# **Contents**

About This Book.		vi
CHAPTER 1	Selecting Data from Database Tables	1
	Viewing table information	
	Ordering query results	
	Selecting columns and rows	
	Using search conditions	
	Comparing dates in queries	
	Compound search conditions in the WHERE clause	
	Pattern matching in search conditions	
	Matching rows by sound	
	Short cuts for typing search conditions	
	Obtaining aggregate data	
	A first look at aggregate functions	
	Using aggregate functions to obtain grouped data	
	Restricting groups	
	Improving subtotal calculation	
	Obtaining analytical data	
	Eliminating duplicate rows	
CHAPTER 2	Joining Tables	19
	Joining tables with the cross product	
	Restricting a join	
	How tables are related	
	Rows are identified by a primary key	
	Tables are related by a foreign key	
	Join operators	
	Joining tables using key joins	
	Joining tables using natural joins	
	Ad hoc joins vs. using join indexes	
	Joins and data types	
	Support for joins between stores or databases	
	Querying remote and heterogeneous databases	

	Replacing joins with subqueries	28
CHAPTER 3	Improving Query Performance	31
	Tips for structuring queries	
	Impact on query performance of GROUP BY over a UNION 32	I ALL
	Conditions that cause processing by Adaptive Server Anyw 34	here
	Planning queries	35
	Query evaluation options	35
	The query tree	36
	Using the HTML query plan	37
	Controlling query processing	37
	Setting query time limits	37
	Setting query priority	38
	Setting query optimization options	38
CHAPTER 4	Managing System Resources	41
	Introduction to performance terms	
	Designing for performance	
	Overview of memory use	
	Paging increases available memory	
	Utilities to monitor swapping	
	Server memory	
	Managing buffer caches	
	Determining the sizes of the buffer caches	
	Setting buffer cache sizes	
	Specifying page size	
	Saving memory	
	Optimizing for large numbers of users	
	Platform-specific memory options	
	Other ways to get more memory	
	The process threading model	
	Insufficient threads error	
	IQ options for managing thread usage	
	Balancing I/O	
	Raw I/O (on UNIX operating systems)	
	Using disk striping	
	Internal striping	
	Using multiple dbspaces	
	Strategic file locations	
	Working space for inserting, deleting, and synchronizing	
	Setting reserved space options	
	30g .000.700 opa00 opa00	, 0

vi Sybase IQ

### **About This Book**

Sybase<sup>®</sup> IQ is a high-performance decision support server designed specifically for data warehouses and data marts. This book, *Sybase IQ Performance and Tuning Guide*, presents performance and tuning recommendations.

#### **Audience**

This guide is for system and database administrators who need to understand performance issues. Familiarity with relational database systems and introductory user-level experience with Sybase IQ is assumed. Use this guide in conjunction with other manuals in the documentation set.

#### How to use this book

The following table shows which chapters fit a particular interest or need.

Table 1: Guide to using this book

To learn how to	Read this chapter
Structure SELECT statements	Chapter 1, "Selecting Data from Database Tables"
Compose joins	Chapter 2, "Joining Tables"
Optimize queries	Chapter 3, "Improving Query Performance"
Adjust memory, disk I/O and CPUs	Chapter 4, "Managing System Resources"
Monitor and tune performance	Chapter 5, "Monitoring and Tuning Performance"
Tune Windows servers for performance	Chapter 6, "Tuning Servers on Windows Systems"

#### Related documents

#### Documentation for Sybase IQ:

- Introduction to Sybase IQ.
  - Read and try the hands-on exercises if you are unfamiliar with Sybase IQ, with the Sybase Central<sup>TM</sup> database management tool.
- New Features in Sybase IQ 12.6
  - Read just before or after purchasing Sybase IQ for a list of new features.
- Sybase IQ Reference Manual
  - Read for a full description of the SQL language, stored procedures, data types, and system tables supported by Sybase IQ.
- Sybase IQ System Administration Guide

Read to manage the IQ Store.

• Sybase IQ Troubleshooting and Error Messages Guide

Read to solve problems, perform system recovery and database repair, and understand both IQ error messages which are referenced by SQLCode, SQLState and message text, and SQL preprocessor errors and warnings.

• Sybase IQ Utility Guide

Read for Sybase IQ utility program reference material, such as available syntax, parameters, and options.

Large Objects Management in Sybase IQ

Read to understand storage and retrieval of Binary Large Objects (BLOBs) and Character Large Objects (CLOBs) within the Sybase IQ data repository. You need a separate license to install this product option.

Sybase IQ Installation and Configuration Guide

Read the edition for your platform before and while installing Sybase IQ, when migrating to a new version of Sybase IQ, or when configuring Sybase IQ for a particular platform.

• Sybase IQ Release Bulletin

Read just before or after purchasing Sybase IQ for last minute changes to the product and documentation. Read for help if you encounter a problem.

**Note** Because Sybase IQ is an extension of Adaptive Server® Anywhere, a component of SQL Anywhere® Studio, IQ supports many of the same features as Adaptive Server Anywhere. The IQ documentation set refers you to SQL Anywhere Studio documentation where appropriate.

Documentation for Adaptive Server Anywhere:

• Adaptive Server Anywhere Programming Guide

Intended for application developers writing programs that directly access the ODBC, Embedded SQL<sup>TM</sup>, or Open Client<sup>TM</sup> interfaces, this book describes how to develop applications for Adaptive Server Anywhere.

Adaptive Server Anywhere Database Administration Guide
 Intended for all users, this book covers material related to running,

managing, and configuring databases and database servers.

Adaptive Server Anywhere Error Messages

viii Sybase IQ

This book lists all Adaptive Server Anywhere error messages with diagnostic information.

Adaptive Server Anywhere SQL Reference Manual

Intended for all users, this book provides a complete reference for the SQL language used by Adaptive Server Anywhere. It also describes the Adaptive Server Anywhere system tables and procedures.

You can also refer to the Adaptive Server Anywhere documentation in the SQL Anywhere Studio 9.0.1 collection on the Sybase Product Manuals Web site. To access this site, go to Product Manuals at http://www.sybase.com/support/manuals/.

## Other sources of information

Use the Sybase Getting Started CD, the SyBooks CD, and the Sybase Product Manuals Web site to learn more about your product:

- The Getting Started CD contains release bulletins and installation guides in PDF format, and may also contain other documents or updated information not included on the SyBooks CD. It is included with your software. To read or print documents on the Getting Started CD, you need Adobe Acrobat Reader, which you can download at no charge from the Adobe Web site using a link provided on the CD.
- The SyBooks CD contains product manuals and is included with your software. The Eclipse-based SyBooks browser allows you to access the manuals in an easy-to-use, HTML-based format.

Some documentation may be provided in PDF format, which you can access through the PDF directory on the SyBooks CD. To read or print the PDF files, you need Adobe Acrobat Reader.

Refer to the *SyBooks Installation Guide* on the Getting Started CD, or the *README.txt* file on the SyBooks CD for instructions on installing and starting SyBooks.

• The Sybase Product Manuals Web site is an online version of the SyBooks CD that you can access using a standard Web browser. In addition to product manuals, you will find links to EBFs/Maintenance, Technical Documents, Case Management, Solved Cases, newsgroups, and the Sybase Developer Network.

To access the Sybase Product Manuals Web site, go to Product Manuals at http://www.sybase.com/support/manuals/.

# Sybase certifications on the Web

Technical documentation at the Sybase Web site is updated frequently.

#### ❖ Finding the latest information on product certifications

- 1 Point your Web browser to Technical Documents at http://www.sybase.com/support/techdocs/.
- 2 Select Products from the navigation bar on the left.
- 3 Select a product name from the product list and click Go.
- 4 Select the Certification Report filter, specify a time frame, and click Go.
- 5 Click a Certification Report title to display the report.

#### Creating a personalized view of the Sybase Web site (including support pages)

Set up a MySybase profile. MySybase is a free service that allows you to create a personalized view of Sybase Web pages.

- Point your Web browser to Technical Documents at http://www.sybase.com/support/techdocs/.
- 2 Click MySybase and create a MySybase profile.

# Sybase EBFs and software maintenance

#### Finding the latest information on EBFs and software maintenance

- 1 Point your Web browser to the Sybase Support Page at http://www.sybase.com/support.
- 2 Select EBFs/Maintenance. If prompted, enter your MySybase user name and password.
- 3 Select a product.
- 4 Specify a time frame and click Go. A list of EBF/Maintenance releases is displayed.

Padlock icons indicate that you do not have download authorization for certain EBF/Maintenance releases because you are not registered as a Technical Support Contact. If you have not registered, but have valid information provided by your Sybase representative or through your support contract, click Edit Roles to add the "Technical Support Contact" role to your MySybase profile.

5 Click the Info icon to display the EBF/Maintenance report, or click the product description to download the software.

#### **Syntax conventions**

This documentation uses the following syntax conventions in syntax descriptions:

X Sybase IQ

- **Keywords** SQL keywords are shown in UPPER CASE. However, SQL keywords are case insensitive, so you can enter keywords in any case you wish; SELECT is the same as Select which is the same as select.
- **Placeholders** Items that must be replaced with appropriate identifiers or expressions are shown in *italics*.
- **Continuation** Lines beginning with ... are a continuation of the statements from the previous line.
- **Repeating items** Lists of repeating items are shown with an element of the list followed by an ellipsis (three dots). One or more list elements are allowed. If more than one is specified, they must be separated by commas.
- **Optional portions** Optional portions of a statement are enclosed by square brackets. For example:

```
RELEASE SAVEPOINT [ savepoint-name ]
```

It indicates that the *savepoint-name* is optional. The square brackets should not be typed.

• **Options** When none or only one of a list of items must be chosen, the items are separated by vertical bars and the list enclosed in square brackets. For example:

```
[ ASC | DESC ]
```

It indicates that you can choose one of ASC, DESC, or neither. The square brackets should not be typed.

• **Alternatives** When precisely one of the options must be chosen, the alternatives are enclosed in curly braces. For example:

```
QUOTES { ON | OFF }
```

It indicates that exactly one of ON or OFF must be provided. The braces should not be typed.

# Typographic conventions

Table 2 lists the typographic conventions used in this documentation.

Table 2: Typographic conventions

Item	Description
Code	SQL and program code is displayed in a mono-spaced (fixed-width) font.
User entry	Text entered by the user is shown in bold serif type.
emphasis	Emphasized words are shown in italic.
file names	File names are shown in italic.
database objects	Names of database objects, such as tables and procedures, are shown in bold, san-serif type in print, and in italic online.

# The sample database

Sybase IQ includes a sample database, which many of the examples in the IQ documentation use.

The sample database represents a small company. It contains internal information about the company (employees, departments, and financial data), as well as product information (products), sales information (sales orders, customers, and contacts), and financial information (fin code, fin data).

The sample database is held in a file named *asiqdemo.db*, located in the directory \$ASDIR/demo on UNIX systems and %ASDIR%\demo on Windows systems.

# Accessibility features

This document is available in an HTML version that is specialized for accessibility. You can navigate the HTML with an adaptive technology such as a screen reader, or view it with a screen enlarger.

Sybase IQ 12.5.1 and the HTML documentation have been tested for compliance with U.S. government Section 508 Accessibility requirements. Documents that comply with Section 508 generally also meet non-U.S. accessibility guidelines, such as the World Wide Web Consortium (W3C) guidelines for Web sites.

xii Sybase IQ

For information about accessibility support in the Sybase IQ plug-in for Sybase Central, see "Using accessibility features" in *Introduction to Sybase IQ*. The online help for this product, which you can navigate using a screen reader, also describes accessibility features, including Sybase Central keyboard shortcuts.

**Note** You might need to configure your accessibility tool for optimal use. Some screen readers pronounce text based on its case; for example, they pronounce ALL UPPERCASE TEXT as initials, and MixedCase Text as words. You might find it helpful to configure your tool to announce syntax conventions. Consult the documentation for your tool and see "Using screen readers" in *Introduction to Sybase IQ*.

For information about how Sybase supports accessibility, see Sybase Accessibility at http://www.sybase.com/accessibility. The Sybase Accessibility site includes links to information on Section 508 and W3C standards.

For a Section 508 compliance statement for Sybase IQ, go to Sybase Accessibility at http://www.sybase.com/products/accessibility.

If you need help

Each Sybase installation that has purchased a support contract has one or more designated people who are authorized to contact Sybase Technical Support. If you cannot resolve a problem using the manuals or online help, please have the designated person contact Sybase Technical Support or the Sybase subsidiary in your area.

xiv Sybase IQ

# CHAPTER 1 Selecting Data from Database Tables

#### About this chapter

This chapter reviews basic query construction and recommends some refinements to take advantage of product design. You will complete tutorial tasks on looking at table contents, ordering query results, selecting columns, selecting rows, and using search conditions to refine queries.

For advanced query performance recommendations, see Chapter 3, "Improving Query Performance."

If you use a graphical front-end tool instead of DBISQL to query your database, the tool may allow you to view the SQL syntax it generates. For example, in InfoMaker, you can view SQL statements by choosing the SQL Syntax button on the Table painter bar.

This tutorial introduces the SELECT statement used to retrieve information from databases. SELECT statements are commonly called queries, because they ask the database server about information in a database.

**Note** The SELECT statement is a versatile command. SELECT statements can become highly complex in applications retrieving very specific information from large databases. This tutorial uses only simple SELECT statements: later tutorials describe more advanced queries. For more information about the full syntax of the select statement, see the SELECT statement in Chapter 6, "SQL Statements," in the *Sybase IQ Reference Manual*.

Ideally, you should be running Sybase IQ software on your computer while you read and work through the tutorial lessons.

This tutorial assumes that you have already started DBISQL and connected to the sample database. If you have not already done so, see Chapter 2, "Using Interactive SQL (dbisql)" in the *Sybase IQ Utility Guide*.

## Viewing table information

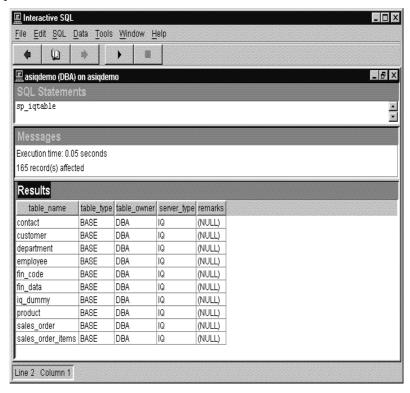

In this section, you will look at the data in the *employee* table.

The sample database you use in this tutorial is the same fictional company as in the previous chapter. The database contains information about employees, departments, sales orders, and so on. All the information is organized into tables.

Listing tables

In *Introduction to Sybase IQ*, you learned how to display a list of tables by opening the Tables folder in Sybase Central. You can also list user tables from interactive SQL using a system stored procedure, sp\_iqtable. System stored procedures are system functions that are implemented as stored procedures in Sybase IQ.

In the SQL Statements window, type sp\_iqtable to run the system stored procedure of the same name.

For complete details about this and other system stored procedures, see Chapter 9, "System Procedures," in the *Sybase IQ Reference Manual*.

# Using the SELECT statement

In this lesson, you view one of the tables in the database. The command used will look at everything in a table called employee.

Execute the command:

SELECT \* FROM employee

The asterisk is a short form for all the columns in the table.

The SELECT statement retrieves all the rows and columns of the employee table, and the DBISQL Results window lists those that will fit:

emp_id	manager_id	emp_fname	emp_Ina me	dept_id
102	501	Fran	Whitney	100
105	501	Matthew	Cobb	100
129	902	Philip	Chin	200
148	1293	Julie	Jordan	300
160	501	Robert	Breault	100

The employee table contains a number of **rows** organized into **columns**. Each column has a name, such as emp\_lname or emp\_id. There is a row for each employee of the company, and each row has a value in each column. For example, the employee with employee ID 102 is Fran Whitney, whose manager is employee ID 501.

You will also see some information in the DBISQL Messages window. This information is explained later.

Case sensitivity

The table name employee is shown starting with an upper case E, even though the real table name is all lower case. Sybase IQ databases can be created as case-sensitive or case-insensitive (the default) in their string comparisons, but are always case insensitive in their use of identifiers.

**Note** The examples in this book were created case-insensitive, using the CREATE DATABASE qualifier CASE IGNORE. The default is CASE RESPECT, which gives better performance.

For information on creating databases, see Chapter 5, "Working with Database Objects," *Adaptive Server IQ System Administration Guide*.

You can type select or Select instead of SELECT. Sybase IQ allows you to type keywords in uppercase, lowercase, or any combination of the two. In this manual, uppercase letters are generally used for SQL keywords.

Manipulation of the DBISQL environment and use of DBISQL is specific to the operating system.

For information on how to scroll through data and manipulate the DBISQL environment, see Chapter 2, "Using Interactive SQL (dbisql)" in *Sybase IQ Utility Guide*.

## **Ordering query results**

In this section, you will add an ORDER BY clause to the SELECT statement to display results in alphabetical or numerical order.

Unless otherwise requested, Sybase IQ displays the rows of a table in no particular order. Often it is useful to look at the rows in a table in a more meaningful sequence. For example, you might like to see employees in alphabetical order.

Listing employees in alphabetical order

The following example shows how adding an ORDER BY clause to the SELECT statement causes the results to be retrieved in alphabetical order.

SELECT \* FROM employee ORDER BY emp\_lname

emp_id	manager_id	emp_fname	emp_Iname	dept_id
1751	1576	Alex	Ahmed	400
1013	703	Joseph	Barker	500
591	1576	Irene	Barletta	400
191	703	Jeannette	Bertrand	500
1336	1293	Janet	Bigelow	300

Notes

The order of the clauses is important. The ORDER BY clause must follow the FROM clause and the SELECT clause.

**Note** If you omit the FROM clause, or if all tables in the query are in the SYSTEM dbspace, the query is processed by Adaptive Server Anywhere instead of Sybase IQ and may behave differently, especially with respect to syntactic and semantic restrictions and the effects of option settings. See the Adaptive Server Anywhere documentation for rules that may apply to processing.

If you have a query that does not require a FROM clause, you can force the query to be processed by Sybase IQ by adding the clause "FROM iq\_dummy," where iq\_dummy is a one row, one column table that you create in your database.

# Selecting columns and rows

Often, you are only interested in some of the columns in a table. For example, to make up birthday cards for employees you might want to see the emp\_lname, dept\_id, and birth\_date columns.

Listing last name, department, and birth date of each employee In this section, you will select each employee's birth date, last name, and department ID. Type the following:

SELECT emp\_lname, dept\_id, birth\_date
FROM employee

emp_Iname	dept_id	birth_date	
Whitney	100	1958-06-05	
Cobb	100	1960-12-04	
Chin	200	1966-10-30	
Jordan	300	1951-12-13	•••
Breault	100	1947-05-13	

Rearranging columns

The three columns appear in the order in which you typed them in the SELECT command. To rearrange the columns, simply change the order of the column names in the command. For example, to put the birth\_date column on the left, use the following command:

SELECT birth\_date, emp\_lname, dept\_id
FROM employee

#### Ordering rows

You can order rows and look at only certain columns at the same time as follows:

```
SELECT birth_date, emp_lname, dept_id FROM employee ORDER BY emp_lname
```

The asterisk in

```
SELECT * FROM employee
```

is a short form for all columns in the table.

# **Using search conditions**

In this section you will learn procedures for comparing dates, using compound search conditions in the WHERE clause, pattern matching, and search condition shortcuts.

Sometimes you will not want to see information on all the employees in the employee table. Adding a WHERE clause to the SELECT statement allows only some rows to be selected from a table.

For example, suppose you would like to look at the employees with first name John.

#### List all employees named John:

• Type the following:

```
SELECT *
FROM employee
WHERE emp_fname = 'John'
```

emp_id	manager_id	emp_fname	emp_Iname	dept_id
318	1576	John	Crow	400
862	501	John	Sheffield	100
1483	1293	John	Letiecq	300

# Apostrophes and case-sensitivity

The apostrophes (single quotes) around the name 'John' are required. They
indicate that John is a character string. Quotation marks (double quotes)
have a different meaning. Quotation marks can be used to make otherwise
invalid strings valid for column names and other identifiers.

• The sample database is not case sensitive, so you would get the same results whether you searched for ' 'JOHN', 'john', or 'John'.

