Contents

PART I: Building OOMs	1
CHAPTER 1: Getting Started with Object-Oriented Modeling	3
Creating an OOM	5
OOM Properties	7
CHAPTER 2: Building Use Case Diagrams	9
Use Case Diagram Objects	9
Creating a Use Case Diagram	10
Use Cases (OOM)	10
Creating a Use Case	11
Use Case Properties	11
Use Case Property Sheet Specification Tab	12
Use Case Property Sheet Implementation Classes Tab	12
Use Case Property Sheet Related Diagrams Tab	13
Actors (OOM)	13
Creating an Actor	15
Actor Properties	15
Actor Property Sheet Implementation Classes Tab	16
Actor Property Sheet Related Diagrams Tab	18
Reusing Actors	18
Use Case Associations (OOM)	18
Creating a Use Case Association	19
Use Case Association Properties	19

CHAPTER 3: Building Structural Diagrams	21
Class Diagram Basics	21
Class Diagram Objects	22
Creating a Class Diagram	23
Composite Structure Diagram Basics	24
Composite Structure Diagram Objects	24
Creating a Composite Structure Diagram	26
Object Diagram Basics	26
Object Diagram Objects	27
Creating an Object Diagram	28
Package Diagram Basics	28
Package Diagram Objects	28
Creating a Package Diagram	29
Classes (OOM)	29
Creating a Class	30
Class Properties	30
Class Property Sheet Detail Tab	33
Class Property Sheet Generic Tab	33
Class Property Sheet Script Tab	34
Class Property Sheet Preview Tab	35
Creating Java BeanInfo Classes	37
Creating a Java BeanInfo Class from the Language Menu	39
Creating a Java BeanInfo Class from the Class Contextual Menu	39
Generic Types and Methods	40
Creating Generic Types	40
Creating Generic Methods	40
Creating a Specialized Classifier	41
Creating a Bound Classifier	42
Generic Type Example	42
Composite and Inner Classifiers	43
Creating Inner Classifiers	44

Creating a Composite Classifier Diagram	44
Attaching a Classifier to a Data Type or a Return Type	45
Attaching a Classifier	46
Viewing the Migrated Attributes of a Class	46
Packages (OOM)	48
OOM Package Properties	50
Previewing the Code of a Package in an OOM	51
Defining the Diagram Type of a New Package	51
Interfaces (OOM)	52
Creating an Interface	52
Interface Properties	53
Interface Property Sheet Generic Tab	54
Objects (OOM)	55
Creating an Object	56
Object Properties	57
Object Property Sheet Attribute Values Tab	57
Linking a Classifier to an Object	59
Parts (OOM)	60
Creating a Part	61
Part Properties	61
Ports (OOM)	62
Creating a Port	63
Port Properties	63
Redefining Parent Ports	65
Attributes (OOM)	65
Creating an Attribute	66
Attribute Properties	66
Attribute Property Sheet Detail Tab	68
Adding Getter and Setter Operations to a Classifier ...	69
Copying an Attribute to a Class, Interface, or Identifier	70
Overriding an Attribute in PowerBuilder	72
Adding an Inherited Attribute to a Class	72
Identifiers (OOM)	73

Creating an Identifier	73
Creating a primary identifier when you create the class attributes	74
Defining the Primary Identifier from the List of Identifiers	74
Identifier Properties	75
Adding Attributes to an Identifier	75
Operations (OOM)	76
Creating an Operation	76
Creating a User-Defined Operation	77
Creating a Standard Operation	77
Inheriting and Overriding Operations from Parent Classifiers	79
Creating an Implementation Operation	79
Copying an Operation to Another Class	80
Operation Properties	81
Operation Property Sheet Implementation Tab	83
Operation Property Sheet Parameters Tab	84
Operation Property Sheet Generic Tab	86
Associations (OOM)	86
Creating an Association	88
Associations Properties	88
Associations Property Sheet Detail Tab	89
Association Implementation	91
Understanding the Generated Code	93
Creating an Association Class	94
Migrating Association Roles in a Class Diagram	95
Migrating Navigable Roles	95
Rebuilding Data Type Links	96
Linking an Association to an Instance Link	96
Generalizations (OOM)	97
Creating a Generalization	98
Generalization Properties	99
Dependencies (OOM)	100

