border 636
StyleBox constant 476
StyleLowered constant 476
StyleRaised constant 476
StyleShadowBox constant 476
StyleSheet (HTMLTable.property) 299
substring
  extracting 98, 99
  finding 114, 115
  replacing 121, 122
subtraction operator 5
Sum function 140
Summary properties. See Bandname properties
summary, moving objects to 861
Suppress (Bandname.property) 193
SuppressEventProcessing property 374
SuppressEvents property (Web ActiveX) 498
SYLK constant 486
Symbol constants for graphs 483
symbol types in graphs, for data points 936, 971, 972
Syntax property 375
syntax, for creating objects 741
Syntax.Data property 375
Syntax.Modified property 376
System and environment functions
  ProfileInt 115
  ProfileString 117
system date 143
system time 106

T
  tab character
    in PowerBuilder 447
    property expression syntax 443
  tab order 883
TabDownOut event 559
TabIndexBase (HTMLGen.property) 291
Table properties 378
Table property
  Create function 376
  InkPicture objects 377
  TableBlob objects 377
Table SQLAction properties 382
TableBlob controls, table of DataWindow object properties 171
tables, database
  accessing multiple 888