Again, you can combine what you have learned:

```
SELECT emp_fname, emp_lname, birth_date
FROM employee
WHERE emp_fname = 'John'
ORDER BY birth_date
```

Notes

- How you order clauses is important. The FROM clause comes first, followed by the WHERE clause, and then the ORDER BY clause. If you type the clauses in a different order, you will get a syntax error.
- You do not need to split the statement into several lines. You can enter the statement into the SQL Statements window in any format. If you use more than the number of lines that fit on the screen, the text scrolls in the SQL Statements window.

### Comparing dates in queries

Sometimes you will not know exactly what value you are looking for, or you would like to see a set of values. You can use comparisons in the WHERE clause to select a set of rows that satisfy the search condition.

Listing employees born before March 3, 1964 The following example shows the use of a date inequality search condition. Type the following:

```
SELECT emp_lname, birth_date
FROM employee
WHERE birth_date < 'March 3, 1964'</pre>
```

emp_Iname	birth_date
Whitney	1958-06-05 00:00:00.000
Cobb	1960-12-04 00:00:00.000
Jordan	1951-12-13 00:00:00.000
Breault	1947-05-13 00:00:00.000
Espinoza	1939-12-14 00:00:00.000
Dill	1963-07-19 00:00:00.000

Sybase IQ knows that the birth\_date column contains a date, and converts 'March 3, 1964' to a date automatically.

### Compound search conditions in the WHERE clause

So far, you have seen equal (=) and less than (<) as comparison operators. Sybase IQ also supports other comparison operators, such as greater than (>), greater than or equal (>=), less than or equal (<=), and not equal (<>).

These conditions can be combined using AND and OR to make more complicated search conditions.

Qualifying the list

To list all employees born before March 3, 1964, but exclude the employee named Whitney, type:

```
SELECT emp_lname, birth_date
FROM employee
WHERE birth_date < '1964-3-3'
AND emp_lname <> 'Whitney'
```

emp_Iname	birth_date
Cobb	1960-12-04 00:00:00.000
Jordan	1951-12-13 00:00:00.000
Breault	1947-05-13 00:00:00.000
Espinoza	1939-12-14 00:00:00.000
Dill	1963-07-19 00:00:00.000
Francis	1954-09-12 00:00:00.000

### Pattern matching in search conditions

Another useful way to look for things is to search for a pattern. In SQL, the word LIKE is used to search for patterns. The use of LIKE can be explained by example.

Listing employees whose surname begins with BR

Type the following:

```
SELECT emp_lname, emp_fname
FROM employee
WHERE emp_lname LIKE 'br%'
```

emp_Iname	emp_fname
Breault	Robert
Braun	Jane

The % in the search condition indicates that any number of other characters may follow the letters BR.

#### Qualifying the surname search

To list all employees whose surname begins with BR, followed by zero or more letters and a T, followed by zero or more letters, type:

```
SELECT emp_lname, emp_fname
FROM employee
WHERE emp_lname LIKE 'BR%T%'
```

emp_Iname	emp_fname
Breault	Robert

The first % sign matches the string "eaul", while the second % sign matches the empty string (no characters).

Another special character that can be used with LIKE is the \_ (underscore) character, which matches exactly one character.

The pattern BR\_U% matches all names starting with BR and having U as the fourth letter. In Braun the \_ matches the letter A and the% matches N.

### Matching rows by sound

With the SOUNDEX function, you can match rows by sound, as well as by spelling. For example, suppose a phone message was left for a name that sounded like "Ms. Brown". Which employees in the company have names that sound like Brown?

# Searching surnames by sound

To list employees with surnames that sound like Brown, type the following:

```
SELECT emp_lname, emp_fname
FROM employee
WHERE SOUNDEX( emp_lname ) = SOUNDEX( 'Brown' )
```

emp_Iname	emp_fname
Braun	Jane

Jane Braun is the only employee matching the search condition.

### Short cuts for typing search conditions

Using the short form BETWEEN

SQL has two short forms for typing in search conditions. The first, BETWEEN, is used when you are looking for a range of values. For example,

```
SELECT emp_lname, birth_date
FROM employee
```

```
WHERE birth_date BETWEEN '1964-1-1'
AND '1965-3-31'
is equivalent to:
    SELECT emp_lname, birth_date
    FROM employee
    WHERE birth_date >= '1964-1-1'
    AND birth_date <= '1965-3-31'</pre>
```

Using the short form IN

The second short form, IN, may be used when looking for one of a number of values. The command

```
SELECT emp_lname, emp_id
FROM employee
WHERE emp_lname IN ('Yeung','Bucceri','Charlton')
```

means the same as:

```
SELECT emp_lname, emp_id

FROM employee

WHERE emp_lname = 'Yeung'

OR emp_lname = 'Bucceri'

OR emp_lname = 'Charlton'
```

### **Obtaining aggregate data**

This section tells how to construct queries that give you aggregate information. Examples of aggregate information are:

- The total of all values in a column
- The number of entries in a column
- The average value of entries in a column

### A first look at aggregate functions

Suppose you want to know how many employees there are. The following statement retrieves the number of rows in the employee table:

```
SELECT count( * )
FROM employee
```

```
count( * )
```

The result returned from this query is a table with only one column (with title count(\*)) and one row, which contains the number of employees.

The following command is a slightly more complicated aggregate query:

```
SELECT count( * ),
min( birth_date ),
max( birth_date )
FROM employee
```

count( * )	min( birth_date )	max( birth_date )
75	1936-01-02	1973-01-18

The result set from this query has three columns and only one row. The three columns contain the number of employees, the birth date of the oldest employee, and the birth date of the youngest employee.

COUNT, MIN, and MAX are called **aggregate functions**. Each of these functions summarizes information for an entire table. In total, there are seven aggregate functions: MIN, MAX, COUNT, AVG, SUM, STDDEV, and VARIANCE. All of the functions have either the name of a column or an expression as a parameter. As you have seen, COUNT also has an asterisk as its parameter.

### Using aggregate functions to obtain grouped data

In addition to providing information about an entire table, aggregate functions can be used on groups of rows.

Using an aggregate function on groups of rows

To list the number of orders for which each sales representative is responsible, type:

```
SELECT sales_rep, count( * )
FROM sales_order
GROUP BY sales_rep
```

sales_rep	count( * )
129	57
195	50
299	114
467	56

sales_rep	count( * )
667	54

The results of this query consist of one row for each sales\_rep ID number, containing the sales\_rep ID, and the number of rows in the sales\_order table with that ID number.

Whenever GROUP BY is used, the resulting table has one row for each different value found in the GROUP BY column or columns.

### Restricting groups

You have already seen how to restrict rows in a query using the WHERE clause. You can restrict GROUP BY clauses by using the HAVING keyword.

Restricting GROUP BY clauses

To list all sales reps with more than 55 orders, type:

```
SELECT sales_rep, count( * )
FROM sales_order
GROUP BY sales_rep
HAVING count( * ) > 55
```

sales_rep	count( * )
129	57
299	114
467	56
1142	57

**Note** GROUP BY must always appear before HAVING. In the same manner, WHERE must appear before GROUP BY.

Using WHERE and GROUP BY

To list all sales reps with more than 55 orders and an ID of more than 1000, type:

```
SELECT sales_rep, count( * )
FROM sales_order
WHERE sales_rep > 1000
GROUP BY sales_rep
HAVING count( * ) > 55
```

The IQ query optimizer moves predicates from the HAVING clause to the WHERE clause, when doing so provides a performance gain. For example, if you specify:

```
GROUP BY sales_rep
HAVING count( *) > 55
AND sales rep > 1000
```

instead of the WHERE clause in the preceding example, the query optimizer moves the predicate to a WHERE clause.

Sybase IQ performs this optimization with simple conditions (nothing involving OR or IN). For this reason, when constructing queries with both a WHERE clause and a HAVING clause, you should be careful to put as many of the conditions as possible in the WHERE clause.

### Improving subtotal calculation

If you have data that varies across dimensions such as date or place, you may need to determine how the data varies in each dimension. You can use the ROLLUP and CUBE operators to create multiple levels of subtotals and a grand total from a list of references to grouping columns. The subtotals "roll up" from the most detailed level to the grand total. For example, if you are analyzing sales data, you can compute an overall average and the average sales by year using the same query.

Using ROLLUP

To select total car sales by year, model and color:

```
SELECT year, model, color, sum(sales)
FROM sales_tab
GROUP BY ROLLUP (year, model, color);
```

year	model	color	sales
1990	Chevrolet	red	5
1990	Chevrolet	white	87
1990	Chevrolet	blue	62
1990	Chevrolet	NULL	154
1990	Ford	blue	64
1990	Ford	red	62
1990	Ford	white	63
1990	Ford	NULL	189
1990	NULL	NULL	343
1991	Chevrolet	blue	54
1991	Chevrolet	red	95
1991	Chevrolet	white	49
1991	Chevrolet	NULL	198

year	model	color	sales
1991	Ford	blue	52
1991	Ford	red	55
1991	Ford	white	9
1991	Ford	NULL	116
1991	NULL	NULL	314
NULL	NULL	NULL	657

When processing this query, Sybase IQ groups the data first by all three specified grouping expressions (year, model, color), then for all grouping expressions except the last one (color). In the fifth row, NULL indicates the ROLLUP value for the color column, in other words, the total number of sales of that model in all colors. 343 represents the total sales of all models and colors in 1990 and 314 is the total for 1991. The last row represents total sales on all years, all models and all colors.

ROLLUP requires an ordered list of grouping expressions as arguments. When listing groups that contain other groups, list the larger group first (such as state before city.)

You can use ROLLUP with the aggregate functions: SUM, COUNT, AVG, MIN, MAX, STDDEV, and VARIANCE. ROLLUP does not support COUNT DISTINCT and SUM DISTINCT, however.

The following query uses data from a census, including the state (geographic location), gender, education level, and income of people. You can use the CUBE extension of the GROUP BY clause, if you want to compute the average income in the entire census of state, gender, and education and compute the average income in all possible combinations of the columns state, gender, and education, while making only a single pass through the census data in the table census. For example, use the CUBE operator if you want to compute the average income of all females in all states, or compute the average income of all people in the census according to their education and geographic location.

When CUBE calculates a group, CUBE puts a NULL value in the column(s) whose group is calculated. The distinction is difficult between the type of group each row represents and whether the NULL is a NULL stored in the database or a NULL resulting from CUBE. The GROUPING function solves this problem by returning 1, if the designated column has been merged to a higher level group.

The following query illustrates the use of the GROUPING function with GROUP BY CUBE.

SELECT

Using CUBE

```
CASE GROUPING ( state ) WHEN 1 THEN 'ALL' ELSE state END AS c_state,

CASE GROUPING ( gender ) WHEN 1 THEN 'ALL' ELSE gender END AS c_gender,

CASE GROUPING ( education ) WHEN 1 THEN 'ALL' ELSE education END AS c_education,

COUNT(*), CAST (ROUND ( AVG ( income ), 2 ) AS NUMERIC (18,2)) AS average

FROM census

GROUP BY CUBE (state, gender, education);
```

The results of this query are shown below. Note that the NULLs generated by CUBE to indicate a subtotal row are replaced with ALL in the subtotal rows, as specified in the query.

c_state	c_gender	c_education	count(*)	average
MA	f	BA	3	48333.33
MA	f	HS	2	40000.00
MA	f	MS	1	45000.00
MA	f	ALL	6	45000.00
MA	m	BA	4	55000.00
MA	m	HS	1	55000.00
MA	m	MS	3	85000.00
MA	m	ALL	8	66250.00
MA	ALL	ALL	14	57142.86
NH	f	HS	2	50000.00
NH	f	MS	1	85000.00
NH	f	ALL	3	61666.67
NH	m	BA	3	55000.00
NH	m	MS	1	49000.00
NH	m	ALL	4	53500.00
NH	ALL	ALL	7	57000.00
ALL	ALL	ALL	21	57095.24
ALL	ALL	BA	10	53000.00
ALL	ALL	MS	6	72333.33
ALL	ALL	HS	5	47000.00
ALL	f	ALL	9	50555.56
ALL	m	ALL	12	62000.00
ALL	f	BA	3	48333.33
ALL	m	HS	1	55000.00
ALL	m	MS	4	76000.00

c_state	c_gender	c_education	count(*)	average
ALL	m	BA	7	55000.00
ALL	f	MS	2	65000.00
ALL	f	HS	4	45000.00
NH	ALL	HS	2	50000.00
NH	ALL	MS	2	67000.00
MA	ALL	MS	4	75000.00
MA	ALL	HS	3	45000.00
MA	ALL	BA	7	52142.86
NH	ALL	BA	3	55000.00

Data warehouse administrators find ROLLUP and CUBE particularly useful for operations like:

- Subtotaling on a hierarchical dimension like geography or time, for example year/month/day or country/state/city
- Populating summary tables

ROLLUP and CUBE allow you to use one query to compute data using multiple levels of grouping, instead of a separate query for each level.

See the SELECT statement in Chapter 6, "SQL Statements," Sybase IQ Reference Manual, for more information on the ROLLUP and CUBE operators.

## Obtaining analytical data

This section tells how to construct queries that give you analytical information. There are two types of analytical functions: rank and inverse distribution. The rank analytical functions rank items in a group, compute distribution, and divide a result set into a number of groupings. The inverse distribution analytical functions return a k-th percentile value, which can be used to help establish a threshold acceptance value for a set of data.

The rank analytical functions are RANK, DENSE\_RANK, PERCENT\_RANK, and NTILE. The inverse distribution analytical functions are PERCENTILE\_CONT and PERCENTILE\_DISC.

Suppose you want to determine the sale status of car dealers. The NTILE function divides the dealers into four groups based on the number of cars each dealer sold. The dealers with ntile = 1 are in the top 25% for car sales.

```
SELECT dealer_name, sales,
NTILE(4) OVER ( ORDER BY sales DESC )
FROM carSales;
```

dealer_name	sales	ntile
Boston	1000	1
Worcester	950	1
Providence	950	1
SF	940	1
Lowell	900	2
Seattle	900	2
Natick	870	2
New Haven	850	2
Portland	800	3
Houston	780	3
Hartford	780	3
Dublin	750	3
Austin	650	4
Dallas	640	4
Dover	600	4

To find the top 10% of car dealers by sales, you specify NTILE(10) in the example SELECT statement. Similarly, to find the top 50% of car dealers by sales, specify NTILE(2).

NTILE is a rank analytical function that distributes query results into a specified number of buckets and assigns the bucket number to each row in the bucket. You can divide a result set into tenths (deciles), fourths (quartiles), and other numbers of groupings.

The rank analytical functions require an OVER (ORDER BY) clause. The ORDER BY clause specifies the parameter on which ranking is performed and the order in which the rows are sorted in each group. Note that this ORDER BY clause is used only within the OVER clause and is *not* an ORDER BY for the SELECT.

The OVER clause indicates that the function operates on a query result set. The result set is the rows that are returned after the FROM, WHERE, GROUP BY, and HAVING clauses have all been evaluated. The OVER clause defines the data set of the rows to include in the computation of the rank analytical function.

Similarly, the inverse distribution functions require a WITHIN GROUP (ORDER BY) clause. The ORDER BY specifies the expression on which the percentile function is performed and the order in which the rows are sorted in each group. Note that this ORDER BY clause is used only within the WITHIN GROUP clause and is *not* an ORDER BY for the SELECT. The WITHIN GROUP clause distributes the query result into an ordered data set from which the function calculates a result.

For more details on the analytical functions, see the section"Analytical functions" in Chapter 5, "SQL Functions" of the *Sybase IQ Reference Manual* For information on individual analytical functions, see the section for each function in the "SQL Functions" chapter.

## **Eliminating duplicate rows**

Result tables from SELECT statements can contain duplicate rows. You can use the DISTINCT keyword to eliminate the duplicates. For example, the following command returns many duplicate rows:

```
SELECT city, state FROM employee
```

To list only unique combinations of city and state, use this command:

```
SELECT DISTINCT city, state FROM employee
```

**Note** The ROLLUP and CUBE operators do not support the DISTINCT keyword.

This chapter provides an overview of single-table SELECT statements. For more information about single-table SELECT statements, see Chapter 5, "Working with Database Objects," in the *Adaptive Server IQ System Administration Guide*, Chapter 3, "SQL Language Elements," in the *Sybase IQ Reference Manual*, and "SELECT statement" in Chapter 6, "SQL Statements," in the *Sybase IQ Reference Manual*.

Advanced uses of the SELECT statement are described in the next chapter.

# CHAPTER 2 Joining Tables

About this chapter

This chapter explains how to look at information in more than one table and describes various types of joins. You will complete tutorial tasks on joining tables.

## Joining tables with the cross product

One of the tables in the sample database is fin\_data, which lists the financial data for the company. Each data record has a code column that tells its department and whether it is an expense or revenue record. There are 84 rows in the fin\_data table.

You can get information from two tables at the same time by listing both tables, separated by a comma, in the FROM clause of a SELECT query.

The following dbisql SELECT command lists all the data in the fin\_code and fin\_data tables:

```
SELECT *
FROM fin_code, fin_data
```

The results of this query, displayed in the dbisql data window, match every row in the fin\_code table with every row in the fin\_data table. This join is called a full cross product, also known as a cartesian product. Each row consists of all columns from the fin\_code table followed by all columns from the fin\_data table.

The cross product join is a simple starting point for understanding joins, but not very useful in itself. Subsequent sections in this chapter tell how to construct more selective joins, which you can think of as applying restrictions to the cross product table.

Example

## Restricting a join

To make a cross product join useful, you need to include only rows that satisfy some condition in the result. That condition, called the join condition, compares one column from one table to one column in the other table, using a comparison operator (=, =>, <, etc.). You thus eliminate some of the rows from the cross product result.

For example, to make the join in the preceding section useful, you could insist that the sales\_rep in the sales\_order table be the same as the one in the employee table in every row of the result. Then each row contains information about an order and the sales representative responsible for it.

Example 1

To do this, add a WHERE clause to the previous query to show the list of employees and their course registrations:

```
SELECT *
FROM sales_order, employee
WHERE sales_order.sales_rep = employee.emp_id
```

The table name is given as a prefix to identify the columns. Although not strictly required in this case, using the table name prefix clarifies the statement, and is required when two tables have a column with the same name. A table name used in this context is called a **qualifier**.

The results of this query contain only 648 rows (one for each row in the sales\_order table). Of the original 48,600 rows in the join, only 648 of them have the employee number equal in the two tables.

Example 2

The following query is a modified version that fetches only some of the columns and orders the results.

```
SELECT employee.emp_lname, sales_order.id,
sales_order.order_date
FROM sales_order, employee
WHERE sales_order.sales_rep = employee.emp_id
ORDER BY employee.emp_lname
```

If there are many tables in a SELECT command, you may need to type several qualifier names. You can reduce typing by using a correlation name.

Correlation names

A **correlation name** is an alias for a particular instance of a table. This alias is valid only within a single statement. Correlation names are created by putting a short form for a table name immediately after the table name, separated by the keyword AS. You then *must* use the short form as a qualifier instead of the corresponding table name.

```
SELECT E.emp_lname, S.id, S.order_date
```

```
FROM sales_order AS S, employee AS E
WHERE S.sales_rep = E.emp_id
ORDER BY E.emp lname
```

Here, two correlation names S and E are created for the sales\_order and employee tables.

**Note** A table name or correlation name is only needed to resolve ambiguity if two columns of different tables have the same name. If you have created a correlation name, you must use it instead of the full table name, but if you have not created a correlation name, use the full table name.

### How tables are related

To construct other types of joins, you must first understand how the information in one table is related to that in another.

The primary key for a table identifies each row in the table. Tables are related to each other using a foreign key.

This section shows how primary and foreign keys together let you construct queries from more than one table.

### Rows are identified by a primary key

Every table in the asiqdemo database has a primary key. (It is a good idea to have a primary key for each table.) A primary key is one or more columns that uniquely identify a row in the table. For example, an employee number uniquely identifies an employee—emp\_id is the primary key of the employee table.

The sales\_order\_items table is an example of a table with two columns that make up the primary key. The order ID by itself does not uniquely identify a row in the sales\_order\_items table because there can be several items in an order. Also, the line\_id number does not uniquely identify a row in the sales\_order\_items table. Both the order ID name and line\_id are required to uniquely identify a row in the sales\_order\_items table. The primary key of the table is both columns taken together.