Creating a Dependency	102
Dependency Properties	102
Realizations (OOM)	103
Creating a Realization	104
Realization Properties	104
Require Links (OOM)	105
Creating a Require Link	105
Require Link Properties	105
Assembly Connectors (OOM)	106
Creating an Assembly Connector	107
Assembly Connector Properties	107
Delegation Connectors (OOM)	108
Creating a Delegation Connector	109
Delegation Connector Properties	109
Annotations (OOM)	109
Attaching an Annotation to a Model Object	110
Creating a New Annotation Type	111
Using the Annotation Editor	114
Instance Links (OOM)	114
Creating an Instance Link	117
Instance Link Properties	117
Domains (OOM)	118
Creating a Domain	119
Domain Properties	119
Domain Property Sheet Detail Tab	121
Domain Property Sheet Other Tabs	122
Updating Attributes Using a Domain in an OOM	122
Check Parameters (OOM)	122
Setting Standard Check Parameters for Objects in an OOM	123
Defining Additional Check Parameters for Objects in an OOM	123
 CHAPTER 4: Building Dynamic Diagrams	 125

Communication Diagram Basics	125
Communication Diagram Objects	127
Creating a Communication Diagram	127
Creating a Communication Diagram from a Sequence Diagram	127
Sequence Diagram Basics	128
Creating a Sequence Diagram	130
Creating a Sequence Diagram from a Communication Diagram	130
Sequence Diagram Objects	130
Activity Diagram Basics	131
Activity Diagram Objects	133
Creating an Activity Diagram	133
Statechart Diagram Basics	134
Defining a Default Classifier in the Statechart Diagram	135
Statechart Diagram Objects	136
Creating a Statechart Diagram	136
Interaction Overview Diagram Basics	137
Interaction Overview Diagram Objects	137
Creating an Interaction Overview Diagram	138
Messages (OOM)	138
Creating a Message	140
Message Properties	140
Message Property Sheet Detail Tab	141
Creating Create and Destroy Messages in a Sequence Diagram	143
Creating Create Messages	144
Creating Destroy Messages	144
Creating a Recursive Message in a Sequence Diagram	146
Creating a Recursive Message Without Activation	147
Creating a Recursive Message with Activation	147

Messages and Gates	147
Sequence Numbers	149
Moving Sequence Numbers	150
Inserting Sequence Numbers	151
Increasing Sequence Numbers in a Communication Diagram	151
Decreasing Sequence Numbers in a Communication Diagram	152
Activations (OOM)	152
Creating an Activation	152
Creating an Activation at Creation of the Message	152
Creating an Activation from a Diagram:	153
Attaching a Message to an Activation	153
Detaching a Message from an Activation	154
Overlapping Activations	154
Moving an Activation	154
Resizing an Activation	155
Interaction References and Interaction Activities (OOM)	155
Creating an Interaction Reference	156
Creating an Interaction Activity	156
Interaction Reference and Interaction Activity Properties	157
Manipulating Interaction References	157
Interaction Fragments (OOM)	158
Creating an Interaction Fragment	158
Interaction Fragment Properties	158
Interaction Fragment Property Sheet Sub- Regions Tab	159
Manipulating Interaction Fragments	160
Activities (OOM)	161
Creating an Activity	162
Activity Properties	162
Activity Property Sheet Action Tab	163