### Tables are related by a foreign key

Several tables in the asiqdemo database refer to other tables in the database. For example, in the sales\_order table, the sales\_rep column indicates which employee is responsible for an order. Only enough information to uniquely identify an employee is kept in the sales\_order table. The sales\_rep column in the sales\_order table is a foreign key to the employee table.

Foreign key

A foreign key is one or more columns that contain candidate key values from another table. (For more about candidate keys, see Chapter 5, "Working with Database Objects" in *Adaptive Server IQ System Administration Guide*.) Each foreign key relationship in the employee database is represented graphically by an arrow between two tables. You can see these arrows in the diagram of the Sample Database, Figure 1-1 on page 11, in *Introduction to Sybase IQ*. The arrow starts at the foreign key side of the relationship and points to the candidate key side of the relationship.

## Join operators

Many common joins are between two tables related by a foreign key. The most common join restricts foreign key values to be equal to primary key values. The example you have already seen restricts foreign key values in the sales\_order table to be equal to the candidate key values in the *employee* table.

```
SELECT emp_lname, id, order_date
FROM sales_order, employee
WHERE sales_order.sales_rep = employee.emp_id
```

The query can be more simply expressed using a KEY JOIN.

### Joining tables using key joins

Key joins are an easy way to join tables related by a foreign key. For example:

```
SELECT emp_lname, id, order_date
FROM sales_order
KEY JOIN employee
```

gives the same results as a query with a WHERE clause that equates the two employee ID number columns:

```
SELECT emp_lname, id, order_date
```

```
FROM sales_order, employee
WHERE sales_order.sales_rep = employee.emp_id
```

The join operator (KEY JOIN) is just a short cut for typing the WHERE clause; the two queries are identical.

In the diagram of the asiqdemo database, in *Introduction to Sybase IQ*, foreign keys are represented by lines between tables. Anywhere that two tables are joined by a line in the diagram, you can use the KEY JOIN operator. Remember that your application must enforce foreign keys in order to ensure expected results from queries based on key joins.

Joining two or more tables

Two or more tables can be joined using join operators. The following query uses four tables to list the total value of the orders placed by each customer. It connects the four tables customer, sales\_order, sales\_order\_items and product single foreign-key relationships between each pair of these tables.

```
SELECT company_name,

CAST( SUM(sales_order_items.quantity *
product.unit_price) AS INTEGER) AS value

FROM customer

KEY JOIN sales_order

KEY JOIN sales_order_items

KEY JOIN product

GROUP BY company name
```

company_name	value
McManus Inc.	3,156
Salt & Peppers.	4,980
The Real Deal	1,884
Totos Active Wear	2,496
The Ristuccia Center	4,596
•••	

The CAST function used in this query converts the data type of an expression. In this example the sum that is returned as an integer is converted to a value.

## Joining tables using natural joins

The NATURAL JOIN operator joins two tables based on common column names. In other words, Sybase IQ generates a WHERE clause that equates the common columns from each table.

Example

For example, for the following query:

```
SELECT emp_lname, dept_name
FROM employee
NATURAL JOIN department
```

the database server looks at the two tables and determines that the only column name they have in common is dept\_id. The following ON phrase is internally generated and used to perform the join:

```
FROM employee JOIN department
...
ON employee.dept_id = department.dept_id
```

Errors using NATURAL JOIN

This join operator can cause problems by equating columns you may not intend to be equated. For example, the following query generates unwanted results:

```
SELECT *
FROM sales_order
NATURAL JOIN customer
```

The result of this query has no rows.

The database server internally generates the following ON phrase:

```
FROM sales_order JOIN customer
ON sales_order.id = customer.id
```

The id column in the sales\_order table is an ID number for the order. The id column in the customer table is an ID number for the customer. None of them matched. Of course, even if a match were found, it would be a meaningless one.

You should be careful using join operators. Always remember that the join operator just saves you from typing the WHERE clause for an unenforced foreign key or common column names. Be mindful of the WHERE clause, or you may create queries that give results other than what you intend.

# Ad hoc joins vs. using join indexes

If you have defined join indexes on the join columns referenced in your query, Sybase IQ will automatically use them to make the query process faster. (For information about defining join indexes, see Chapter 6, "Using Sybase IQ Indexes,"in the *Adaptive Server IQ System Administration Guide*.)

Any join that does not use join indexes is known as an **ad hoc join**. If several tables are referenced by the query, and not all of them have join indexes defined, Sybase IQ will use the join indexes for those tables that have them in combination with an ad hoc join with the rest of the tables.

Because you cannot create join indexes for all possible joins, ad hoc joins may sometimes be necessary. Thanks to optimizations in Sybase IQ, you may find that queries perform as well or better without join indexes.

Keep these rules in mind when creating join indexes:

- Only full outer joins are supported in the index. The query can be an inner, left outer, or right outer join if indexed.
  - A full outer join is one where *all* rows from both the left and right specified tables are included in the result, with NULL returned for any column with no matching value in the corresponding column.
- The only comparison operator that may be used in the join predicate ON clause is EQUALS.
- You can use the NATURAL keyword instead of an ON clause, but you can only specify one pair of tables.
- Join index columns must have identical data type, precision, and scale.

# Joins and data types

Join columns require like data types for optimal performance. Sybase IQ allows you to make an ad hoc join on any data types for which an implicit conversion exists. Unless join column data types are identical, however, performance can suffer to varying degrees, depending on the data types and the size of the tables. For example, while you can join an INT to a BIGINT column, this join prevents certain types of optimizations. The IQ index advisor identifies performance concerns for join columns whose data types differ.

For tables of implicit data type conversions, see Chapter 7, "Moving Data In and Out of Databases" in *Adaptive Server IQ System Administration Guide*.

## Support for joins between stores or databases

This section clarifies current support for joins between stores or between databases.

Joining tables within an IQ database

Any joins within a given IQ database are supported. This means that you can join any system or user tables in the Catalog Store with any tables in the IQ Store, in any order.

Joining Adaptive Server Enterprise and IQ tables Joins of IQ tables with tables in an Adaptive Server Enterprise database are supported under the following conditions:

- The IQ database can be either the local database or the remote database.
- If an IQ table is to be used as a proxy table in ASE, the table name must be 30 characters or fewer.
- In order to join a local Adaptive Server Enterprise table with a remote Sybase IQ 12 table, the ASE version must be 11.9.2 or higher, and you must use the correct server class:
  - To connect from a front end of Adaptive Server Enterprise 12.5 or higher to a remote Sybase IQ 12.5 or higher, use the ASIQ server class, which was added in ASE 12.5.
  - To connect from a front end of Adaptive Server Enterprise 11.9.2 through 12.0 to a remote Sybase IQ 12.x (or Adaptive Server Anywhere 6.x or higher), you must use server class ASAnywhere.
- When you join a local IQ table with any remote table, the local IQ table
  must appear first in the FROM clause. This means that the local IQ table
  is the outermost table in the join.

Joins between Sybase IQ and Adaptive Server Enterprise rely on Component Integration Services (CIS).

For more information on queries from Adaptive Server Enterprise databases to Sybase IQ, see *Component Integration Services Users's Guide* in the Adaptive Server Enterprise core documentation set.

For more information on queries from Sybase IQ to other databases, see "Querying remote and heterogeneous databases."

Joining Adaptive Server Anywhere and IQ tables The CHAR data type is incompatible between Adaptive Server Anywhere and Sybase IQ when the database is built with BLANK PADDING OFF. If you want to perform cross-database joins between ASA and IQ tables using character data as the join key, use the CHAR data type with BLANK PADDING ON.

**Note** Sybase IQ CREATE DATABASE no longer supports BLANK PADDING OFF for new databases. This change has no effect on existing databases. You can test the state of existing databases using the BlankPadding database property:

```
select db_property ( 'BlankPadding' )
```

Sybase recommends that you change any existing columns affected by BLANK PADDING OFF, to ensure correct join results. Recreate join columns as CHAR data type, rather than VARCHAR. CHAR columns are always blank padded.

# Querying remote and heterogeneous databases

This section summarizes how you use IQ with Component Integration Services (CIS). CIS allows you to query Adaptive Server Enterprise databases and remote databases or nonrelational data sources through Sybase IQ. CIS is installed as part of Sybase IQ.

Using CIS, you can access tables on remote servers as if the tables were local. CIS performs joins between tables in multiple remote, heterogeneous servers and transfers the contents of one table into a supported remote server.

To query a remote database or data source, you need to map its tables to local proxy tables. CIS presents proxy tables to a client application as if the data were stored locally. When you query the tables, CIS determines the actual server storage location.

#### To join remote databases:

- 1 Create proxy tables, following the steps in the *Adaptive Server IQ System Administration Guide*.
- 2 Map the remote tables to the proxy tables.

3 Reference the proxy tables in your SELECT statement, using the proxy database name as the qualifying name for each remote table. For example:

```
SELECT a.c_custkey, b.o_orderkey
FROM proxy_asiqdemo..cust2 a,
asiqdemo..orders b
WHERE a.c_custkey = b.o_custkey
```

For more information, see Chapter 15, "Accessing Remote Data" and Chapter 16, "Server Classes for Remote Data Access" in *Adaptive Server IQ System Administration Guide*.

# Replacing joins with subqueries

A join returns a result table constructed from data from multiple tables. You can also retrieve the same result table using a subquery. A subquery is simply a SELECT statement within another select statement. This is a useful tool in building more complex and informative queries.

For example, suppose you need a chronological list of orders and the company that placed them, but would like the company name instead of their customer ID. You can get this result using a join as follows:

Using a join

To list the order\_id, order\_date, and company\_name for each order since the beginning of 1994, type:

```
SELECT sales_order.id,
sales_order.order_date,
customer.company_name
FROM sales_order
KEY JOIN customer
WHERE order_date > '1994/01/01'
ORDER BY order date
```

id	order_date	company_name
2473	1994-01-04	Peachtree Active Wear
2474	1994-01-04	Sampson & Sons
2036	1994-01-05	Hermanns
2475	1994-01-05	Salt & Peppers
2106	1994-01-05	Cinnamon Rainbows
	1	į.

Using an outer join

The join in previous sections of the tutorial is more fully called an **inner join**.

You specify an **outer join** explicitly. In this case, a GROUP BY clause is also required:

```
SELECT company_name,
MAX( sales_order.id ),state
FROM customer
KEY LEFT OUTER JOIN sales_order
WHERE state = 'WA'
GROUP BY company_name, state
```

company_name	max(sales_order.id)	state
Custom Designs	2547	WA
Its a Hit!	(NULL)	WA

Using a subquery

To list order items for products low in stock, type:

```
SELECT *
FROM sales_order_items
WHERE prod_id IN
( SELECT id
FROM product
WHERE quantity < 20 )
ORDER BY ship_date DESC
```

id	line_id	prod_id	quantity	ship_date
2082	1	401	48	1994-07-09
2053	1	401	60	1994-06-30
2125	2	401	36	1994-06-28
2027	1	401	12	1994-06-17
2062	1	401	36	1994-06-17

The subquery in the statement is the phrase enclosed in parentheses:

```
( SELECT id
FROM product
WHERE quantity < 20 )</pre>
```

By using a subquery, the search can be carried out in just one query, instead of using one query to find the list of low-stock products and a second to find orders for those products.

The subquery makes a list of all values in the id column in the product table satisfying the WHERE clause search condition.

#### Rephrasing the query

Consider what would happen if an order for ten tank tops were shipped so that the quantity column for tank tops contained the value 18. The query using the subquery would list all orders for both wool caps and tank tops. On the other hand, the first statement you used would have to be changed to the following:

```
SELECT *
FROM sales_order_items
WHERE prod_id IN ( 401, 300 )
ORDER BY ship_date DESC
```

The command using the subquery is an improvement because it still works even if data in the database is changed.

Remember the following notes about subqueries:

- Subqueries may also be useful in cases where you may have trouble constructing a join, such as queries that use the NOT EXISTS predicate.
- Subqueries can only return one column.
- Subqueries are allowed only as arguments of comparisons, IN, or EXISTS clauses.
- Subqueries cannot be used inside an outer join ON clause.

# CHAPTER 3 Improving Query Performance

About this chapter

This chapter offers query performance recommendations, including:

- Structuring queries to avoid time-consuming operations
- Using the Sybase IQ query plans
- Setting options to modify query processing

# Tips for structuring queries

Here are some hints for better query structure:

- In some cases, command statements that include subqueries can also be formulated as joins and may run faster.
- If you group on multiple columns in a GROUP BY clause, list the columns by descending order by number of unique values. This will give you the best query performance.
- Join indexes often cause join queries to execute faster than ad hoc
  joins, at the expense of using more disk space. However, when a join
  query does not reference the largest table in a multi-table join index,
  an ad hoc join usually outperforms the join index.
- You can improve performance by using an additional column to store frequently calculated results.

## Impact on query performance of GROUP BY over a UNION ALL

To improve performance, very large tables are often segmented into several small tables and accessed using a UNION ALL in a view. For certain very specific queries using such a view with a GROUP BY, the Sybase IQ optimizer is able to enhance performance by pushing some GROUP BY operations into each arm of such a UNION ALL, performing the operations in parallel, then combining the results. This method, referred to as split GROUP BY, reduces the amount of data that is processed by the top level GROUP BY, and consequently reduces query processing time.

Only certain queries with a GROUP BY over a UNION ALL show a performance improvement. The following simple query, for example, benefits from the split GROUP BY:

```
CREATE VIEW vtable (v1 int, v2 char(4)) AS
SELECT a1, a2 FROM tableA
UNION ALL
SELECT b1, b2 FROM tableB;
SELECT COUNT(*), SUM(v1) FROM vtable GROUP BY v2;
```

When analyzing this query, the optimizer first performs COUNT(\*) GROUP BY on tableA and COUNT(\*) GROUP BY on tableB, then passes these results to the top level GROUP BY. The top level GROUP BY performs a SUM of the two COUNT(\*) results, to produce the final query result. Note that the role of the top level GROUP BY changes: the aggregation used by the top level GROUP BY is SUM instead of COUNT.

Restrictions on split GROUP BY

There are some restrictions on the situations and queries that benefit from the split GROUP BY.

 The query may benefit from the split GROUP BY, if the query uses UNION ALL, rather than UNION. The following query uses GROUP BY with UNION, so it does *not* take advantage of the GROUP BY split:

```
CREATE VIEW viewA (val int, va2 int, va3 int, va4 int) AS
SELECT b1, b2, b3, b4 FROM tableB
UNION
SELECT c1, c2, c3, c4 FROM tableC;
SELECT SUM(va1) FROM viewA GROUP BY va3;
```

• The query may benefit from the split GROUP BY, if an aggregation in the query does not contain DISTINCT. The following query uses SUM DISTINCT, so it does *not* take advantage of the split GROUP BY:

```
CREATE VIEW viewA (val int, va2 int, va3 int, va4 int) AS
SELECT b1, b2, b3, b4 FROM tableB
UNION ALL
SELECT c1, c2, c3, c4 FROM tableC;
SELECT SUM(DISTINCT va1) FROM viewA GROUP BY va3;
```

 In order for the query to benefit from the split GROUP BY, you need enough memory in the temporary shared buffer cache to store the aggregation information and data used for processing the additional GROUP BY operators.

```
CREATE VIEW viewA (val int, va2 int, va3 int, va4 int) AS

SELECT b1, b2, b3, b4 FROM tableB

UNION ALL

SELECT c1, c2, c3, c4 FROM tableC

UNION ALL

SELECT d1, d2, d3, d4 FROM tableD

UNION ALL

SELECT e1, e2, e3, e4 FROM tableE

UNION ALL

SELECT f1, f2, f3, f4 FROM tableF

UNION ALL

SELECT g1, g2, g3, g4 FROM tableG;

SELECT SUM(va1) FROM viewA GROUP BY va3;
```

In this example, the IQ optimizer splits the GROUP BY and inserts six GROUP BY operators into the query plan. Consequently, the query requires more temporary cache to store aggregation information and data. If the system cannot allocate enough cache, the optimizer does not split the GROUP BY.

You can use the TEMP\_CACHE\_MEMORY\_MB database option to increase the size of the temporary cache, if memory is available. For information on setting buffer cache sizes, see the sections "Determining the sizes of the buffer caches" on page 515 and "TEMP\_CACHE\_MEMORY\_MB option" in the chapter "Database Options" of the *Sybase IQ Reference Manual*.

• In order for the query to benefit from split GROUP BY, the AGGREGATION\_PREFERENCE database option should be set to its default value of 0. This value allows the IQ optimizer to determine the best algorithm to apply to the GROUP BY. The query does *not* benefit from split GROUP BY, if the value of AGGREGATION\_PREFERENCE forces the IQ optimizer to choose a sort algorithm to process the GROUP BY. The option AGGREGATION\_PREFERENCE can be used to override the optimizer's choice of algorithm for processing the GROUP BY and should not be set to 1 or 2 in this case.

# Examples of split GROUP BY

In this example, a large table named tableA is segmented into four smaller tables: tabA1, tabA2, tabA3, and tabA4. The view unionTab is created using the four smaller tables and UNION ALL:

```
CREATE VIEW unionTab (v1 int, v2 int, v3 int, v4 int) AS SELECT a, b, c, d FROM tabA1 UNION ALL SELECT a, b, c, d FROM tabA2 UNION ALL SELECT a, b, c, d FROM tabA3 UNION ALL SELECT a, b, c, d FROM tabA4;
```

The IQ optimizer splits the GROUP BY operation in the following queries and improves query performance:

```
SELECT v1, v2, SUM(v3), COUNT(*) FROM unionTab

GROUP BY v1, v2;

SELECT v3, SUM(v1*v2) FROM unionTab

GROUP BY v3;
```

## Conditions that cause processing by Adaptive Server Anywhere

Sybase IQ architecture includes a portion of the product that processes queries according to Adaptive Server Anywhere rules. This feature, called CIS (formerly OMNI) functional compensation, allows queries not directly supported by IQ semantics to be processed, but with a major performance cost.

CIS intercepts queries that:

- Reference a user-defined function
- Include a cross-database join or proxy table
- Include certain system functions

Reference a Catalog Store table or a table created in the SYSTEM dbspace

For more information on differences between Sybase IQ and Adaptive Server Anywhere, see Appendix A, "Compatibility with Other Sybase Databases," in *Sybase IQ Reference Manual*.

# **Planning queries**

If you have created the right indexes, the Sybase IQ query optimizer can usually execute queries in the most efficient way—sometimes even if you have not used the most effective syntax. Proper query design is still important, however. When you plan your queries carefully, you can have a major impact on the speed and appropriateness of results.

Before it executes any query, the Sybase IQ query optimizer creates a query plan. Sybase IQ helps you evaluate queries by letting you examine and influence the query plan, using the options described in the sections that follow. For details of how to specify these options, see the *Sybase IQ Reference Manual*.

**Note** For all database options that accept integer values, Sybase IQ truncates any decimal *option-value* setting to an integer value. For example, the value 3.8 is truncated to 3.

## **Query evaluation options**

The following options can help you evaluate the query plan. See the *Sybase IQ Reference Manual* for details of these options.

- NOEXEC When the NOEXEC option is ON, IQ produces a query plan but does not execute the query, except when the EARLY\_PREDICATE\_EXECUTION option is ON.
- QUERY\_DETAIL When this option and either QUERY\_PLAN or QUERY\_PLAN\_AS\_HTML are both ON, Sybase IQ displays additional information about the query when producing its query plan. When QUERY\_PLAN and QUERY\_PLAN\_AS\_HTML are OFF, this option is ignored.

- QUERY\_PLAN When this option is set ON (the default), Sybase IQ
  produces messages about queries. These include messages about using
  join indexes, about the join order, and about join algorithms for the
  queries.
- QUERY\_PLAN\_AFTER\_RUN When you set this option ON, the query
  plan is printed after the query has finished running. This allows the plan to
  include additional information, such as the actual number of rows passed
  on from each node of the query. In order for this option to work,
  QUERY\_PLAN must be ON. This option is OFF by default.
- QUERY\_PLAN\_AS\_HTML This option produces a graphical query plan
  in HTML format for viewing in a Web browser. Hyperlinks between nodes
  make the HTML format much easier to use than the text format in the
  .iqmsg file. Use the QUERY\_NAME option to include the query name in the
  file name for the query plan. This option is OFF by default.
- QUERY\_PLAN\_AS\_HTML\_DIRECTORY When QUERY\_PLAN\_AS\_HTML is turned ON and a directory is specified with QUERY\_PLAN\_AS\_HTML\_DIRECTORY, Sybase IQ writes the HTML query plans in the specified directory.
- QUERY\_TIMING This option controls the collection of timing statistics
  on subqueries and some other repetitive functions in the query engine.
  Normally it should be OFF (the default) because for very short correlated
  subqueries the cost of timing every subquery execution can be very
  expensive in terms of performance.

**Note** Query plans can add a lot of text to your *.iqmsg* file. When QUERY\_PLAN is ON, and especially if QUERY\_DETAIL is ON, you will probably want to enable message log wrapping by setting IQMSG\_LENGTH\_MB to a positive value.

## The query tree

The optimizer creates a query "tree" that represents the flow of data in the query. The query plan presents the query tree in text form in the .iqmsg file, and optionally in graphical form.

The query tree consists of nodes. Each node represents a stage of work. The lowest nodes on the tree are leaf nodes. Each leaf node represents a table or a prejoin index set in the query.

At the top of the plan is the root of the operator tree. Information flows up from the tables and through any operators representing joins, sorts, filters, stores, aggregation, and subqueries.

## Using the HTML query plan

A good way to start using query plans is to set the QUERY\_PLAN\_AS\_HTML option ON. This option places a graphical version of the query plan in the same directory as the *.iqmsg* file. You can view this file in most Web browsers.

In the HTML query plan, each node in the tree is a hyperlink to the details. Each box is hyperlinked to the tree above. You can click on any node to navigate quickly through the plan.

# **Controlling query processing**

Any user can set limits on the amount of time spent processing a particular query. Users with DBA privileges can give certain users' queries priority over others, or change processing algorithms to influence the speed of query processing. See the *Sybase IQ Reference Manual* for details on the options described in this section.

## Setting query time limits

By setting the MAX\_QUERY\_TIME option, a user can disallow long queries. If a query takes longer to execute than desired, Sybase IQ stops the query with an appropriate error.

**Note** Sybase IQ truncates all decimal *option-value* settings to integer values. For example, the value 3.8 is truncated to 3.

## **Setting query priority**

Queries waiting in queue for processing are queued to run in order of the priority of the user who submitted the query, followed by the order in which the query was submitted. No queries are run from a lower priority queue until higher priority queries have all been executed.

The following options assign queries a processing priority by user.

- IQGOVERN\_PRIORITY assigns a numeric priority (1, 2, or 3, with 1 being the highest) to queries waiting in the processing queue.
- IQGOVERN\_MAX\_PRIORITY allows the DBA to set an upper boundary on IQGOVERN\_PRIORITY for a user or a group.
- IQ\_GOVERN\_PRIORITY\_TIME allows high priority users to start if a high priority (priority 1) query has been waiting in the -iqgovern queue for more than a designated amount of time.

To check the priority of a query, check the IQGovernPriority attribute returned by the sp\_iqcontext stored procedure.

## Setting query optimization options

The following options influence the speed at which queries are processed.

- AGGREGATION\_PREFERENCE Controls the choice of algorithms for processing an aggregate (GROUP BY, DISTINCT, SET functions). This option is designed primarily for internal use; do not use it unless you are an experienced database administrator.
- DEFAULT\_LIKE\_MATCH\_SELECTIVITY Sets the default selectivity for generic LIKE predicates, for example, LIKE 'string%string' where % is a wildcard character. The optimizer relies on this option when other selectivity information is not available and the match string does not start with a set of constant characters followed by a single wildcard.
- DEFAULT\_LIKE\_RANGE\_SELECTIVITY Sets the default selectivity for leading constant LIKE predicates, of the form LIKE 'string%' where the match string is a set of constant characters followed by a single wildcard character (%). The optimizer relies on this option when other selectivity information is not available.
- EARLY\_PREDICATE\_EXECUTION Controls whether simple local predicates are executed before join optimization. Under most circumstances, it should not be changed.

- IN\_SUBQUERY\_PREFERENCE Controls the choice of algorithms for processing IN subqueries. This option is designed primarily for internal use; do not use it unless you are an experienced database administrator.
- INDEX\_PREFERENCE Sets the index to use for query processing. The Sybase IQ optimizer normally chooses the best index available to process local WHERE clause predicates and other operations which can be done within an IQ index. This option is used to override the optimizer choice for testing purposes; under most circumstances it should not be changed.
- JOIN\_PREFERENCE Controls the choice of algorithms when processing joins. This option is designed primarily for internal use; do not use it unless you are an experienced database administrator.
- JOIN\_SIMPLIFICATION\_THRESHOLD Controls the minimum number of tables being joined together before any join optimizer simplifications are applied. Normally you should not need to change this value.
- MAX\_HASH\_ROWS Sets the maximum estimated number of rows the query optimizer will consider for a hash algorithm. The default is 1,250,000 rows. For example, if there is a join between two tables, and the estimated number of rows entering the join from both tables exceeds this option value, the optimizer will not consider a hash join. On systems with more than 50MB per user of TEMP\_CACHE\_MEMORY\_MB, you may want to consider a higher value for this option.
- MAX\_JOIN\_ENUMERATION Sets the maximum number of tables to be optimized for join order after optimizer simplifications have been applied. Normally you should not need to set this option.

# CHAPTER 4 Managing System Resources

About this chapter

This chapter describes the way Sybase IQ uses memory, disk I/O, and CPUs, and the relationships among these factors. It also explains how the DBA can tune performance by adjusting resource usage.

The suggestions in this chapter are generic. You need to adjust them to suit your hardware and software configuration. Recommendations for each platform are in its *Sybase IQ Installation and Configuration Guide*.

# Introduction to performance terms

Performance is the measure of efficiency of a computerized business application, or of multiple applications running in the same environment. It is usually measured in *response time* and *throughput*.

Response time is the time it takes for a single task to complete. It is affected by:

- Reducing contention and wait times, particularly disk I/O wait times
- Using faster components
- Reducing the amount of time the resources are needed (increasing concurrency)

Throughput refers to the volume of work completed in a fixed time period. Throughput is commonly measured in transactions per second (tps), but can be measured per minute, per hour, per day, and so on.

# **Designing for performance**

Most gains in performance derive from good database design, thorough query analysis, and appropriate indexing. The largest performance gains can be realized by establishing a good design and by choosing the correct indexing strategy.

Other considerations, such as hardware and network analysis, can locate bottlenecks in your installation.

# Overview of memory use

Sybase IQ uses memory for several purposes:

- Buffers for data read from disk to resolve queries
- Buffers for data read from disk when loading from flat files
- Overhead for managing connections, transactions, buffers, and database objects

The sections that follow explain how the operating system supports IQ's use of memory, how IQ allocates memory for various purposes, how you can adjust the memory allocations for better performance, and what you may need to do to configure the operating system so that enough memory is available for IQ.

## Paging increases available memory

When there is not enough memory on your system, performance can degrade severely. If this is the case, you need to find a way to make more memory available. Like any RDBMS software, Sybase IQ requires a lot of memory. The more memory you can allocate to Sybase IQ, the better.

However, there is always a fixed limit to the amount of memory in a system, so sometimes operating systems can have only part of the data in memory and the rest on disk. When the operating system must go out to disk and retrieve any data before a memory request can be satisfied, it is called *paging* or *swapping*. The primary objective of good memory management is to avoid or minimize paging or swapping.

The most frequently used operating system files are *swap files*. When memory is exhausted, the operating system swaps pages of memory to disk to make room for new data. When the pages that were swapped are called again, other pages are swapped, and the required memory pages are brought back. This is very time-consuming for users with high disk usage rates. In general, try to organize memory to avoid swapping and, thus, to minimize use of operating system files. See the section "Platform-specific memory options" on page 526 for information on configuring memory to minimize swapping.

To make the maximum use of your physical memory, Sybase IQ uses buffer caches for *all* reads and writes to your databases.

**Note** Your swap space on disk must be at least large enough to accommodate all of your physical memory.

## **Utilities to monitor swapping**

You can use the UNIX vmstat command, the UNIX sar command, or the Windows Task Manager, to get statistics on the number of running processes and the number of page-outs and swaps. Use this information to find out if the system is paging excessively. Then make any necessary adjustments. You may want to put your swap files on special fast disks.

For examples of vmstat output, see "Monitoring paging on UNIX systems."

## **Server memory**

Sybase IQ allocates memory for various purposes from a single memory pool, called *server memory*. Server memory includes all of the memory allocated for managing buffers, transactions, databases, and servers.

At the operating system level, IQ server memory consists of heap memory. For the most part, you do not need to be concerned with whether memory used by Sybase IQ is heap memory or shared memory. All memory allocation is handled automatically. However, you may need to make sure that your operating system kernel is correctly configured to use shared memory before you run Sybase IQ. See the *Sybase IQ Installation and Configuration Guide* for your platform for details.

Managing memory for multiplexes

Each server in the multiplex can be on its own host or share a host with other servers. Two or more servers on the same system consume no more CPU time than would a single combined server handling the same workload, but separate servers might need more physical memory than a single combined server, because the memory used by each server is not shared by any other server.

Memory for loads, inserts, updates, synchronizations, and deletions To avoid overallocating the physical memory on the machine, you can set the LOAD\_MEMORY\_MB database option for operations where loads occur. In addition to LOAD operations, this option affects INSERT, UPDATE, SYNCHRONIZE and DELETE operations. The LOAD\_MEMORY\_MB option sets an upper bound (in MB) on the amount of heap memory subsequent loads can use. For information on loads and buffer cache use, see "Memory requirements for loads" on page 47. For details of the LOAD\_MEMORY\_MB option, see Chapter 2, "Database Options," in the *Sybase IQ Reference Manual*.

Killing processes affects shared memory

**Warning!** Killing processes on UNIX systems may result in semaphores or shared memory being left behind instead of being cleaned up automatically. The correct way to shut down an IQ server on UNIX is the stop\_asiq utility, described in "Stopping the database server" in Chapter 2, "Running Sybase IQ," *Adaptive Server IQ System Administration Guide*. For information on using the ipcs and ipcrm to clean up after an abnormal exit, see Chapter 1, "Troubleshooting Hints," in *Sybase IQ Troubleshooting and Error Messages Guide*.

## Managing buffer caches

Sybase IQ needs more memory for buffer caches than for any other purpose. Sybase IQ has two buffer caches, one for the IQ Store and one for the Temporary Store. It uses these two buffer caches for all database I/O operations—for paging, for insertions into the database, and for backup and restore. Data is stored in one of the two caches whenever it is in memory. All user connections share these buffer caches. Sybase IQ keeps track of which data is associated with each connection.

Read the sections that follow for in-depth information on managing buffer caches:

- For information on how to calculate your memory requirements, see "Determining the sizes of the buffer caches."
- For information on how to set buffer cache sizes once you know what they should be, see "Setting buffer cache sizes."

 For an example of how to determine appropriate buffer cache sizes, see Table 12-1 on page 520.

## Determining the sizes of the buffer caches

The buffer cache sizes you specify for the IQ Store and Temporary Store will vary based on several factors. The default values (16MB for the main and 12MB for the temporary cache) are too low for most databases. The actual values required for your application depend on:

- The total amount of physical memory on your system
- How much of this memory Sybase IQ, the operating system, and other applications need to do their tasks
- Whether you are doing loads, queries, or both

Read the next several sections for guidelines in determining the best settings for your site, through the example in Table 4-1 on page 50.

The following diagram shows the relationship between the buffer caches and other memory consumption.

Operating System and Other Applications

Adaptive Server IQ Memory Overhead

Adaptive Server IQ Main Buffer Cache

Adaptive Server IQ Temp Buffer Cache

Figure 4-1: Buffer caches in relation to physical memory

The following sections describe each part in more detail and provide guidelines to help you determine how much memory each part requires.

### Operating system and other applications

This amount of memory will vary for different platforms and how the system is used. For example, UNIX file systems do more file buffering than UNIX raw partitions, so the operating system has a higher memory requirement. As a minimum, you can assume that UNIX systems use 60MB or more, while Windows systems use 30MB or more.

In addition, other applications that run in conjunction with Sybase IQ (such as query tools) have their own memory needs. See your application and operating system documentation for information on their memory requirements.

### Sybase IQ memory overhead

After determining how much physical memory the operating system and other applications use, you can calculate how much of the remaining memory Sybase IQ requires to do its tasks. The factors that affect this overhead are described in the following sections.

### Raw partitions versus file systems

For UNIX systems, databases using file systems rather than raw partitions may require another 30% of the remaining memory to handle file buffering by the operating system. On Windows, file system caching should be disabled by setting OS\_FILE\_CACHE\_BUFFERING = 'OFF' (the default for new databases). For more information, see the *Sybase IQ Installation and Configuration Guide* for your platform.

#### Multiuser database access

For multiuser queries of a database, Sybase IQ needs about 10MB per "active" user. Active users are defined as users who simultaneously access or query the database. For example, 30 users may be connected to Sybase IQ, but only 10 or so may be actively using a database at any one time.

### Memory requirements for loads

Sybase IQ also requires a portion of memory separate from the buffer caches to perform load operations, synchronization, and deletions. This memory is used for buffering I/O for flat files. Sybase IQ uses memory to buffer a read from disk. The size of this read equals the BLOCK FACTOR multiplied by the size of the input record. BLOCK FACTOR is an option of the LOAD TABLE command. With the default value of 10,000, an input row of data of 200 bytes results in 2MB total that Sybase IQ uses for buffering I/O. Memory requirements for a load are determined by the number and width of columns, not the number of rows.

This memory is required only when loading from flat files, using INSERT..LOCATION, or INSERT..SELECT.. A relatively small amount of memory is needed for deletions and updates.

#### Memory for thread stacks

Processing threads require a small amount of memory. The more IQ processing threads you use, the more memory needed. The -iqmt server switch controls the number of threads for IQ.

If you have a large number of users, the memory needed for Catalog Store processing threads also increases, although it is still relatively small. The -gn switch controls Catalog Store processing threads.

The total number of threads (-iqmt plus -gn) must not exceed the number allowed for your platform.

#### Other memory use

All commands and transactions use some memory. The following operations are the most significant memory users in addition to those discussed previously:

Backup. The amount of virtual memory used for backup is a function of
the IQ PAGE SIZE specified when the database was created. It is
approximately 2 \* number of CPUs \* 20 \* (IQ PAGE SIZE/16). On some
platforms you may be able to improve backup performance by adjusting
BLOCK FACTOR in the BACKUP command, but increasing BLOCK
FACTOR also increases the amount of memory used. See "Increasing
memory used during backup" in Chapter 13, "Backup and Data
Recovery," in Adaptive Server IQ System Administration Guide.

- Database validation and repair. When you check an entire database, the sp\_iqcheckdb procedure opens all IQ tables, their respective fields, and indexes before initiating any processing. Depending on the number of IQ tables and the cumulative number of columns and indexes in those tables, sp\_iqcheckdb may require very little or a large amount of virtual memory. To limit the amount of memory needed, use the sp\_iqcheckdb options to check or repair a single index or table.
- Dropping leaked blocks. The drop leaks operation also needs to open all IQ tables, files, and indexes, so it uses as much virtual memory as sp\_iqcheckdb uses when checking an entire database. It uses the IQ temp buffer cache to keep track of blocks used.

### Sybase IQ main and temp buffer caches

After determining how much overhead memory Sybase IQ needs, you must decide how to split what is left between your main IQ and temp buffer caches. The dashed line dividing the two areas in Figure 4-1 indicates that this split may change from one database to another based on several factors.

The general rule of thumb for IQ, unlike most other databases, is a split of about 40% for the main buffer cache and 60% for temp buffer cache. However, this rule of thumb is only a beginning. While some operations, such as queries with large sort-merge joins or inserts involving HG indexes, may require a larger temp buffer cache than main, other applications can have entirely different needs. IQ supports memory allocation ratios from 30/70 to 70/30, main to temp.

**Note** These guidelines assume you have one active database on your system at a time (that is, any Sybase IQ users are accessing only one database). If you have more than one active database, you need to further split the remaining memory among the databases you expect to use.

Sybase strongly recommends that you start with the general guidelines presented here and watch the performance of Sybase IQ by using its monitor tool (described in "Monitoring the buffer caches" on page 562) and any specific tools described in the *Sybase IQ Installation and Configuration Guide* for your platform.

### Buffer caches and physical memory

The total memory used for IQ main and temporary buffer caches, plus IQ memory overhead, and memory used for the operating system and other applications, must not exceed the physical memory on your system.

If you set buffer cache sizes higher than your system will accommodate, Sybase IQ cannot open the database. Specify the server startup options -iqmc (main cache size) and -iqtc (temp cache size) to open the database and reset the cache sizes from their default values, which are only 16MB for the main cache and 12MB for the temporary cache.

**Note** On some UNIX platforms, you may need to set other server switches to make more memory available for buffer caches. See "Platform-specific memory options" on page 57 for more information.

#### Other considerations

Sybase IQ buffer cache sizes may differ from one database to the next based on how you use it. For maximum performance, you need to change the settings between inserting, querying the database, and mixed use. In a mixed-use environment, however, it is not always feasible to require all users to exit the database so that you can reset buffer cache options. In those cases, you may need to favor either load or query performance. When possible, define the cache sizes before doing any work in the database.

The buffer cache and memory overhead guidelines also may differ between platforms. See your *Sybase IQ Installation and Configuration Guide* for any other issues.

## Example of setting buffer cache sizes

The following table lists factors that may consume memory for your system and shows an example of how much remains for your main and temp buffer caches. This example assumes that the system has 1GB of physical memory, no other significant applications on the hardware other than running Sybase IQ, and only one active database at a time. The table gives separate figures for the primary type of database access: queries or inserts.

Table 4-1: Example of memory (in MB) available for buffer caches

Memory use	Amount used	Memory available: Queries	Memory available: Inserts
Total amount of physical memory available (approximate in MB)		1000	1000
Operating system use assuming a minimum amount for a UNIX system	100 <sup>a</sup>	900	900
Overhead for number of active users: approximately 30 connected users but only about 10 active at 10MB each	100	825	
Overhead for inserts from flat files assuming a 200-byte record size and default settings	97		828
Memory remaining for the main and temp buffer caches		675	828
iqmc (Main_Cache_Memory_MB) setting: 60% of memory remaining for buffer caches		405	497
iqtc (Temp_Cache_Memory_MB) setting: 40% of memory remaining for buffer caches		270	331

<sup>&</sup>lt;sup>a</sup>Minimum operating system use for Windows is 30MB

As shown in the table, you should have one set of values for your buffer caches when primarily inserting into the database, another set when primarily querying the database, each differing from a typical mixed load of inserting and querying. To change the cache sizes, see "Setting buffer cache sizes." Remember that the cache size options do not take effect until you stop and restart the database.

## Setting buffer cache sizes

By default, Sybase IQ sets the size of the main and temporary buffer caches to 16MB and 12MB respectively. Most applications will require much higher values (limited by the total amount of physical memory). See the preceding sections to determine the right settings for your system.

Once you know what settings you need, use the options described in Table 12-2 to set buffer cache sizes. You may also use the options described in Table 12-3 to make more memory available for buffer caches.

Table 4-2: Settings that change buffer cache sizes

Method	When to use it	How long the setting is effective	For more information, see
-iqmc and -iqtc server switches	Recommended method. Sets cache sizes when the database and server are not running. Allows cache sizes >4GB.	From the time the server is started until it is stopped	"Setting buffer cache size server switches" on page 521
	Especially useful for 64- bit platforms, or if cache size database options are set larger than your system can accommodate.		
MAIN_CACHE_MEMORY_ MB and TEMP_CACHE_MEMORY_ MB database options	Set buffer cache sizes up to 4GB. Database must be open to set these values. This method is not recommended.	From the next time the database is restarted until you reset these options, or override them with server switches	"Database Options" chapter of Sybase IQ Reference Manual

Table 4-3: Settings that affect memory available for buffer caches

Method	When to use it	How long the setting is effective	For more information, see
-iqwmem server switch	Use on some UNIX platforms to provide additional memory for use as buffer caches. They do not actually set the cache sizes.	From the time the server is started until it is stopped	"Platform-specific memory options" on page 526
LOAD_MEMORY_MB database option	Indirectly affects buffer cache size, by controlling the memory that can be used for loads. On some platforms, allowing unlimited memory for loads means less memory is available for buffer caches.	Immediately until you reset the option	"Memory for loads, inserts, updates, synchronizations, and deletions" on page 44

## Setting buffer cache size server switches

Setting the buffer cache sizes using the server startup options -iqmc and -iqtc has two important advantages:

- It allows you to set cache sizes greater than 4GB. These larger cache sizes are not allowed on 32-bit platforms, but are recommended on 64-bit platforms.
- It allows you to modify cache sizes if you have set the database options larger than your system can accommodate, so that you cannot open the database.