Activity Property Sheet Input Parameters and Output Parameters Tabs	164
Activity Property Sheet Sub-Activities Tab	164
Specifying Activity Parameters	164
Specifying Action Types	165
Example: Using the Call Action Type	166
Example: Reading and Writing Variables	169
Decomposed Activities and Sub-Activities	171
Converting an Activity Diagram to a Decomposed Activity	173
Organization Units (OOM)	174
Creating an Organization Unit	174
Creating Organization Units with the Swimlane Tool	174
Organization Unit Properties	175
Attaching Activities to Organization Units	176
Displaying a Committee Activity	176
Managing Swimlanes and Pools	177
Moving, Copying and Pasting Swimlanes	177
Grouping and Ungrouping Swimlanes	178
Creating Links Between Pools of Swimlanes ...	180
Changing the Orientation of Swimlanes	181
Resizing Swimlanes	182
Changing the Format of a Swimlane	182
Starts (OOM)	182
Creating a Start	183
Start Properties	183
Ends (OOM)	183
Creating an End	184
End Properties	184
Decisions (OOM)	185
Creating a Decision	186
Decision Properties	186
Synchronizations (OOM)	187
Creating a Synchronization	188

Synchronization Properties	189
Flows (OOM)	189
Creating a Flow	190
Flow Properties	190
Object Nodes (OOM)	192
Creating an Object Node	193
Object Node Properties	193
States (OOM)	194
Creating a State	195
State Properties	195
State Property Sheet Actions Tab	195
State Property Sheet Deferred Events Tab	196
State Property Sheet Sub-States Tab	196
Decomposed States and Sub-states	196
Converting a Statechart Diagram to a Decomposed State	198
Transitions (OOM)	199
Creating a Transition	199
Transition Properties	200
Transition Property Sheet Condition Tab	200
Transition Property Sheet Trigger Tab	201
Events (OOM)	201
Creating an Event	202
Event Properties	202
Event Property Sheet Dependencies Tab	203
Event Property Sheet Parameters Tab	203
Defining Event Arguments	204
Actions (OOM)	204
Creating an Action	205
Action Properties	205
Action Property Sheet Condition Tab	206
Junction Points (OOM)	207
Creating a Junction Point	207
Junction Point Properties	207

CHAPTER 5: Building Implementation Diagrams	209
Component Diagram Basics	209
Component Diagram Objects	210
Creating a Component Diagram	211
Deployment Diagram Basics	211
Deployment Diagram Objects	212
Creating a Deployment Diagram	212
Components (OOM)	212
Creating a Component	213
Using the Standard Component Wizard	214
Component Properties	214
Component Property Sheet Interfaces Tab	216
Component Property Sheet Classes Tab	218
Component Property Sheet Files Tab	219
Component Property Sheet Operations Tab	220
Creating a Class Diagram for a Component	221
Deploying a Component to a Node	221
Nodes (OOM)	222
Creating a Node	223
Node Properties	223
Node Property Sheet Component Instances Tab	224
Node Diagrams	224
Creating a Node Diagram	224
Opening a Node Diagram	225
Closing a Node Diagram	225
Component Instances (OOM)	225
Creating a Component Instance	226
Component Instance Properties	226
Files (OOM)	227
Creating a File Object	228
File Object Properties	228
Node Associations (OOM)	229

Creating a Node Association	229
Node Association Properties	230
CHAPTER 6: Working with Web Services	233
Defining Web Services Tools	234
Defining Web Services Targets	236
Defining Web Service Components	236
Web Service Component Properties	237
Web Service Tab of the Component	237
WSDL Tab of the Component	238
WSDL Schema Tab of the Component	238
Preview Tab of the Component	238
Extended Attributes Tab of the Component ...	239
Creating a Web Service with the Wizard	240
Creating a Web Service from the Component Diagram	242
Defining Data Types for WSDL	242
WSDL Data Type Mappings	242
Selecting WSDL Data Types	243
Declaring Data Types in the WSDL	243
Web Service Implementation Class	243
Detail Tab of the Class	243
Preview Tab of the Class	244
Managing Web Service Methods	244
Creating a Web Service Method	244
Web Service Method Properties	245
Implementing a Web Service Method in Java	246
Defining the Return Type of an Operation	246
Defining the Parameters of an Operation	247
Implementing the Operation	249
Implementing a Web Service Method in .NET	251
Defining Web Service Method Extended Attributes ...	251
Defining SOAP Data Types of the WSDL Schema	252
Defining Web Service Component Instances	253