Whether you use the database options or the server options, you must restart the server to change buffer cache sizes. The -iqmc and -iqtc server startup options only remain in effect while the server is running, so you need to include them every time you restart the server.

## Specifying page size

When you create a database, you set its page size. This parameter, in conjunction with the size of the buffer cache, determines memory use and disk I/O throughput for that database.

**Note** The page size cannot be changed and determines the upper size limit on some database objects.

## Setting the page size

Sybase IQ swaps data in and out of memory in units of **pages**. When you create a database, you specify a separate page size for the Catalog Store and the IQ Store. The Temporary Store has the same page size as the IQ Store.

For IQ page size recommendations for the best performance, see "Choosing an IQ page size" in Chapter 5, "Working with Database Objects,", *Adaptive Server IO System Administration Guide*.

Because the Catalog Store accounts for only a tiny fraction of I/O, the page size for the Catalog Store has no real impact on performance. The default value of 4096 bytes should be adequate.

The IQ page size determines two other performance factors, the default I/O transfer block size, and the maximum data compression for your database. These factors are discussed in the sections that follow.

### **Block size**

All I/O occurs in units of **blocks**. The size of these blocks is set when you create an IQ database; you cannot change it without recreating the database. By default, the IQ page size determines the I/O transfer block size. For example, the default IQ page size of 128KB results in a default block size of 8192 bytes. In general, IQ uses this ratio of default block size to page size, but it considers other factors also.

The default block size should result in an optimal balance of I/O transfer rate and disk space usage for most systems. It does favor saving space over performance, however. If the default block size does not work well for you, you can set it to any power of two between 4096 and 32,768, subject to the constraints that there can be no fewer than two and no more than 16 blocks in a page. You may want to set the block size explicitly in certain cases:

- For a raw disk installation that uses a disk array, larger blocks may give better performance at the expense of disk space.
- For a file system installation, to optimize performance over disk space, the IQ block size should be greater than or equal to the operating system's native block size, if there is one. You may get better I/O rates if your IQ block size matches your file system's block size.

Table 4-4 shows the default block size for each IQ page size.

Table 4-4: Default block sizes

IQ page size (KB)	Default block size (bytes)
64	4096
128 (default for new databases)	8192
256	16384
512	32768

## **Data compression**

Sybase IQ compresses all data when storing it on disk. Data compression both reduces disk space requirements and contributes to performance. The amount of compression is determined automatically, based on the IQ page size.

## Saving memory

If your machine does not have enough memory, to save memory you can try the following adjustments.

### Decrease buffer cache settings

You may be able to save memory by decreasing buffer cache sizes. Keep in mind that if you decrease the buffer caches too much, you could make your data loads or queries inefficient or incomplete due to insufficient buffers.

### Decrease memory used for loads

You can set the LOAD\_MEMORY\_MB option to limit the amount of heap memory used for loads and other similar operations. See ""Memory for loads, inserts, updates, synchronizations, and deletions" on page 44.

### Adjust blocking factor for loads

Use BLOCK FACTOR to reduce I/O when loading from a flat file. The BLOCK FACTOR option of the LOAD command specifies the blocking factor, or number of records per block, that were used when the input file was created. The default BLOCK FACTOR is 10.000.

The syntax for this load option is as follows:

```
BLOCK FACTOR = integer
```

Use the following guideline to determine BLOCK FACTOR:

```
record size * BLOCK FACTOR = memory required
```

You need extra memory for this option, in addition to the memory for the buffers. If you have a lot of memory available, or if no other users are active concurrently, increasing the value of BLOCK FACTOR can improve load performance.

## Optimizing for large numbers of users

Sybase IQ handles up to 200 user connections on 32-bit platforms (Linux and Windows 2000.2003/XP), and up to 1000 user connections on 64-bit platforms (Sun Solaris, HP-UX and Itanium, and AIX). To support this greater number of users on 64-bit systems, you may need to adjust both operating system parameters and start\_asiq server parameters. For recommendations, see the *Sybase IQ Installation and Configuration Guide* as well as the sections that follow.

### IQ command line option changes for large numbers of users

The following start\_asiq switches affect operations with large numbers of users:

-gm #\_connections\_to\_support

-iggovern # ACTIVE queries to support

-gn # Catalog Store front end threads

-c Catalog Store cache size

-ch size

-cl size

-gm This is the total number of connections the server will support. Statistically,

some of these are expected to be connected and idle while others are connected

and actively using the database.

Although 1000 users can be connected to IQ, for best throughput you should ensure that far fewer users are allowed to query at once, so that each of them has sufficient resources to be productive. The -iqgovern value places a ceiling on the maximum number of queries to execute at once. If more users than the -iqgovern limit have submitted queries, new queries will be queued until one of the active queries is finished.

The optimal value for -iqgovern depends on the nature of your queries, number of CPUs, and size of the IQ buffer cache. The default value is 2\*numCPU + 10. With a large number of connected users, you may find that setting this option to 2\*numCPU + 4 provides better throughput.

The correct value for -gn depends on the value of -gm. The start\_asiq utility calculates -gn and sets it appropriately. Setting -gn too low can prevent the server from operating correctly. Setting -gn above 480 is not recommended.

The Catalog Store buffer cache is also the general memory pool for the Catalog Store. To specify in MB, use the form -c nM, for example, -c 64M. Sybase recommends these values:

-iqgovern

-gn

-C

Table 4-5: Catalog buffer cache settings

For this many users	On these platforms	Set -c to this minimum value or higher
up to 1000	64-bit only	64MB
up to 200	64-bit	48MB (start_asiq default for 64-bit); larger numbers of users may benefit from 64MB
up to 200	32-bit	32MB (start_asiq default for 32-bit)

In some cases the standard Catalog cache size may be too small, for example, to accommodate certain queries that need a lot of parsing. In these cases, you may find it helpful to set -cl and -ch. For example, on 32-bit platforms, try these settings

-cl 128M

-ch 256M

Do not use -c in the same configuration file or command line with -ch or -cl. For related information, see the -ch cache-size option.

**Warning!** To control Catalog Store cache size explicitly, you must do *either* of the following, but not both, in your configuration file (*.cfg*) or on the UNIX command line for server startup:

- Set the -c parameter
- Set specific upper and lower limits for the Catalog Store cache size using the -ch and -cl parameters

Specifying different combinations of the parameters above can produce unexpected results.

-iqmt

You do not need to set the -iqmt option. If -iqmt is set too low for the number of specified connections, the number of threads will be increased to handle the number of requested connections. That is, -gm overrides -iqmt. However, if the number of IQ threads is elevated by means of the -iqmt option then that factor needs to be used in setting limits, as described in "Setting operating system parameters for large numbers of users."

## Increasing IQ Temp space for large numbers of users

You may need to increase your temp dbspace to accommodate more users.

### Relative priorities of new and existing connections

If Sybase IQ is very busy handling already connected users, it may be slow to respond to new connection requests. In extreme cases (such as test scripts that fire off hundreds of connections in a loop while the server is busy with inserts) new connections may have to wait up to a minute before becoming active or may even time out their connection request. In this situation, the server may appear to be down when it is merely very busy. A user getting this behavior should try to connect again.

### Setting operating system parameters for large numbers of users

To run Sybase IQ with many connections you may need to change certain system parameters. For details see the *Sybase IQ Installation and Configuration Guide*.

## Platform-specific memory options

On all platforms, Sybase IQ uses memory for four primary purposes:

- Main buffer cache
- Temporary buffer cache
- IQ memory overhead (including thread stacks)
- Load buffers

See Figure 4-1 on page 45 for a diagram of IQ memory use.

On all 64-bit platforms, the total amount of usable memory is effectively unlimited. The only limit is the system's virtual memory.

On 32-bit platforms restrictions apply; see the following table for details.

Table 4-6: Total available memory on 32-bit platforms

Platform	Total memory available
RedHat Linux 2.1	About 1.7GB available to IQ
RedHat Linux 3.0	About 2.7GB available to IQ
Windows 2000/2003/XP <sup>a</sup>	2.75GB available to IQ

<sup>a</sup>You need Windows 2000 Advanced Server or Datacenter Server, Windows Server 2003 Standard, Enterprise or Datacenter Edition, or Windows XP Professional to get this much memory, and you must set the /3GB switch. Without the switch, the limit is 2GB. This amount is the total memory available to the process. Total size of buffer caches must not exceed 2GB on Windows servers, even with the /3GB setting. For details, see the *Sybase IQ Installation and Configuration Guide for Windows*.

For more performance tuning hints on Windows platforms, see Chapter 6, "Tuning Servers on Windows Systems."

For UNIX systems only, Sybase IQ provides two command-line options that can help you manage memory.

Wired memory pool

On HP and Sun platforms, you can designate a specified amount of memory as "wired" memory. Wired memory is shared memory that is locked into physical memory. The kernel cannot page this memory out of physical memory.

Wired memory may improve IQ performance when other applications are running on the same machine at the same time. Dedicating wired memory to IQ, however, makes it unavailable to other applications on the machine.

To create a pool of "wired" memory on these UNIX platforms only, specify the -iqwmem command-line switch, indicating the number of MB of wired memory. (You must be user root to set -iqwmem, except on Sun.) On 64-bit platforms, the only upper limit on -iqwmem is the physical memory on the machine.

For example, on a machine with 14GB of memory, you may be able to set aside 10GB of wired memory. To do so, you specify:

-igwmem 10000

**Warning!** Use this switch only if you have enough memory to dedicate the amount you specify for this purpose. Otherwise, you can cause serious performance degradation.

#### **Note** For this version:

- On Sun Solaris, -iqwmem always provides wired memory.
- On HP, -iqwmem provides wired memory if you start the server as root. It
  provides unwired memory if you are not root when you start the server.
  This behavior may change in a future version.

Impact of other applications and databases

Remember, the memory used for the server comes out of a pool of memory used by all applications and databases. If you try to run multiple servers or multiple databases on the same machine at the same time, or if you have other applications running, you may need to reduce the amount of memory your server requests.

The server log reports how much memory you actually get:

Created 1073741824 byte segement id 51205 Attached at 80000000

Created 184549376 byte segement id 6151 Attached at C3576000

You can also issue the UNIX command ipcs -mb to see the actual number of segments.

Troubleshooting HP memory issues

If you have memory issues on HP-UX, check the value of the maxdsiz\_64bit kernel parameter. This parameter restricts the amount of virtual memory available to IQ on 64-bit HP processors. See your *Sybase IQ Installation and Configuration Guide* for the recommended value.

### Controlling file system buffering

On Solaris UFS and Windows file systems only, you can control whether file system buffering is turned on or off. Turning off file system buffering saves a data copy from the file system buffer cache to the main IQ buffer cache. Usually, doing so reduces paging, and therefore improves performance. Be aware of one exception: If the IQ page size for the database is less than the file system's block size (typically only in the case in testing situations) turning off file system buffering may *decrease* performance, especially during multiuser operation.

File system buffering is turned off by default for newly created IQ databases.

To disable file system buffering for existing databases, issue the following statement:

```
SET OPTION "PUBLIC".OS_FILE_CACHE_BUFFERING = OFF
```

You can only set this option for the PUBLIC group. You must shut down the database and restart it for the change to take effect.

**Note** Solaris does not have a kernel parameter to constrain the size of its file system buffer cache. Over time, the file system buffer cache grows and displaces the IQ buffer cache pages, leading to excess operating system paging activity and reduced IQ performance.

Windows can bias the paging algorithms to favor applications at the expense of the file system. This bias is recommended for IQ performance. See Chapter 6, "Tuning Servers on Windows Systems" for details.

### Other ways to get more memory

In certain environments, you may be able to adjust other options to make more memory available to Sybase IQ.

#### **Options for Java-enabled databases**

The JAVA\_HEAP\_SIZE option of the SET OPTION command sets the maximum size (in bytes) of that part of the memory that is allocated to Java applications on a per connection basis. Per connection memory allocations typically consist of the user's working set of allocated Java variables and Java application stack space. While a Java application is executing on a connection, the per connection allocations come out of the fixed cache of the database server, so it is important that a run-away Java application is prevented from using up too much memory.

The JAVA\_NAMESPACE\_SIZE option of the SET OPTION command sets the maximum size (in bytes) of that part of the memory that is allocated to Java applications on a per database basis. Per database memory allocations include Java class definitions. As class definitions are effectively read-only, they are shared among connections. Consequently, their allocations come right out of the fixed cache, and this option sets a limit on the size of these allocations.

# The process threading model

Sybase IQ uses operating system kernel threads for best performance. Threads can be found at the user level and at the kernel level. Lightweight processes are underlying threads of control that are supported by the kernel. The operating system decides which lightweight processes (LWPs) should run on which processor and when. It has no knowledge about what the user threads are, but does know if they are waiting or able to run.

The operating system kernel schedules LWPs onto CPU resources. It uses their scheduling classes and priorities. Each LWP is independently dispatched by the kernel, performs independent system calls, incurs independent page faults, and runs in parallel on a multiprocessor system.

A single, highly threaded process serves all Sybase IQ users. Sybase IQ assigns varying numbers of kernel threads to each user connection, based on the type of processing being done by that connection, the total number of threads available, and the various option settings.

#### Insufficient threads error

When you do not have enough server threads to initiate the query you have issued, you get the error:

Not enough server threads available for this query

This condition may well be temporary. When some other query finishes, threads are made available and the query may succeed the next time you issue it. If the condition persists, you may need to restart the server and specify more IQ threads, as described in the next section.

### IQ options for managing thread usage

Sybase IQ offers the following options to help you manage thread usage.

- To set the maximum number of threads available for Sybase IQ use, set the server startup option -iqmt. The default value is calculated from the number of connections and the number of CPUs and is usually adequate.
- To set the stack size of the internal execution threads in the server, set the server startup option -iqtss. The default value is generally sufficient, but may be increased if complex queries return an error indicating that the depth of the stack exceeded this limit.
- To set the maximum number of threads a single user will use, issue the command SET OPTION MAX\_IQ\_THREADS\_PER\_CONNECTION. This can be used to control the amount of resources a particular operation consumes. For example, the DBA can set this option before issuing an INSERT or LOAD command.

# Balancing I/O

This section explains the importance of balancing I/O on your system. It explains how to use disk striping and how to locate files on separate disks to gain better performance. Controlling the size of the message log file is also discussed.

### Raw I/O (on UNIX operating systems)

Most UNIX file systems divide disks into fixed size partitions. *Partitions* are physical subsets of the disk that are accessed separately by the operating system. Disk partitions are typically accessed in two modes: file system mode (through the UFS file system) or raw mode. Raw mode (sometimes called character mode) does unbuffered I/O, generally making a data transfer to or from the device with every read or write system call. The UFS mode is a UNIX file system and a buffered I/O system which collects data in a buffer until it can transfer an entire buffer at a time.

When you create a database or a dbspace, you can place it on either a raw device or a file system file. Sybase IQ determines automatically from the pathname you specify whether it is a raw partition or a file system file. Raw partitions can be any size.

For more information, see the section "Working with database objects" in Chapter 5, "Working with Database Objects" of the *Adaptive Server IQ System Administration Guide*.

### Using disk striping

Traditional file management systems allow you to locate individual files on specific disks. Consequently, all file operations occur against a single disk drive. Some operating systems allow you to create logical devices or volumes that span multiple disk drives. Once a file fills the first disk drive, it is automatically continued onto the next drive in the logical volume. This feature increases the maximum file size and concentrates activity on a single disk until it is full.

However, there is another way. *Disk striping* is a generic method of spreading data from a single file across multiple disk drives. This method allows successive disk blocks to be located on striped disk drives. Striping combines one or more physical disks (or disk partitions) into a single logical disk. Striped disks split I/O transfers across the component physical devices, performing them in parallel. They achieve significant performance gains over single disks.

Disk striping lets you locate blocks on different disks. The first block is located on the first drive. The second block is located on the second drive, and so on. When all the drives have been used, the process cycles back and uses additional blocks on the drives. The net effect of disk striping is the random distribution of data across multiple disk drives. Random operations against files stored on striped disks tend to keep all of the drives in the striped set equally busy, thereby maximizing the total number of disk operations per second. This is a very effective technique in a database environment.

You can use disk striping either as provided by your operating system and hardware, or IQ's internal disk striping.

### Setting up disk striping on UNIX

UNIX systems offering striped disks provide utilities for configuring physical disks into striped devices. See your UNIX system documentation for details.

### Setting up disk striping on Windows

On Windows systems, use hardware disk striping via an appropriate SCSI-2 disk controller. If your machine does not support hardware striping, but you have multiple disks available for your databases, you can use Windows striping to spread disk I/O across multiple disks. Set up Windows striping using the Disk Management.

### Recommendations for disk striping

Here are some general rules on disk striping:

- For maximum performance, the individual disks in a striped file system should be spread out across several disk controllers. But be careful not to saturate a disk controller with too many disks. Typically, most SCSI machines can handle 2–3 disks per controller. See your hardware documentation for more information.
- Do not put disks on the same controller as slower devices, such as tape drives or CD-ROMs. This slows down the disk controller.
- Allocate 4 disks per server CPU in the stripe.

- The individual disks must be identical devices. This means they must be
  the same size, have the same format, and often be the same brand. If the
  layouts are different, then the size of the smallest one is often used and
  other disk space is wasted. Also, the speed of the slowest disk is often
  used.
- In general, disks used for file striping should not be used for any other purpose. For example, do not use a file striped disk as a swap partition.
- Never use the disk containing the root file system as part of a striped device.

In general, you should use disk striping whenever possible.

**Note** For the best results when loading data, dump the data to a flat file located on a striped disk and then read the data into Sybase IQ with the LOAD TABLE command.

### Internal striping

Sybase IQ stores its information in a series of dbspaces—files or raw partitions of a device—in blocks. Assuming that disk striping is in use, Sybase IQ spreads data across all dbspaces that have space available. This approach lets you take advantage of multiple disk spindles at once, and provides the speed of parallel disk writes.

### **Disk striping option**

This section explains how you can use the option Sybase IQ provides to do disk striping, without using third party software. If you already have a disk striping solution through third party software and hardware, you should use that method instead.

Turning disk striping on or off

The syntax you use to turn disk striping on or off is:

#### SET OPTION "PUBLIC".DISK\_STRIPING = { ON | OFF }

The default for the DISK\_STRIPING option is ON for all platforms. When disk striping is ON, incoming data is spread across all dbspaces with space available. When disk striping is OFF, dbspaces (disk segments) are filled up from the front on the logical file, filling one disk segment at a time.

You must restart the IQ server in order for a change to the value of the DISK\_STRIPING option to take effect.

The database options MAIN\_DISK\_KB\_PER\_STRIPE and TEMP\_DISK\_KB\_PER\_STRIPE define the number of kilobytes (KB) to write to each dbspace before the disk striping algorithm moves to the next stripe for the IQ Main Store and the IQ Temporary Store, respectively. The default value for these options is 1, which rounds up to one page.

You can drop a dbspace using the DROP DBSPACE command when disk striping is on. Before dropping the dbspace, however, you must relocate all of the data in the dbspace using the sp\_iqrelocate stored procedure. Because disk striping spreads data across multiple dbspaces, the relocation process may require the relocation of many tables and indexes. Use the sp\_iqdbspaceinfo and sp\_iqdbspace stored procedures to determine which tables and indexes reside on a dbspace.

### Using multiple dbspaces

Using multiple dbspaces allows your IQ and temporary data to be broken down into multiple operating system files or partitions. These files can then be spread across multiple disks.

Like disk striping, randomness can be created by placing successive database files across multiple drives. You can create additional segments for your IQ and temporary data with the CREATE DBSPACE command.

When to create dbspaces

When possible, allocate all dbspaces when you create a database.

If you add dbspaces later, IQ stripes new data across both old and new dbspaces. Striping may even out, or it may remain unbalanced, depending on the type of updates you have. The number of pages that are "turned over" due to versioning has a major impact on whether striping is rebalanced.

### Strategic file locations

Performance related to randomly accessed files can be improved by increasing the number of disk drives devoted to those files, and therefore, the number of operations per second performed against those files. Random files include those for the IQ Store, the Temporary Store, the Catalog Store, programs (including the IQ executables, user and stored procedures, and applications), and operating system files.

Conversely, performance related to sequentially accessed files can be improved by locating these files on dedicated disk drives, thereby eliminating contention from other processes. Sequential files include the transaction log and message log files.

To avoid disk bottlenecks, follow these suggestions:

- Keep random disk I/O away from sequential disk I/O.
- Isolate IQ database I/O from I/O for proxy tables in other databases, such as Adaptive Server Enterprise.
- Place the transaction log and message log on separate disks from the IQ Store, Catalog Store, and Temporary Store, and from any proxy databases such Adaptive Server Enterprise.
- Place the database file, temporary dbspace, and transaction log file on the same physical machine as the database server.

#### The transaction log file

The transaction log file contains information that allows Sybase IQ to recover from a system failure. The default filename extension for this file is *.log*.

To move or rename the transaction log file, use the Transaction Log utility (dblog). For syntax and details, see Chapter 3, "Database Administration Utilities," *Sybase IQ Utility Guide*.

**Warning!** The Sybase IQ transaction log file is different than most relational database transaction log files. If for some reason you lose your database files, then you lose your database (unless it is the log file that is lost). However, if you have an appropriate backup, then you can reload the database.

Truncating the transaction log

Sybase IQ records in the transaction log the information necessary to recover from a system failure. Although the information logged is small for each committed transaction, the transaction log continues to grow is size. In systems with a high number of transactions that change data, over a period of time the log can grow to be very large.

Log truncation requires the IQ servers involved to be taken off line. When to truncate the log is really up to the DBA responsible for supporting the IQ systems, and depends on the growth profile of the log file and the operational procedures at the site. The log truncation procedure should be scheduled at least once a month or more frequently if the log file is exceeding 100MB.

There are two ways to truncate the transaction log:

- Using the -m database server switch, which causes the transaction log to be truncated after each checkpoint for all databases
- Using the DELETE\_OLD\_LOGS database option

There are important considerations to take into account when choosing which of these methods to use. IQ database replication inherently relies on transaction log information. For this reason, only the DELETE\_OLD\_LOGS option should be used for a multiplex database (see "Truncating the transaction log for a multiplex database."). Also, the transaction log provides Sybase support with valuable information for problem diagnosis and reproduction. Both methods should include archiving the existing log (keeping a copy of the log), in case Sybase support needs the log for further diagnostic work.

Truncating the transaction log for a non-multiplex database

Use the -m server startup switch to truncate the transaction log of a non-multiplex database. Note that leaving the -m server startup switch permanently set is *not* recommended. This switch should only be used to start IQ for a transaction log truncation. How this is done is up to the DBA, but the following procedure provides a suggestion.

#### **❖** To truncate the transaction log of a non-multiplex database:

- 1 Create a copy of the server switches .cfg file with a name identifying the file as the log truncation configuration setting and edit this copy of the file to add the -m switch.
- 2 Perform normal full backup procedures, including making copies of the .*db* and .*log* files.
- 3 Shutdown IQ. Verify that 'CloseDatabase' was written in the *iq.msg* file.
- 4 Restart IQ with the configuration file containing the –m option. Note that no user access or transactions should be allowed at this time.
- 5 Shut down IQ and restart using the configuration file without the –m option set.

Truncating the transaction log for a multiplex database

#### To truncate the transaction log of a multiplex database:

- Back up the database from the write server, if you have not already done
- 2 Set the DELETE\_OLD\_LOGS option on the write server:

SET OPTION Public.Delete\_Old\_Logs='On'

3 Stop the write server's dbremote and restart it with the -x command line switch. (Create a special version of the *start\_dbremote.bat* script, found in the write server's database directory, to do this.) This truncates the log at the write server. For example:

```
cd \Server01\mpxdb\
cmd /c start dbremote -k -q -v -o -x
"d:\Server01\mpxdb\dbremote.log" -c
"uid=DBA;pwd=SQL;eng=Server01;dbf=d:\Server01\mpxdb
\mpxdb;links=tcpip{port=1704;host=JANED-PC}"
```

4 Clear the DELETE\_OLD\_LOGS option on the write server:

```
SET OPTION Public.Delete_Old_Logs='Off'
```

**Note** The query server transaction log is always truncated during synchronization, no matter when the write server log was last truncated.

### The message log

A message log file exists for each database. The default name of this file is *dbname.iqmsg*, although you can specify a different name when you create the database. The message log file is actually created when the first user connects to a database.

By default, Sybase IQ logs all messages in the message log file, including error, status, and insert notification messages. You can turn off notification messages in the LOAD and INSERT statements.

At some sites the message log file tends to grow rapidly, due to the number of insertions, LOAD option and NOTIFY\_MODULUS database option settings, or certain other conditions. Sybase IQ lets you limit the size of this file by wrapping the message log.

When you enable message log wrapping, as soon as the file reaches the maximum size specified in the IQMSG\_LENGTH\_MB database option, new messages are written starting at the beginning of the file. Existing messages are overwritten, line-by-line.

When wrapping is enabled, the tag <next msg insertion place> tells you where new messages are being placed. Additional tags at the beginning and end of the file remind you that log wrapping is enabled, and that the last message in the file may not be the most recent one.

To enable message log wrapping and set the maximum log file size, see "IQMSG\_LENGTH\_MB option" in *Sybase IQ Reference Manual*.

### Working space for inserting, deleting, and synchronizing

When you insert or delete data, and when you synchronize join indexes, Sybase IQ needs some working space in the IQ Store. This space is reclaimed for other purposes when the transaction that needs it commits.

Ordinarily, as long as you maintain a reasonable percentage of free space in your IQ Store, you will have enough free space. However, for certain deletions, depending on the size of the data and its distribution among database pages, you may need a large amount of working space. In the case where you are deleting a major portion of your database, and the data is distributed sparsely across many pages, you could temporarily double the size of your database.

### Setting reserved space options

Two database options, MAIN\_RESERVED\_DBSPACE\_MB and TEMP\_RESERVED\_DBSPACE\_MB, control the amount of space Sybase IQ reserves for certain operations. For more information see "Reserving space to handle out-of-space conditions" in *Adaptive Server IQ System Administration Guide*.

# Options for tuning resource use

The number of concurrent users of an IQ database, the queries they run, and the processing threads and memory available to them, can have a dramatic impact on performance, memory use, and disk I/O. Sybase IQ provides several options for adjusting resource use to accommodate varying numbers of users and types of queries. These may be:

- SET OPTION command options that affect only the current database.
- Command-line options that affect an entire database server.
- Connection parameters that affect the current connection only.

For more information on all of these options, including parameters, when the options take effect, and whether you can set them for both a single connection and the PUBLIC group, see the *Sybase IQ Reference Manual*.

### **Restricting concurrent queries**

The -iqgovern command-line option lets you control the number of concurrent queries on a server. This is not the same as the number of connections, which is controlled by your license.

The -iqgovern switch optimizes paging of buffer data out to disk, so that memory is used most effectively. The default value of -iqgovern is (2 x the number of CPUs) + 4.

### Setting the number of CPUS available

The -iqnumbercpus switch on the Sybase IQ startup command lets you specify the number of CPUs available to IQ. This switch is recommended only:

- On machines with Intel<sup>®</sup> CPUs and hyperthreading enabled
- On machines where an operating system utility has been used to restrict Sybase IQ to a subset of the CPUs within the machine

For details, see "Setting the number of CPUs" in the *Adaptive Server IQ System Administration Guide*.

### Limiting a query's temporary dbspace use

The QUERY\_TEMP\_SPACE\_LIMIT option of the SET command lets you restrict the amount of temporary dbspace available to any one query. By default, a query can use 2000MB of temporary dbspace.

When you issue a query, Sybase IQ estimates the temporary space needed to resolve the query. If the total estimated temporary result space for sorts, hashes, and row stores exceeds the current QUERY\_TEMP\_SPACE\_LIMIT setting, the query is rejected, and you receive a message such as:

Query rejected because it exceeds total space resource limit

If this option is set to 0, there is no limit, and no queries are rejected based on their temporary space requirements.

### Limiting queries by rows returned

The QUERY\_ROWS\_RETURNED\_LIMIT option of the SET command tells the query optimizer to reject queries that might otherwise consume too many resources. If the query optimizer estimates that the result set from a query will exceed the value of this option, it rejects the query with the message:

```
Query rejected because it exceed resource: Query_Rows_Returned_Limit
```

If you use this option, set it so that it only rejects queries that consume vast resources.

### Forcing cursors to be non-scrolling

When you use scrolling cursors with no host variable declared, Sybase IQ creates a temporary store node where query results are buffered. This storage is separate from the Temporary Store buffer cache. If you are retrieving very large numbers (millions) of rows, this store node can require a lot of memory.

You can eliminate this temporary store node by forcing all cursors to be non-scrolling. To do so, set the FORCE\_NO\_SCROLL\_CURSORS option to ON. You may want to use this option to save on temporary storage requirements if you are retrieving very large numbers (millions) of rows. The option takes effect immediately for all new queries submitted.

If scrolling cursors are never used in your application, you should make this a permanent PUBLIC option. It will use less memory and make a big improvement in query performance.

# Limiting the number of cursors

The MAX\_CURSOR\_COUNT option specifies a resource governor to limit the maximum number of cursors that a connection can use at once. The default is 50. Setting this option to 0 allows an unlimited number of cursors.

### Limiting the number of statements

The MAX\_STATEMENT\_COUNT option specifies a resource governor to limit the maximum number of prepared statements that a connection can use at once.

### Prefetching cache pages

The SET option PREFETCH\_BUFFER\_LIMIT defines the number of cache pages available to Sybase IQ for use in prefetching (the read ahead of database pages). This option has a default value of 0. Do not set this option unless advised to do so by Sybase Technical Support. For more information, see "PREFETCH\_BUFFER\_LIMIT option" in the *Sybase IQ Reference Manual*.

The SET option BT\_PREFETCH\_MAX\_MISS controls the way IQ determines whether to continue prefetching pages for a given query. If queries using HG indexes run more slowly than expected, try gradually increasing the value of this option. For more information, see "BT\_PREFETCH\_MAX\_MISS option" in the *Sybase IQ Reference Manual*.

### Optimizing for typical usage

Sybase IQ tracks the number of open cursors and allocates memory accordingly. In certain circumstances, USER\_RESOURCE\_RESERVATION option can be set to adjust the minimum number of current cursors that IQ thinks is currently using the product and hence allocate memory from the temporary cache more sparingly.

This option should only be set after careful analysis shows it is actually required. Contact Sybase Technical Support with details if you need to set this option.

### Controlling the number of prefetched rows

Prefetching is used to improve performance on cursors that only fetch relative 1 or relative 0. Two connection parameters let you change cursor prefetch defaults. PrefetchRows (PROWS) sets the number of rows prefetched; PrefetchBuffer (PBUF) sets the memory available to this connection for storing prefetched rows. Increasing the number of rows you prefetch may improve performance under certain conditions:

- The application fetches many rows (several hundred or more) with very few absolute fetches.
- The application fetches rows at a high rate, and the client and server are on the same machine or connected by a fast network.
- Client/server communication is over a slow network, such as a dial-up link or wide area network.

# Other ways to improve resource use

This section describes several ways to adjust your system for maximum performance or better use of disk space.

### Managing disk space in multiplex databases

Sybase IQ cannot drop old versions of tables while any user on any server might be in a transaction that might need the old versions. Sybase IQ may therefore consume a very large amount of disk space when table updates and queries occur simultaneously in a multiplex database. The amount of space consumed depends on the nature of the data and indexes and the update rate.

You can free disk blocks by allowing the write server to drop obsolete versions no longer required by queries. All users on all servers should commit their current transactions periodically to allow recovery of old table versions. The servers may stay up and are fully available. The dbremote processes must all continue to run to forward the latest information about the use of table versions on each query server to the write server.

### Load balancing among query servers

You may be able to use the IQ Network Client to balance the query load among multiplex query servers. This method requires an intermediate system that is able to dispatch the client connection to a machine in a pool, depending on the workload of the machine.

To use this method, on the IQ client system you create a special ODBC DSN, with the IP address and port number of this intermediate load balancing system, a generic server name, and the VerifyServerName connection parameter set to NO. When an IQ client connects using this DSN, the load balancer establishes the connection to the machine it determines is least loaded.

For details on how to define an ODBC DSN for use in query server load balancing, see "VerifyServerName parameter [Verify]" in Chapter 4, "Connection and Communication Parameters" of the *Adaptive Server IQ System Administration Guide*.

### **Restricting database access**

For better query performance, set the database to read-only, if possible, or schedule significant updates for low usage hours. Sybase IQ allows multiple query users to read from a table while you are inserting or deleting from that table. However, performance can degrade during concurrent updates to the database.

### Disk caching

*Disk cache* is memory used by the operating system to store copies of disk blocks temporarily. All file system based disk reads and writes usually pass through a disk cache. From an application's standpoint, all reads and writes involving disk caches are equivalent to actual disk operations.

Operating systems use two different methods to allocate memory to disk cache: fixed and dynamic. A preset amount of memory is used in a fixed allocation; usually a 10–15 percent memory allocation is set aside. The operating system usually manages this workspace using a LRU (least recently used) algorithm. For a dynamic allocation, the operating system determines the disk cache allocation as it is running. The goal is to keep as much memory in active use as possible, balancing the demand for real memory against the need for data from disk.

# Indexing tips

The following sections give some tips for selecting and managing indexes. See Chapter 4, "Adaptive Server IQ Indexes" for more information on these topics.

### Choosing the right index type

It is important to choose the correct index type for your column data. Sybase IQ provides some indexes automatically—a default index on all columns that optimizes projections, and an HG index for UNIQUE and PRIMARY KEYS and FOREIGN KEYS. While these indexes are useful for some purposes, you need other indexes to process certain queries as quickly as possible. Sybase IQ chooses the best index type for you when there are multiple index types for a column.

Adaptive Server IQ's query optimizer features an index advisor that generates messages when the optimizer would benefit from an additional index on one or more columns in your query. To activate the index advisor, set the INDEX\_ADVISOR option ON. Messages print as part of a query plan or as a separate message in the IQ message log if query plans are not enabled. For details, see INDEX\_ADVISOR option in "Database Options," *Sybase IQ Reference Manual*.

You should create either an LF or HG index in addition to the default index on LF or HG on grouping columns referenced by the WHERE clause in a join query. Sybase IQ cannot guarantee that its query optimizer will produce the best execution plan if some columns referenced in the WHERE clause lack either an LF or HG index. Non-aggregated columns referenced in the HAVING clause should also have the LF or HG index in addition to the default index. For example:

```
SELECT c.name, SUM(1.price * (1 - 1.discount))
FROM customer c, orders o, lineitem 1
WHERE c.custkey = o.custkey
   AND o.orderkey = 1.orderkey
   AND o.orderdate >= "1994-01-01"
   AND o.orderdate < "1995-01-01"
GROUP by c.name
HAVING c.name NOT LIKE "I%"
   AND SUM(1.price * (1 - 1.discount)) > 0.50
ORDER BY 2 desc
```

In addition to the default index, all columns in this example beside l.price and l.discount should have an LF or HG index.

### Using join indexes

Users frequently need to see the data from more than one table at once. This data can be joined at query time, or in advance by creating a join index. Sometimes you can improve query performance by creating a join index for columns that are joined in a consistent way.

Because join indexes require substantial time and space to load, you should create them only for joins needed on a regular basis. Sybase IQ join indexes support one-to-many and one-to-one join relationships.

### Allowing enough disk space for deletions

When you delete data rows, Sybase IQ creates a version page for each database page that contains any of the data being deleted. The versions are retained until the delete transaction commits. For this reason, you may need to add disk space when you delete data. See "Overlapping versions and deletions" on page 394 for details.

# Managing database size and structure

This section offers ideas on improving your database design and managing your data.

### Managing the size of your database

The size of your database depends largely on the indexes you create, and the quantity of data you maintain. You achieve faster query processing by creating all of the indexes you need for the types of queries your users issue. However, if you find that some tables or indexes are not needed, you can drop them. By doing so, you free up disk space, increase the speed of loads and backups, and reduce the amount of archive storage you need for backups.

To control the quantity of data stored in a given table, consider how best to eliminate data rows you no longer need. If your IQ database contains data that originated in an Adaptive Server Anywhere database, you may be able to eradicate unneeded data by simply replaying Anywhere deletions; command syntax is compatible. You can do the same with data from an Adaptive Server Enterprise database, because Sybase IQ provides Transact-SQL compatibility.

### **Controlling index fragmentation**

Internal index fragmentation occurs when index pages are not being used to their maximum volume.

Row fragmentation can occur when rows are deleted. If you delete an entire page of rows, that page is freed, but if some rows on a page are unused, unused space remains on the disk.

DML operations (INSERT, UPDATE, DELETE) that act on tables cause index fragmentation. Two stored procedures report fragmentation:

- sp\_iqrowdensity reports row fragmentation at the default index level. See "sp\_iqrowdensity procedure."
- sp\_iqindexfragmentation reports internal fragmentation within supplemental indexes. See "sp\_iqindexfragmentation procedure."

The database administrator may create other indexes to supplement the default index on a column. These indexes can use more space than needed when rows are deleted from a table.

Neither procedure recommends further action. The database administrator must examine the information reported and determine whether to take further action, such as recreating, reorganizing, or rebuilding indexes.

### Minimizing catalog file growth

Growth of the catalog files is normal and varies depending on the application and catalog content. The size of the .DB file does not affect performance, and free pages within the .DB file are reused as needed. To minimize catalog file growth:

- Avoid using IN SYSTEM on CREATE TABLE statements.
- Issue COMMIT statements after running system stored procedures.

Issue COMMIT statements during long-running transactions.

### **Denormalizing for performance**

Once you have created your database in normalized form, you may perform benchmarks and decide to intentionally back away from normalization to improve performance. Denormalizing:

- Can be done with tables or columns
- Assumes prior normalization
- Requires a knowledge of how the data is being used

Good reasons to denormalize are:

- All queries require access to the "full" set of joined data
- Computational complexity of derived columns require storage for selects

#### Denormalization has risks

Denormalization can be successfully performed only with thorough knowledge of the application and should be performed only if performance issues indicate that it is needed. One of the things to consider when you denormalize is the amount of effort it will then take to keep your data up-to-date with changes.

This is a good example of the differences between decision support applications, which frequently need summaries of large amounts of data, and transaction processing needs, which perform discrete data modifications. Denormalization usually favors some processing, at a cost to others.

Whatever form of denormalization you choose, it has the potential for data integrity problems which must be carefully documented and addressed in application design.

### Disadvantages of denormalization

Denormalization has these disadvantages:

 Denormalization usually speeds retrieval but can slow updates. This is not a real concern in a DSS environment.

- Denormalization is always application-specific and needs to be reevaluated if the application changes.
- Denormalization can increase the size of tables. This is not a problem in Sybase IQ, because you can optimize the storage of column data. For details, see the IQ UNIQUE column constraint in CREATE TABLE statement and "MINIMIZE\_STORAGE option" in Sybase IQ Reference Manual.
- In some instances, denormalization simplifies coding; in others, it makes it more complex.

#### Performance benefits of denormalization

Denormalization can improve performance by:

- Minimizing the need for joins
- Precomputing aggregate values, that is, computing them at data modification time, rather than at select time
- Reducing the number of tables, in some cases

### **Deciding to denormalize**

When deciding whether to denormalize, you need to analyze the data access requirements of the applications in your environment and their actual performance characteristics. Some of the issues to examine when considering denormalization include:

- What are the critical queries, and what is the expected response time?
- What tables or columns do they use? How many rows per access?
- What is the usual sort order?
- What are concurrency expectations?
- How big are the most frequently accessed tables?
- Do any processes compute summaries?
- Should you create join indexes to gain performance?