Web Service Tab of the Component Instance	254
WSDL Tab of the Component Instance	255
Using Node Properties	255
Generating Web Services for Java	255
Generating JAXM Web Services	256
Generating JAX-RPC Web Services	257
Generating Stateless Session Bean Web Services	258
Generating AXIS RPC Web Services	259
Generating AXIS EJB Web Services	260
Generating Java Web Services (JWS)	261
Testing Web Services for Java	261
Generating Web Services for .NET	261
Defining Web Services Generation Options in .NET ...	262
Defining Web Service Generation Tasks in .NET	262
Generating Web Services in .NET	263
Generating a .NET Proxy Class for a Web Service	263
Define the WSDL Variable	263
Generate the Client Proxy Classes	263
Deploying Web Services in .NET	264
Testing Web Services for .NET	264
Generating Web Services for Sybase WorkSpace	265
Creating a Java or EJB Web Service for Sybase WorkSpace	265
Defining the Java Class Package	266
Generating the Java or EJB Web Service for Sybase WorkSpace	267
Understanding the .svc_java or .svc_ejb File	267
Importing WSDL Files	268
Browsing WSDL Files from UDDI	270

PART II: Working with OOMs273

**CHAPTER 7: Generating and Reverse Engineering OO
Source Files275**

Generating OO Source Files from an OOM	275
Generating Source Files	275
Working with Generation Targets	278
Defining the Source Code Package	278
Enabling Trace Mode in Preview Tabs	279
Reverse Engineering OO Source Files into an OOM	279
Reverse Engineering OO Files into a New OOM	280
Reverse Engineering Encoding Format	281
Reverse Engineering into an Existing OOM	282
Synchronizing a Model with Generated Files	282
CHAPTER 8: Generating Other Models from an OOM	
.....	285
Mapping OOM Objects to other Model Objects	286
Managing Object Persistence During OOM to CDM	
Generation	287
Defining Object Persistence in the OOM	287
Managing Complex Data Type Persistence	288
Managing Multiplicity for Complex Persistent Data	
Types	289
Managing Object Persistence During OOM to PDM	
Generation	292
Defining Object Persistence in the OOM	292
Managing Complex Data Type Persistence	294
Managing Multiplicity for Complex Persistent Data	
Types	297
CHAPTER 9: Customizing the OOM Environment	301
Working with Object Language	301
Previewing the Code of an OOM	302
Modifying the Code Using Preview	303
Changing the Object Language of an OOM	303
Setting OOM Model Options	305
Setting OOM Display Preferences	307

Extending Your Modeling Environment with Extended Model Definitions	310
Creating Links with Extended Dependencies	311
CHAPTER 10: Checking an OOM	313
Domain Checks	313
Data Source Checks	314
Package Checks	314
Actor/Use Case Checks	315
Class Checks	315
Identifier Checks	322
Interface Checks	322
Class/Interface Attribute Checks	324
Class/Interface Operation Checks	325
Realization Checks	327
Generalization Checks	327
Object Checks	328
Instance Link Checks	329
Message Checks	329
State Checks	329
State Action Checks	330
Event Checks	331
Junction Point Checks	331
Activity Checks	332
Decision Checks	332
Object Node Checks	333
Organization Unit Checks	333
Start/End Checks	334
Synchronization Checks	334
Transition and Flow Checks	335
Component Checks	335
Node Checks	336
Component Instance Checks	337
Interaction Reference Checks	337

Class Part Checks	338
Class/Component Port Checks	339
Class/component Assembly Connector Checks	339
Association Checks	340
Activity Input and Output Parameter Checks	340
CHAPTER 11: Importing a Rational Rose Model into an OOM	341
Importing Rational Rose General Objects	341
Importing Rational Rose Use Case Diagrams	342
Importing Rational Rose Class Diagrams	343
Importing Rational Rose Collaboration Diagrams	344
Importing Rational Rose Sequence Diagrams	345
Importing Rational Rose Statechart Diagrams	345
Importing Rational Rose Activity Diagrams	346
Importing Rational Rose Component Diagrams	347
Importing Rational Rose Deployment Diagrams	348
CHAPTER 12: Importing and Exporting an OOM in XMI Format	349
Importing XMI Files	349
Exporting XMI Files	349
PART III: OOM Target Reference	351
CHAPTER 13: Working with Java	353
Java Public Classes	353
Java Enumerated Types (Enums)	353
JavaDoc Comments	358
Defining Values for Javadoc Tags	361
Javadoc Comments Generation and Reverse Engineering	364
Java 5.0 Annotations	364

Java Strictfp Keyword	365
Enterprise Java Beans (EJBs) V2	365
Using EJB Types	367
EJB Properties	368
Creating an EJB with the Wizard	370
Defining Interfaces and Classes for EJBs	373
Defining an Interface or a Class for an EJB	375
Defining Operations for EJBs	375
Adding an Operation to the Bean Class	376
Adding an Operation to an EJB Interface	377
Understanding Operation Synchronization	378
Understanding EJB Support in an OOM	379
Understanding EJB Initialization	380
Understanding EJB Synchronization	380
Understanding EJB Code Generation	380
Previewing the EJB Deployment Descriptor	383
Generating EJBs	385
What Kind of Generation to Use?	386
Understanding EJB Source and Persistence	388
Generating EJB Source Code and the Deployment Descriptor	389
Generating JARs	390
Reverse Engineering EJB Components	391
Enterprise Java Beans (EJBs) V3	392
Creating an EJB 3.0 with the Enterprise JavaBean Wizard	392
EJB 3.0 BeanClass Properties	396
EJB 3.0 Component Properties	397
Adding Further Interfaces and Classes to the EJB	397
EJB 3.0 Operation Properties	398
Java Servlets	399
Servlet Page of the Component	399
Defining Servlet Classes	399
Creating a Servlet with the Wizard	400

Understanding Servlet Initialization and Synchronization	401
Generating Servlets	402
Generating Servlet Web Deployment Descriptor	405
Generating WARs	405
Reverse Engineering Servlets	406
Java Server Pages (JSPs)	408
JSP Page of the Component	408
Defining File Objects for JSPs	408
Creating a JSP with the Wizard	409
Creating a JSP with the Wizard	409
Generating JSPs	410
Generating JSP Web Deployment Descriptor	410
Reverse Engineering JSPs	414
Generating Java Code	415
Defining Java Environment Variables	416
Selecting Java Generation Options	416
Selecting Java Generation Tasks	418
Generating Java Files	420
Reverse Engineering Java Code	421
Reverse Engineer Java Options Tab	423
Reverse Engineering Java Code Comments	425
CHAPTER 14: Working with the Eclipse Modeling Framework (EMF)	427
EMF Objects	427
EPackages	427
EClasses, EEnums, and EDataTypes	427
EAnnotations	428
EAttributes and EEnumLiterals	428
EReferences	428
EOperations and EParameters	429
Generating EMF Files	429

Reverse Engineering EMF Files	430
CHAPTER 15: Working with IDL	431
IDL Objects	431
Generating for IDL	440
Reverse Engineering IDL Files	441
CHAPTER 16: Working with PowerBuilder	443
Full-featured Mapping	443
Application	443
Structure	444
Function	444
User Object	444
Proxy	444
Window	444
Minimal Mapping	445
Selecting a PowerBuilder Version	445
Selecting a PowerBuilder Version During Generation	446
Selecting a PowerBuilder Version During Reverse Engineering	447
Generating for PowerBuilder	448
Generated Objects	448
Operation Generated Header	448
Generating Events	449
Selecting PowerBuilder Generation Options	449
Generating Objects for PowerBuilder	450
Reverse Engineering PowerBuilder	451
Reverse Engineered Objects	451
Operation Reversed Header	452
Overriding Attributes	452
Selecting PowerBuilder Reverse Engineering Options	453