# Using UNION ALL views for faster loads

To minimize load times for very large tables, you can use a UNION ALL view. Sybase IQ lets you partition tables by splitting the data into several separate base tables (for example, by date). You load data into these smaller tables. You then join the tables back together into a logical whole by means of a UNION ALL view, which you can then query.

UNION ALL views are simple to administer. If the data is partitioned by month, for example, you can drop an entire month's worth of data by deleting a table and updating the UNION ALL view definition appropriately. You can have many view definitions for a year, a quarter, and so on, without adding extra date range predicates.

To create a UNION ALL view, choose a logical means of dividing a base table into separate physical tables. The most common division is by month.

For example, to create a view including all months for the first quarter, enter:

CREATE VIEW
SELECT \* JANUARY
UNION ALL
SELECT \* FEBRUARY
UNION ALL
SELECT \* MARCH
UNION ALL

Each month, you can load data into a single base table—JANUARY, FEBRUARY, or MARCH in this example. Next month, load data into a new table with the same columns, and the same index types.

For syntax details, see UNION operation in the Sybase IQ Reference Manual.

Note You cannot perform an INSERT...SELECT into a UNION ALL view.

### Optimizing queries that reference UNION ALL views

All partitions in a UNION ALL view must have a complete set of indexes defined for optimization to work.

Queries with DISTINCT will tend to run more slowly using a UNION ALL view than a base table.

Sybase IQ includes patented optimizations for UNION ALL views, including:

- Split group by over union all view
- Pushdown join into union all view

Should you need to adjust performance for queries that reference UNION ALL views, you may want to set the Join\_Preference database option, which affects joins between UNION ALL views. For details of these options, see Chapter 5, "Database Options" in the *Sybase IQ Reference Manual*.

# **Network performance**

The following sections offer suggestions for solving some network performance issues.

### Improving large data transfers

Large data transfers simultaneously decrease overall throughput and increase the average response time. Here are some suggestions to improve performance during these transfers:

- Perform large transfers during off-hour periods, if possible.
- Limit the number of concurrent queries during large transfers.
- Do not run queries and insertions concurrently during large transfers.
- Use stored procedures to reduce total traffic.
- Use row buffering to move large batches through the network.
- If large transfers are common, consider installing better network hardware that is suitable for such transfers. For example:
  - Token ring—responds better during heavy utilization periods than ethernet hardware.
  - Fiber optic—provides very high bandwidth, but is usually too expensive to use throughout the entire network.
  - Separate network—can be used to handle network traffic between the highest volume workstations and the server.

### Isolate heavy network users

In case A in Figure 12-4, clients accessing two different database servers use one network card. That means that clients accessing Servers A and B have to compete over the network and past the network card. In the case B, clients accessing Server A use a different network card than clients accessing Server B.

It would be even better to put your database servers on different machines. You may also want to put heavy users of different databases on different machines.

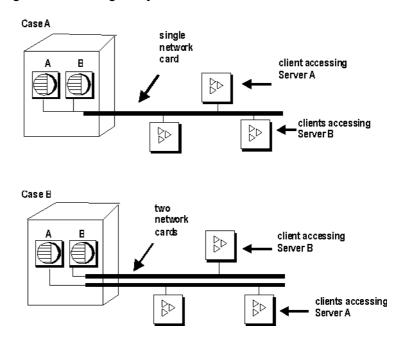

Figure 4-2: Isolating heavy network users

### Put small amounts of data in small packets

If you send small amounts of data over the network, keep the default network packet size small (default is 512 bytes). The -p server startup option lets you specify a maximum packet size. Your client application may also let you set the packet size.

### Put large amounts of data in large packets

If most of your applications send and receive large amounts of data, increase default network packet size. This will result in fewer (but larger) transfers.

### Process at the server level

Filter as much data as possible at the server level.

# CHAPTER 5 Monitoring and Tuning Performance

About this chapter

This chapter describes tools you use to monitor Sybase IQ performance. Use these tools to determine whether your system is making optimal use of available resources. To understand how Sybase IQ uses memory, process threads, and disk, and to learn about options you can set to control resource use, see Chapter 4, "Managing System Resources." See also the sections on performance implications and tuning in other chapters of this guide for more tuning hints.

# Viewing the Sybase IQ environment

The first step in tuning Sybase IQ performance is to look at your environment. You have various options:

- Use system monitoring tools (each system and site has different tools in place).
- Use one of the stored procedures that displays information about Sybase IQ. See the next section for more information.
- Determine appropriateness of index types. See Chapter 6, "Using Sybase IQ Indexes" in *Adaptive Server IQ System Administration Guide* for more information about choosing index types.
- For on-screen information, look at your insert and delete notification messages. Chapter 7, "Moving Data In and Out of Databases" in Adaptive Server IQ System Administration Guide gives more information about these messages.
- Look at the IQ message file, called dbname.iqmsg by default.
- Use the performance monitor in Sybase Central.

### **Getting information using stored procedures**

Sybase IQ offers several stored procedures that display information about your database:

- sp\_iqconnection displays statistics about user connections and versions
- sp\_iqcontext displays information about what statements are executing
- sp\_iqcheckdb checks the validity of your current database
- sp\_iqdbstatistics reports results of the most recent sp\_iqcheckdb
- sp\_iqdbsize gives the size of the current database
- sp\_iqspaceinfo displays space usage by each object in the database
- sp\_iqstatus displays miscellaneous status information about the database.
- sp\_iqtablesize gives the size of the table you specify.
- sp\_iqgroupsize lists the members of the specified group.

See *Sybase IQ Reference Manual* for syntax details and examples of all Sybase IQ stored procedures.

### **Using the Sybase Central performance monitor**

You can monitor server statistics using Sybase Central as follows.

#### Monitoring performance in Sybase Central

- Select a server.
- 2 On the Statistics tab, right-click the name on the and choose Add to Performance Monitor.
- 3 Click the Performance Monitor tab. Sybase Central only tracks the difference from one snapshot to the next, so some selected statistics may show no activity in the Performance Monitor.

For a description of each statistic, right-click its name on the Statistics tab, and choose Properties. You may also graph that statistic on the Performance Monitor by clicking the checkbox on the Properties tab, choosing Apply, and OK.

# Monitoring the buffer caches

Sybase IQ provides a tool to monitor the performance of the buffer caches. This monitor collects statistics on the buffer cache, memory, and I/O functions taking place within Sybase IQ, and stores them in a log file.

Buffer cache performance is a key factor in overall performance of Sybase IQ. Using the information the monitor provides, you can fine tune the amount of memory you allocate to the main and temp buffer caches. If one cache is performing significantly more I/O than the other, reallocate some of the memory appropriately. Reallocate in small amounts such as 10 to 50MB and on an iterative basis. After reallocating, rerun the workload and monitor the changes in performance.

### Starting the buffer cache monitor

You run the IQ buffer cache monitor from DBISQL. Each time you start the monitor it runs as a separate kernel thread within IQ.

Use this syntax to start the monitor:

IQ UTILITIES { MAIN | PRIVATE }
INTO dummy\_table\_name
START MONITOR 'monitor\_options [ ... ]'

MAIN starts monitoring of the main buffer cache, for all tables in the IQ Store of the database you are connected to.

PRIVATE starts monitoring of the temp buffer cache, for all tables in the Temporary Store of the database you are connected to.

You need to issue a separate command to monitor each buffer cache. You must keep each of these sessions open while the monitor collects results; a monitor run stops when you close its connection. A connection can run up to a maximum of two monitor runs, one for the main and one for the temp buffer cache.

*dummy\_table\_name* can be any IQ base or temporary table. The table name is required for syntactic compatibility with other IQ UTILITIES commands. It is best to have a table that you use only for monitoring.

To control the directory placement of monitor output files, set the MONITOR\_OUTPUT\_DIRECTORY option. If this option is not set, the monitor sends output to the same directory as the database. All monitor output files are used for the duration of the monitor runs. They remain after a monitor run has stopped.

Either declare a temporary table for use in monitoring, or create a permanent dummy table when you create a new database, before creating any multiplex reader nodes. These solutions avoid DDL changes, so that data stays up on reader nodes during production runs.

#### Tip

To simplify monitor use, create a stored procedure to declare the dummy table, specify its output location, and start the monitor.

'monitor\_options' can include one or more of the following values:

- -summary displays summary information for both the main and temp buffer caches. If you do not specify any monitor options, you receive a summary report. The fields displayed are as described for the other options, plus the following:
  - *Users*: Number of users connected to the buffer cache
  - *IO*: Combined physical reads and writes by the buffer cache
- -cache displays activity in detail for the main or temp buffer cache. Critical fields are Finds, HR%, and BWaits. The fields displayed are:
  - Finds: Find requests to the buffer cache
  - Creats: Requests to create a page within the database
  - *Dests*: Requests to destroy a page within the database
  - *Dirty*: Number of times the buffer was dirtied (modified)
  - HR%: Hit rate, the percentage of above satisfied by the buffer cache without requesting any I/O. The higher the Hit Rate the better, usually 90% 100% if you set the cache large enough. For a large query, Hit Rate may be low at first, but increase as prefetching starts to work.
  - *BWaits*: Find requests forced to wait for a busy page (page frame contention). Usually it is low, but is some special cases it may be high. For example, if identical queries are started at the same time, both need the same page, so the second request must wait for the first to get that page from disk.
  - *ReReads*: Approximate number of times the same portion of the store needed to be reread into the cache within the same transaction. Should always be low, but a high number is not important for Sybase IQ 12.4.2 and above.

- FMiss: False misses, number of times the buffer cache needed multiple lookups to find a page in memory. This number should be 0 or very small. If the value is high, it is likely that a rollback occurred, and certain operations needed to be repeated
- *Cloned*: Number of buffers that Sybase IQ needed to make a new version for a writer, while it had to retain the previous version for concurrent readers. A page only clones if other users are looking at that page.
- Reads/Writes: Physical reads and writes performed by the buffer cache
- *PF/PFRead*: Prefetch requests and reads done for prefetch.
- *GDirty*: Number of times the LRU buffer was grabbed dirty and Sybase IQ had to write it out before using it. This value should not be greater than 0 for a long period. If it is, you may need to increase the number of sweeper threads or move the wash marker.
- *Pin%*: Percentage of pages in the buffer cache in use and locked.
- *Dirty%*: Percentage of buffer blocks that were modified. Try not to let this value exceed 85-90%; otherwise, GDirty will become greater than 0.
- -cache\_by\_type produces the same results as -cache, but broken down by IQ page type. (An exception is the Bwaits column, which shows a total only.) This format is most useful when you need to supply information to Sybase Technical Support.
- -file\_suffix suffix creates a monitor output file named <dbname>.<connid>-<main\_or\_temp>-<suffix>. If you do not specify a suffix, it defaults to igmon.
- -io displays main or temp (private) buffer cache I/O rates and compression ratios during the specified interval. These counters represent all activity for the server; the information is not broken out by device. The fields displayed are:
  - *Reads*: Physical reads performed by the buffer cache
  - Lrd(KB): Logical kilobytes read in (page size multiplied by the number of requests)
  - *Prd(KB)*: Physical kilobytes read in
  - Rratio: Compression ratio of logical to physical data read in, a measure of the efficiency of the compression to disk for reads

- Writes: Physical writes performed by the buffer cache
- *Lwrt(KB)*: Logical kilobytes written
- *Pwrt(KB)*: Physical kilobytes written
- Wratio: Compression ratio of logical to physical data written
- -bufalloc displays information on the main or temp buffer allocator, which
  reserves space in the buffer cache for objects like sorts, hashes, and
  bitmaps.
  - *OU*: User\_Resource\_Reservation option setting (formerly Optimize\_For\_This\_Many\_Users)
  - AU: Current number of active users
  - *MaxBuf*: Number buffers under control of the buffer allocator
  - Avail: Number of currently available buffers for pin quota allocation
  - AvPF: Number of currently available buffers for prefetch quota allocation
  - *Slots*: Number of currently registered objects using buffer cache quota
  - *PinUser*: Number of objects (for example, hash, sort, and B-Tree objects) using pin quota
  - *PFUsr*: Number of objects using prefetch quota
  - *Posted*: Number of objects that are pre-planned users of quota
  - *UnPost*: Number of objects that are ad hoc quota users
  - Locks: Number of mutex locks taken on the buffer allocator
  - Waits: Number of times a thread had to wait for the lock
- -contention displays many key buffer cache and memory manager locks.
  These lock and mutex counters show the activity within the buffer cache
  and heap memory and how quickly these locks were resolved. Watch the
  timeout numbers. If system time exceeds 20%, it indicates a problem.

**Note** Due to operating system improvements, IQ no longer uses spin locks. As a result, the woTO, Loops, and TOs statistics are rarely used.

- *AU*: Current number of active users
- LRULks: Number times the LRU was locked (repeated for the temp cache)

- *woTO*: Number times lock was granted without timeout (repeated for the temp cache)
- Loops: Number times IQ retried before lock was granted (repeated for the temp cache)
- *TOs*: Number of times IQ timed out and had to wait for the lock (repeated for the temp cache)
- *BWaits*: Number of "Busy Waits" for a buffer in the cache (repeated for the temp cache)
- *IOLock*: Number of times IQ locked the compressed I/O pool (repeated for the temp cache); can be ignored
- *IOWait*: Number of times IQ had to wait for the lock on the compressed I/O pool (repeated for the temp cache); can be ignored
- *HTLock*: Number of times IQ locked the block maps hash table (repeated for the temp cache)
- HTWait: Number of times IQ had to wait for the block maps hash table (repeated for the temp cache); HTLock and HTWait indicate how many block maps you are using
- *FLLock*: Number of times IQ had to lock the free list (repeated for the temp cache)
- *FLWait*: Number of times IQ had to wait for the lock on the free list (repeated for the temp cache)
- *MemLks*: Number of times IQ took the memory manager (heap) lock
- MemWts: Number of times IQ had to wait for the memory manager lock
- -threads displays counter used by the processing thread manager. Values
  are server-wide (i.e., it does not matter whether you select this option for
  main or private). They represent new events since the last page of the
  report.
  - *cpus*: Number of CPUs IQ is using; this may be less than the number on the system
  - Limit: Maximum number of threads IQ can use
  - *NTeams*: Number of thread teams currently in use
  - *MaxTms*: Largest number of teams that has ever been in use
  - *NThrds*: Current number of existing threads

- Resrvd: Number of threads reserved for system (connection) use
- *Free*: Number of threads available for assignment. Monitor this value— if it is very low, it indicates thread starvation
- Locks: Number of locks taken on the thread manager
- Waits: Number of times IQ had to wait for the lock on the thread manager

Note When an object or query needs work, IQ allocates a group of processing threads called a thread team. Useful options in adjusting thread use include database options MAX\_IQ\_THREADS\_PER\_CONNECTION and MAX\_IQ\_THREADS\_PER\_TEAM, and the server option -iqmt which specifies the number of threads IQ can use.

- -interval specifies the reporting interval in seconds. The default is every 60 seconds. The minimum is every 2 seconds. You can usually get useful results by running the monitor at the default interval during a query or time of day with performance problems. A very short interval may not give meaningful results. The interval should be proportional to the job time; one minute is generally more than enough.
  - The first display shows counters from the start of the server. Subsequent displays show the difference from the previous display.
- -append | truncate Append to existing output file or truncate existing output file, respectively. Truncate is the default.
- -debug is used mainly to supply information to Sybase Technical Support. It displays all the information available to the performance monitor, whether or not there is a standard display mode that covers the same information. The top of the page is an array of statistics broken down by disk block type. This is followed by other buffer cache statistics, memory manager statistics, thread manager statistics, free list statistics, CPU utilization, and finally buffer allocator statistics. The buffer allocator statistics are then broken down by client type (hash, sort, and so on) and a histogram of the most recent buffer allocations is displayed. Note that memory allocations indicate how much is allocated since the last page of the report.

**Note** The interval, with two exceptions, applies to each line of output, not to each page. The exceptions are -cache\_by\_type and -debug, where a new page begins for each display.

### Checking results while the monitor runs

On UNIX systems, you can watch monitor output as queries are running.

For example, you could start the monitor using the following command:

```
iq utilities main into monitor_tab
start monitor "-cache -interval 2 -file_suffix iqmon"
```

This command sends output to an ASCII file with the name *dbname.conn#-[main/temp]-iqmon*. So, for the database asiqdemo, results would be sent to *asiqdemo.2-main-iqmon*.

To watch results, issue the following command at the system prompt:

```
$ tail -f asigdemo.2-main-igmon
```

### Stopping the buffer cache monitor

The command you use to stop a monitor run is similar to the one you use to start it, except that you do not need to specify any options. Use this syntax to stop the IQ buffer cache monitor:

```
IQ UTILITIES { MAIN | PRIVATE }
INTO dummy_table_name STOP MONITOR
```

**Note** In order for certain option settings to take effect you must restart the database. If the monitor is running you need to shut it down so that the database can be restarted.

### **Examining and saving monitor results**

The monitor stores results in an ordinary text file. This file defaults to:

- dbname.connection#-main-iqmon for main buffer cache results
- *dbname.connection#-temp-iqmon* for temp buffer cache results

The prefix *dbname.connection#* represents your database name and connection number. If you see more than one connection number and are uncertain which is yours, you can run the Catalog stored procedure sa\_conn\_info. This procedure displays the connection number, user ID, and other information for each active connection to the database.

You can use the -file\_suffix parameter on the IQ UTILITIES command to change the suffix *iqmon* to a suffix of your choice.

To see the results of a monitor run, use a text editor or any other method you would normally use to display or print a file.

When you run the monitor again from the same database and connection number, by default it overwrites the previous results. If you need to save the results of a monitor run, copy the file to another location before starting the monitor again from the same database or use the -append option.

### **Examples of monitor results**

1993 99.9

This section shows sample results using different monitor options.

The -summary option produces results like the following. Note that it shows both main and temp buffer cache statistics, no matter which you request in the IQ UTILITIES command:

3342 98.7

Sybase Adaptive Server IQ Performance Monitor

#### **Buffer cache structure**

Sybase IQ automatically calculates the number of cache partitions for the buffer cache according to the number of CPUs on your system. If load or query performance in a multi-CPU configuration is slower than expected, you may be able to improve it by changing the value of the CACHE\_PARTITIONS database option. For details, see CACHE\_PARTITIONS option in *Sybase IQ Reference Manual*.

As buffers approach the Least Recently Used (LRU) end of the cache, they pass a wash marker. IQ writes the oldest pages—those past the wash marker—out to disk so that the cache space they occupy can be reused. A team of IQ processing threads, called sweeper threads, sweeps (writes) out the oldest buffers.

When IQ needs to read a page of data into the cache, it grabs the LRU buffer. If the buffer is still "dirty" (modified) it must first be written to disk. The Gdirty column in the monitor -cache report shows the number of times the LRU buffer was grabbed dirty and Sybase IQ had to write it out before using it.

Usually IQ is able to keep the Gdirty value at 0. If this value is greater than 0 for more than brief periods, you may need to adjust one of the database options that control the number of sweeper threads and the wash marker. See "SWEEPER\_THREADS\_PERCENT option" or "WASH\_AREA\_BUFFERS\_PERCENT option" in Chapter 2, "Database Options," *Sybase IQ Reference Manual*.

# Avoiding buffer manager thrashing

Operating system paging affects queries that need buffers which exceed the free memory available. Some of this paging is necessary, especially as you allocate more and more physical memory to your buffer caches. However, if you overallocate the physical memory to your buffer caches, the operating system paging occurs much more frequently, and it can cause your entire system to thrash. The reverse is true as well: IQ thrashes if you do not allocate enough memory to your buffer caches.

Buffer manager thrashing occurs when the operating system chooses less optimum buffers to page out to disk, which forces the buffer manager to make extra reads from disk to bring those buffers back to memory. Since Sybase IQ knows which buffers are the best candidates to flush out to disk, you want to avoid this operating system interference by reducing the overall number of page outs.