Defining PowerBuilder reverse engineering options	454
PowerBuilder Reverse Engineering Process	455
Reverse Engineering PowerBuilder Objects	456
Loading a PowerBuilder Library Model in the Workspace	457
CHAPTER 17: Working with VB .NET	459
What Is Automatically Generated	459
Supported VB .NET Objects	460
Inheritance & Implementation	460
Namespace	460
Project	460
Accessibility	461
Class	462
Structure	462
Interface	463
Nested Types	463
Module	463
Enumeration	463
Custom Attributes	464
Shadows	465
Variables	465
Property	466
Method	467
Constructor & Destructor	469
Delegate	469
Event	470
Event Handler	471
External Method	471
Generating for VB.NET	471
Defining VB .NET Environment Variables	471
Selecting VB .NET Generation Options	472
Selecting VB .NET Generation Tasks	472

Generating VB.NET Files	473
Reverse Engineering VB .NET	473
Selecting VB .NET Reverse Engineering Options	474
Defining VB .NET Reverse Engineering Options	475
VB .NET Reverse Engineering Preprocessing	475
VB .NET Supported Preprocessing Directives . . .	476
Defining a VB .NET Preprocessing Symbol	476
VB .NET Reverse Engineering with Preprocessing	477
Reverse Engineering VB .NET Files	478
Working with ASP.NET	479
ASP Tab of the Component	479
Defining File Objects for ASP.NET	480
Creating an ASP.NET with the Wizard	480
Generating ASP.NET	482
CHAPTER 18: Working with Visual Basic 2005	485
Custom Visual Basic 2005 Tools	485
Visual Basic 2005 Assemblies	485
Creating an Assembly	486
Converting a Single-assembly Model to a Multi- assembly Model	486
Assembly Properties	487
Assembly Property Sheet Application Tab	487
Assembly Property Sheet Assembly Tab	487
Visual Basic 2005 Compilation Units	488
Creating a Compilation Unit	488
Creating an Empty Compilation Unit from the Browser	488
Creating and Populating a Compilation Unit from the Property Sheet of a Type	488
Adding Types to Compilation Units	489

Adding a Type to a Compilation Unit from the Compilation Unit Property Sheet	489
Adding a Type to a Compilation Unit from the Type Property Sheet	490
Creating a Generation Folder Structure	490
Adding Compilation Units to Folders	490
Previewing the Code to Be Generated for a Compilation Unit	491
Visual Basic 2005 Namespaces	491
Visual Basic 2005 Classes	491
Visual Basic 2005 Class Properties	492
Partial Types	492
Specifying the Compilation Unit to Which an Inner Type Belongs:	493
Visual Basic 2005 Interfaces	493
Visual Basic 2005 Interface Properties	493
Visual Basic 2005 Structs	493
Creating a Struct	494
Struct Properties	494
Visual Basic 2005 Delegates	494
Creating a Delegate	495
Delegate Properties	496
Visual Basic 2005 Enums	496
Creating an Enum	497
Enum Properties	497
Visual Basic 2005 Fields, Events, and Properties	497
To Create a Field, Event, or Property:	497
Field, Event, and Property Properties	498
Working with Properties	498
Working with Events	499
Visual Basic 2005 Methods	500
Method Properties	500
Constructor & Destructor	502
Visual Basic 2005 Inheritance and Implementation	502
Visual Basic 2005 Custom Attributes	502

Generating Visual Basic 2005 Code	502
Visual Basic 2005 Generation Dialog Options Tab	504
Visual Basic 2005 Generation Dialog Tasks Tab	505
Defining Visual Basic 2005 Environment Variables	505
Reverse Engineering Visual Basic 2005 Code	505
Visual Basic Reverse Engineer Dialog Options Tab	506
Visual Basic Reverse Engineering Preprocessing	
Directives	507
Visual Basic Supported Preprocessing Directives	
.....	508
Defining a Visual Basic Preprocessing Symbol	
.....	508
CHAPTER 19: Working with C#	511
What Is Automatically Generated	511
Supported C# Objects	512
Inheritance & Implementation	512
Namespace	512
Project	512
Accessibility	513
Class	513
Struct	515
Enumeration	515
Interface	516
Nested Types	516
Custom Attributes	516
Fields	516
Property	517
Indexer	519
Method	520
Constructor & Destructor	522
Delegate	522
Event	523
Operator Method	523

Conversion Operator Method	523
Documentation Tags	524
Generating for C#	525
Defining C# Environment Variables	525
Selecting C# Generation Options	526
Selecting C# Generation Tasks	526
Generating C# Files	526
Reverse Engineering C#	527
Selecting C# Reverse Engineering Options	528
Defining C# Reverse Engineering Options	529
C# Reverse Engineering Preprocessing	529
C# Supported Preprocessing Directives	530
Defining a C# Preprocessing Symbol	530
C# Reverse Engineering with Preprocessing	531
Reverse Engineering C# Files	532
CHAPTER 20: Working with C# 2.0	535
Custom C# 2.0 Tools	535
C# 2.0 Assemblies	535
Creating an Assembly	536
Converting a Single-assembly Model to a Multi-assembly Model	536
Assembly Properties	536
Assembly Property Sheet Application Tab	537
Assembly Property Sheet Assembly Information Tab	537
C# 2.0 Compilation Units	538
Creating a Compilation Unit	538
Creating an Empty Compilation Unit from the Browser	538
Creating and Populating a Compilation Unit from the Property Sheet of a Type:	538
Adding Types to Compilation Units	539

Adding a Type to a Compilation Unit from the Compilation Unit Property Sheet	539
Adding a Type to a Compilation Unit from the Type Property Sheet	540
Creating a Generation Folder Structure	540
Adding Compilation Units to Folders	540
Previewing the Code to Be Generated for a Compilation Unit	541
C# 2.0 Namespaces	541

PART I

Building OOMs

The chapters in this part explain how to model your information systems in PowerDesigner.

CHAPTER 1 Getting Started with Object-Oriented Modeling

An *object-oriented model (OOM)* helps you analyze an information system through use cases, structural and behavioral analyses, and in terms of deployment, using the Unified Modeling Language (UML). You can model, reverse-engineer, and generate for Java, .NET and other languages.

The Unified Modeling Language (UML) is the standard language for object-oriented modeling. It was originally devised by Grady Booch, James Rumbaugh, and Ivar Jacobson, and is now controlled by the *OMG* (Object Management Group).