When you set buffer sizes, keep in mind the following trade-off:

- If the IQ buffer cache is too large, the operating system is forced to page as Sybase IQ tries to use all of that memory.
- If the IQ buffer cache is too small, then Sybase IQ thrashes because it cannot fit enough of the query data into the cache.

If you are experiencing dramatic performance problems, you should monitor paging to determine if thrashing is a problem. If so, then reset your buffer sizes as described in "Managing buffer caches".

If you monitor paging and determine that thrashing is a problem, you can also limit the amount of thrashing during the execution of a statement which includes a query that involves hash algorithms. Adjusting the HASH\_THRASHING\_PERCENT database option controls the percentage of hard disk I/Os allowed before the statement is rolled back and an error is returned.

The default value of HASH\_THRASHING\_PERCENT is 10%. Increasing HASH\_THRASHING\_PERCENT permits more paging to disk before a rollback and decreasing HASH\_THRASHING\_PERCENT permits less paging before a rollback.

Queries involving hash algorithms that executed in earlier versions of IQ may now be rolled back when the default HASH\_THRASHING\_PERCENT limit is reached. IQ reports the error Hash insert thrashing detected or Hash find thrashing detected. Take one or more of the following actions to provide the query with the resources required for execution:

- Relax the paging restriction by increasing the value of HASH\_THRASHING\_PERCENT.
- Increase the size of the temporary cache (DBA only). Keep in mind that
  increasing the size of the temporary cache reduces the size of the main
  cache.
- Attempt to identify and alleviate why IQ is misestimating one or more
  hash sizes for this statement. For example, check that all columns that need
  an LF or HG index have one. Also consider if a multicolumn index is
  appropriate.
- Decrease the value of the database option HASH\_PINNABLE\_CACHE\_PERCENT.

For more information on these database options, see the sections "HASH\_THRASHING\_PERCENT option" and "HASH\_PINNABLE\_CACHE\_PERCENT option" in Chapter 2, "Database Options" of the *Sybase IO Reference Manual*.

To identify possible problems with a query, generate a query plan by running the query with the temporary database options QUERY\_PLAN = 'ON' and QUERY\_DETAIL = 'ON', then examine the estimates in the query plan. The generated query plan is in the message log file.

#### Monitoring paging on Windows systems

Windows provides the System Monitor to help you monitor paging. To access it, select the object Logical Disk, the instance of the disk containing the file *PAGEFILE.SYS*, and the counter Disk Transfers/Sec. This should be on a separate disk from your database files. You can also monitor the Object Memory and the counter Pages/Sec. However, this value is the sum of all memory faults which includes both soft and hard faults.

#### Monitoring paging on UNIX systems

UNIX provides a system command, vmstat, to help you monitor system activity such as paging. The abbreviated command syntax is:

vmstat

interval count

The *interval* is the time between rows of output, and *count* is the number times a row of output is displayed. For more information about vmstat (including its options and field descriptions), see your operating system's documentation. Here is an example:

#### > vmstat 2 3

pr	oc	S	memoi	page						disk				fa		срі	1			
r	b	W	swap	free	re	m£	рi	ро	fr	de	sr	s0	s1	sd	in	sy	CS	us	sy	id
0	0	0	3312376	31840	0	8	0	0	0	0	0	0	0	0	297	201	472	82	4	14
0	0	0	3312376	31484	2	3	0	0	0	0	0	0	0	0	260	169	597	80	3	17
0	0	0	3312368	31116	0	8	0	0	0	0	0	0	0	0	205	1202	396	67	4	29

The above output shows a steady Sybase IQ querying state where the physical memory of the machine has not been overallocated. Little to no system page faulting is occurring. These next set of examples show vmstat output that indicates a problem. (The output shown omits some of the above fields to fit better on the page.)

                                                                           89
 0 0 3328704 167224
                        0 2993
                                   6
                                      0
                                          0
                                             0
                                                 0
                                                              222
                                                                    4
```

The first line of the above output provides a summary of the system activity since the machine was started. The first three lines show that there is approximately 200MB of free physical memory and that the machine is idle. The fourth line corresponds to Sybase IQ starting up for the first time. Beginning at the eighth line, the amount of free memory starts to reduce rapidly. This corresponds to the Sybase IQ buffer caches being allocated and database pages being read in from disk (note that CPU usage has increased). At this time there is little user CPU time as no queries have begun.

pro	procs memory						pa	age				faults			cpu		
r	b	W	swap	free	re	mf	pi	po	fr	de	sr	in	sy	CS	us	sy	id
7	0	0	3247636	58920	0	1880	1664	0	0	0	0	1131	442	1668	80	18	3
18	0	0	3246568	43732	0	709	1696	0	0	0	0	1084	223	1308	90	10	1
12	0	0	3246604	37004	0	358	656	0	0	0	0	600	236	722	95	5	0
15	0	0	3246628	32156	0	356	1606	0	0	0	0	1141	226	1317	91	9	0
19	0	0	3246612	26748	0	273	1248	0	0	0	0	950	394	1180	92	7	0

The above output is from slightly later when the query is underway. This is evident from the user mode CPU level (*us* field). The buffer cache is not yet full as page-in faults (*pi* field or KB paged in) are still occurring and the amount of free memory is still going down.

pro	ocs	3	memoi	сy			page	9			faults					cpu		
r	b	W	swap	free	re	mf	pi	ро	fr	de	sr	in	sy	cs	us	sy	id	
21	0	0	3246608	22100	0	201	1600	0	0	0	0	1208	1257	1413	88	12	0	
18	0	0	3246608	17196	0	370	1520	0	464	0	139	988	209	1155	91	8	0	
11	0	0	3251116	16664	0	483	2064	138	2408	0	760	1315	218	1488	88	12	0	
30	0	0	3251112	15764	0	475	2480	310	4450	0	1432	1498	199	1717	87	13	0	

The above output is from even later. On the third line of the output it shows that the system has reached its threshold for the amount of free memory it can maintain. At this point, page-outs (*po* field or KB paged out) occur and the level of system mode CPU (*sy* field) increases accordingly. This situation results because physical memory is overallocated: the Sybase IQ buffer caches are too big for the machine. To resolve this problem, reduce the size of one or both of the buffer caches.

#### **Buffer cache monitor checklist**

The following table summarizes the most common items to look for in monitor results, and suggests actions you may need to take if behavior is outside the normal range. The Statistic column lists the name you see in the standard monitor reports; if this statistic appears differently in the debug report, the debug statistic is also listed.

Remember that for any monitor statistic, a temporary anomaly may occur while the system changes state, such as when a new query is starting.

Table 5-1: Buffer cache monitor checklist

Statistic	Normal behavior	Behavior that needs adjusting	Recommended action
HR% (Cache hit rate)	Above 90%. For individual internal data structures like garray, barray, bitmap (bm), hash object, sort object, variable-length btree (btreev), fixed-length btree (btreef), bit vector (bv), dbext, dbid, vdo, store, checkpoint block (ckpt), the hit rate should be above 90% while a query runs. It may be below 90% at first. Once prefetch starts working (PF or PrefetchReqs > 0), the hit rate should gradually grow to above 90%.	Hit rate below 90% after prefetch is working.  Note Some objects do not do prefetching, so their hit rate may be low normally.	Try rebalancing the cache sizes of main versus temp by adjusting -iqmc and -iqtc. Also try increasing the number of prefetch threads by adjusting PREFETCH_THREADS _PERCENT option.

Statistic	Normal behavior	Behavior that needs adjusting	Recommended action
Gdirty (Grabbed Dirty)	0 in a system with a modest cache size (< 10GB).	GDirty > 0  Note Sweeper threads are activated only when the number of dirty pages reaches a certain	Adjust SWEEPER_THREADS_ PERCENT option (default 10%) or WASH_AREA_
		percentage of the wash area. If GDirty/GrabbedDirty is above 0 and the I/O rate (Writes) is low, the system may simply be lightly loaded, and no action is necessary.	BUFFERS_PERCENT option (default 20%) to increase the size of the wash area.
BWaits (Buffer Busy Waits)	0	Persistently > 0, indicating that multiple jobs are colliding over the same buffers.	If the I/O rate (Writes) is high, Busy Waits may be caused by cache thrashing. Check Hit Rate in the cache report to see if you need to rebalance main versus temp cache.  If a batch job is starting a number of nearly identical queries at the same time, try staggering the start times.
LRU Waits (LRUNum TimeOuts percentage in debug report)	20% or less	> 20%, which indicates a serious contention problem.	Check the operating system patch level and other environment settings. This problem tends to be an O.S. issue.
IOWait (IONumWaits)	10% or lower	> 10%	Check for disk errors or I/O retries
FLWait (FLMutexWait	20% or lower	> 20%	Check the dbspace configuration:
s)			Is the database almost out of space?
			Is DISK_STRIPING ON?
			Does sp_iqcheckdb report fragmentation greater than 15%?

Statistic	Normal behavior	Behavior that needs adjusting	Recommended action
HTWait (BmapHTNu mWaits)	10% or lower	> 10%	Contact Sybase Technical Support.
MemWts (MemNtimes Waited)			
(PFMgrCond VarWaits)			
CPU time (CPU Sys Seconds, CPU Total Seconds, in debug report)	CPU Sys Seconds < 20%	CPU Sys Seconds > 20%  If CPU Total Seconds also reports LOW utilization, and there are enough jobs that the system is busy, the cache may be thrashing or parallelism may be lost.	Adjust -iqgovern to reduce allowed total number of concurrent queries.  Check Hit Rate and I/O Rates in the cache report for cache thrashing.  Also check if hash object is thrashing by looking at the hit rate of the has object in cache_by_type (or debug) report: is it <90% while the I/O rate (Writes) is high?  Check query plans for attempted parallelism.  Were enough threads available?  Does the system have a very large number of CPUs? Strategies such as multiplex configuration may be
InUse%	At or near 100% except during	Less than about 100%	necessary.  The buffer cache may be
(Buffers in use)	startup		too large.  Try rebalancing the cache sizes of main versus temp by adjusting -iqmc and -iqtc.

Statistic	Normal behavior	Behavior that needs adjusting	Recommended action
Pin% (Pinned buffers)	< 90%	> 90 to 95%, indicating system is dangerously close to an Out of Buffers condition, which would cause transactions to roll back	Try rebalancing the cache sizes of main versus temp.  If rebalancing buffer cache sizes is not possible, try reducing -iqgovern to limit the number of jobs running concurrently.
Free threads (ThrNumFree)	Free > Resrvd	If the number of free threads drops to the reserved count, the system may be thread starved.	Try one of the following: Increase the number of threads by setting -iqmt. Reduce thread-related options: MAX_IQ_THREADS_ PER_CONNECTION, MAX_IQ_THREADS_
			PER_TEAM, PARALLEL_GBH_ UNITS (for queries using Group By hash). Restrict query engine
			resource allocations by setting USER_RESOURCE_ RESERVATION.
			Limit the number of jobs by setting -iqgovern.
FlOutOfSpace (debug only)	0, indicating that the free list for this store is not full; unallocated pages are available	1, indicating that this store (main or temporary) is fully allocated	Add more dbspace to that store

# System utilities to monitor CPU use

Use these operating system utilities to monitor CPU usage while using Sybase IQ.

On UNIX systems use:

- ps command
- vmstat command (see example in the previous section)
- sar command (UNIX SystemV)

On Windows systems use:

- System Monitor
- · Task Manager

# CHAPTER 6 Tuning Servers on Windows Systems

About this chapter

This chapter provides performance and tuning guidelines specific to running Sybase IQ on Windows systems. Use this chapter in conjunction with Chapter 4, "Managing System Resources."

This chapter covers the following topics:

- General performance guidelines
- Monitoring performance
- Using the NTFS cache
- Tuning inserts and queries
- Tuning for queries
- Tuning backup operations

# General performance guidelines

The following are general guidelines that apply to both loading and querying data. The recommended minimum amount of memory (RAM) for running Sybase IQ under Windows is 512MB. While Sybase IQ will function correctly with smaller memory configurations, performance may be compromised.

### Maximizing throughput

If you are running on Windows, make sure the Network Services Server option "Maximize Throughput for Network Applications" is enabled. Enabling this option ensures that the NTFS cache does not steal memory from Sybase IQ and cause excessive page faulting, particularly in memory-constrained environments.

#### ❖ To enable Maximize Throughput for Network Applications:

- 1 From the Control Panel, double click on the Network Services Server icon.
- 2 Select the Services tab and double click on the Server network service.
- 3 Click on the option "Maximize Throughput for Network Applications".
- 4 Click OK twice and reboot the machine.

#### **Preventing memory overallocation**

Excessive system page faulting results from overallocating the physical memory (RAM) of the machine. Excessive page faults severely degrade the performance of Sybase IQ. By carefully allocating Sybase IQ buffers, monitoring the virtual address space of the Sybase IQ process(es), and monitoring available physical memory, you can prevent memory overallocation. This section offers guidelines for monitoring Sybase IQ use of your machine's physical memory.

#### Monitoring physical memory

The amount of physical memory available to applications (Sybase IQ) is displayed under Physical Memory (K). If the Available value is consistently below 5000 it is possible the physical memory for the machine is overallocated. This is because at the 5000(K) mark, Windows produces page faults in order to maintain a minimum of 5MB of free memory.

To monitor physical memory, from the Task Manager applet, select the Performance tab.

#### File systems

The Windows file system supports compression at the file, directory and volume level. *You should disable Windows file system compression for all disks and volumes on which you store* Sybase IQ *databases.* This is because Sybase IQ provides built-in compression. The file system compression will be unable to reduce the database size further, but may add CPU overhead when performing reads or writes.

# **Monitoring performance**

Your primary tool for monitoring performance of Sybase IQ is the IQ performance monitor, described in Chapter 5, "Monitoring and Tuning Performance." However, you can also use operating system monitoring tools.

Windows provides two tools for monitoring the performance of your system.

Windows Task Manager has two windows that provide an easy-to-read overview of current system performance. To start the Task Manager type CTRL-ALT-DEL and select the Task Manager button. By selecting the Processes tab you can see a list of all the currently running processes on the system. To customize the columns displayed, select View—Select Columns. The CPU Usage, Memory Usage and Virtual Memory Size columns help you identify CPU or memory bottlenecks. The Performance tab allows you to see various counts and a history of the machine performance.

The System Monitor provides a more detailed analysis of your machine's performance. It allows you to monitor individual counters to various system and application objects, including processors, processes, disks and the network.

#### Monitoring virtual address space and working set

The virtual address space of a process is the total size of the process. The working set of a process is the amount of physical memory currently allocated to the process. In most cases, in order to avoid excessive system page faulting the virtual address space for the Sybase IQ process(es) should be less than the physical memory of the machine.

#### To monitor virtual address space and working set:

- 1 Start the Performance Monitor.
- 2 Click on the + icon and select the Process object.
- 3 Select the first Sybase IQ instance.
- 4 Select the counters Virtual Bytes and Working Set.

#### Monitoring page faults

From the Windows Performance Monitor select the Sybase IQ process as described above. Select the counter Page Faults/sec. This counter includes both the "soft" and "hard" page faults. Hard page faults are the page faults resulting in disk I/O. Soft page faults in general are not a performance issue.

To determine the number of hard page faults, select the object LogicalDisk and the instance of where the file *pagefile.sys* is located (this should be on a separate volume from the Sybase IQ database). Select the counter Disk Transfers/sec. This value when compared with the Page Faults/sec value will give an indication of the percentage of page faults that are hard page faults. Ideally there should be little to no I/O activity to the page file. In small memory configurations, however, paging is likely to occur.

Sustained hard page fault rates above 20 per second indicate that the physical memory of the machine has been overallocated.

# Using the NTFS cache

With the Network Services Server option "Maximize Throughput for Network Applications" enabled, use of the NTFS and its associated cache can improve the performance of Sybase IQ for both inserts and queries. This is largely due to the NTFS being able to store significantly more data than the Sybase IQ buffer cache, with the same amount of physical memory, and the performance of the Intel Pentium to decompress Sybase IQ pages. As a result, when you use Sybase IQ on Windows platforms, you should reduce the size of the IQ buffer caches from their normal recommended settings.

The IQ main and temp buffer caches store Sybase IQ data (pages) in uncompressed form. As a result, an Sybase IQ buffer cache of 100MB can store 100MB worth of data. Conversely, the NTFS cache manages Sybase IQ data in its compressed form. Therefore, if the compression ratio were 2:1, 100MB of NTFS cache is potentially storing 200MB of Sybase IQ data. As a result, the NTFS cache is likely to sustain a higher cache hit rate which can lead to a reduction in I/O. The savings in I/O outweigh the computational overhead needed to decompress data as it moves from the NTFS cache to the Sybase IQ buffer caches.

# **Tuning inserts and queries**

This section provides additional guidelines for tuning inserts running on Windows platforms.

#### Characteristics of well-tuned insert operations

A well-tuned Sybase IQ insert operation exhibits certain characteristics. You can observe these characteristics from the Windows Task Manager and Windows Performance Monitor.

- For the most part, the insert operation is CPU-bound. All CPUs within the
  system should be running at close to 100%, with 95% or higher of the CPU
  being executed in user mode. You can see this easily by clicking on the
  Performance tab of the Windows Task Manager with the View-Show
  Kernel Times option set.
- Physical memory should not be overallocated and in particular, the virtual
  address space for the Sybase IQ process should be less than the physical
  memory (RAM) for the machine. On machines with large amounts of
  physical memory, that is, 512MB to 2GB, this will not be a problem. On
  machines with small amounts of memory, that is, 256MB or less, see the
  additional guidelines in the following section.
- Hard page faults (I/O to the volume containing *pagefile.sys*) should be low and ideally close to 0 (zero).
- I/O operations to the IQ Store should be steady and within the I/O capacity of the disk subsystem.

Sybase IQ uses the Windows CreateFile option (for both creating and opening a file) that specifies a file is to be read for sequential access. This option is used on the files specified in the LOAD TABLE command. As a result, load performance is improved through read ahead and reduced NTFS Cache memory utilization.

Load performance can be further improved, sometimes significantly, by setting the size of the main and temporary IQ buffer caches considerably smaller than the calculated recommended values in Sybase IQ Administration and Performance Guide. The reasons for this performance improvement are described in "Using the NTFS cache" on page 112. You can set the main and temporary Sybase IQ buffer caches as much as 50% smaller than the calculated recommended values.

#### **Tuning for queries**

Query performance can be improved, sometimes significantly, by setting the size of the main buffer cache smaller than the calculated recommended value in Sybase IQ Administration and Performance Guide. The reasons for this are described in "Using the NTFS cache" on page 112.

You may also improve performance by making the temp buffer cache smaller. Be careful in a multiuser environment, however, because reducing the size of the temp buffer cache impacts the various page pinning and sort algorithms which, in turn, may degrade performance.

# **Tuning backup operations**

Windows supports only fixed-length I/O devices. This means that each read or write to tape must be the same size as the one that preceded it and the one that follows. If any read/write operation exceeds the capacity of the hardware device, the operation fails. For backup and restore operations, this means that your backup (or restore) fails unless all of your writes (or reads) are the size the hardware is configured for.

The Sybase IQ defaults are designed to make your read and write operations as efficient as possible on each platform. However, if you override the default block size when you create an IQ database, you need to adjust the block factor when you back up that database.

For any backup or restore:

```
block size x block factor ≈ I/O size
```

To adjust the block factor on a Windows system, you must know the maximum physical block size that can be handled by your tape device. This information usually is not documented by the drive manufacturer. To determine the value, typically 64KB, you need to write a small applet using WIN32 API calls. You must then use the block size of the database and the BLOCK FACTOR option of the BACKUP command to optimize backup performance. For complete syntax and usage, see the *Sybase IQ Reference Manual*.

The closer to the maximum block size you can make each I/O operation, the better your backup performance will be. Use an integral BLOCK FACTOR that when multiplied by the block size yields as close to the drive's block size as possible.

Keep in mind that Sybase IQ adds some extra data to each block as it is written, for data integrity. So, if your database block size is 8192, and the maximum block size handled by the tape device is 128KB, you cannot use a block factor of 16, even though 8192 \* 16 = 128KB. You have to account for the extra data added on each I/O operation by Sybase IQ and use a BLOCK FACTOR of 15. Note that 15 is the default block factor on Windows for the default database block size and the default IQ page size of 128KB.