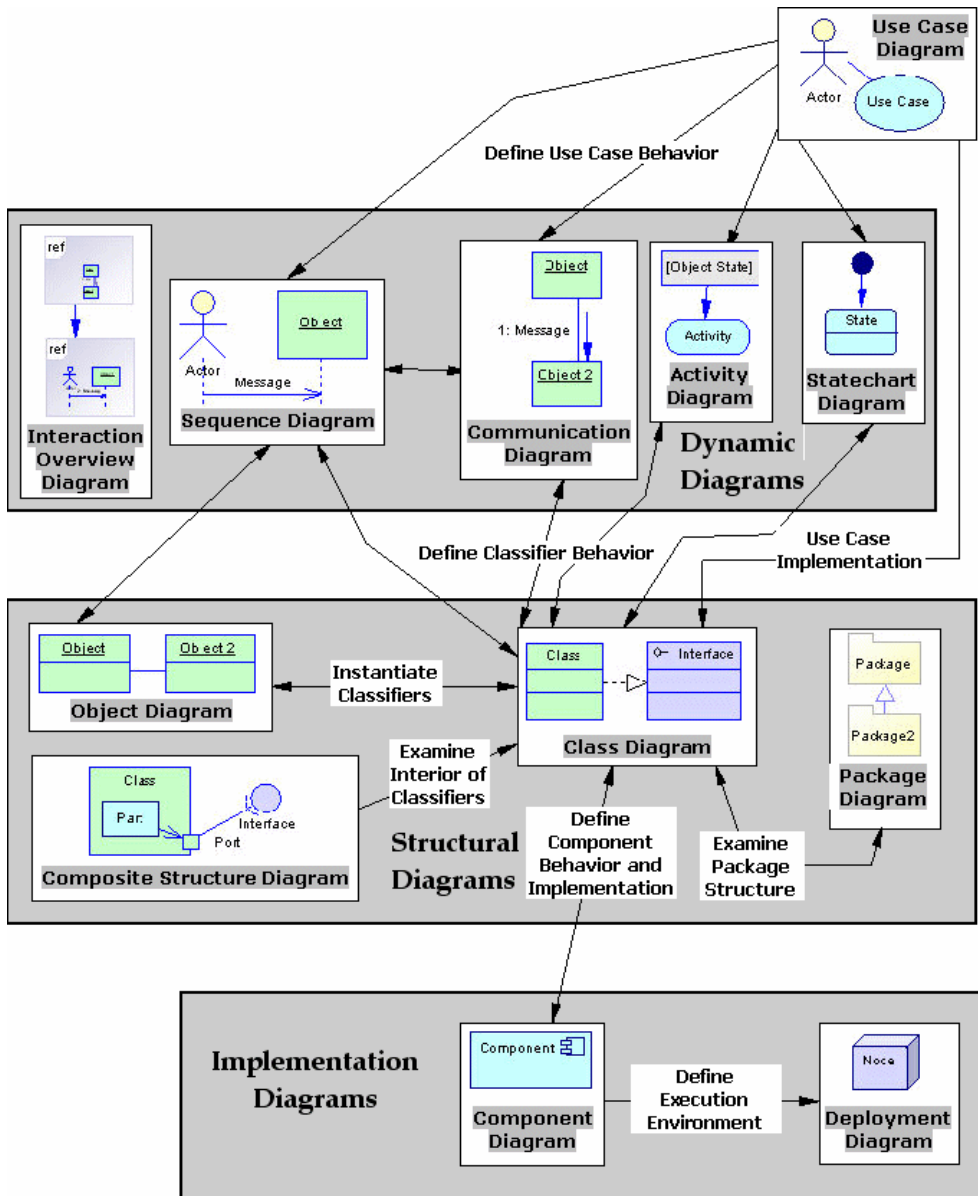

PowerDesigner® supports the following UML diagrams:

- Use case diagram 
- Structural Diagrams:
 - Class diagram 
 - Composite structure diagram 
 - Object diagram 
 - Package diagram 
- Dynamic Diagrams:
 - Communication diagram 
 - Sequence diagram 
 - Statechart diagram 
 - Activity diagram 
 - Interaction overview diagram 
- Implementation Diagrams:
 - Component diagram 
 - Deployment diagram 

For detailed information on these diagrams, see:

- *Chapter 3, Building Structural Diagrams* on page 21
- *Chapter 2, Building Use Case Diagrams* on page 9
- *Chapter 4, Building Dynamic Diagrams* on page 125
- *Chapter 5, Building Implementation Diagrams* on page 209

In the picture below, you can see how the various UML diagrams can interact within your model:

PowerDesigner

The PowerDesigner Object-Oriented Model is a powerful design tool for graphical object-oriented design implementation.

With this product, you can:

- Build an Object-Oriented Model (OOM) using the standard UML diagrams
- Generate and reverse engineer Java, C#, VB.NET, and PowerBuilder files
- Generate code for C++, Visual Basic, IDL-CORBA, etc.
- Generate EJB, servlets, and JSP components
- Generate Conceptual Data Models (CDMs), Physical Data Models (PDMs), XML Models (XSMs), and other Object-Oriented Models (OOMs) from your OOM
- Generate an OOM from a CDM, PDM, XML, or other OOM
- Import a Rose model
- Import/export XMI
- Customize the OOM to suit physical and performance considerations
- Customize and print model reports

Creating an OOM

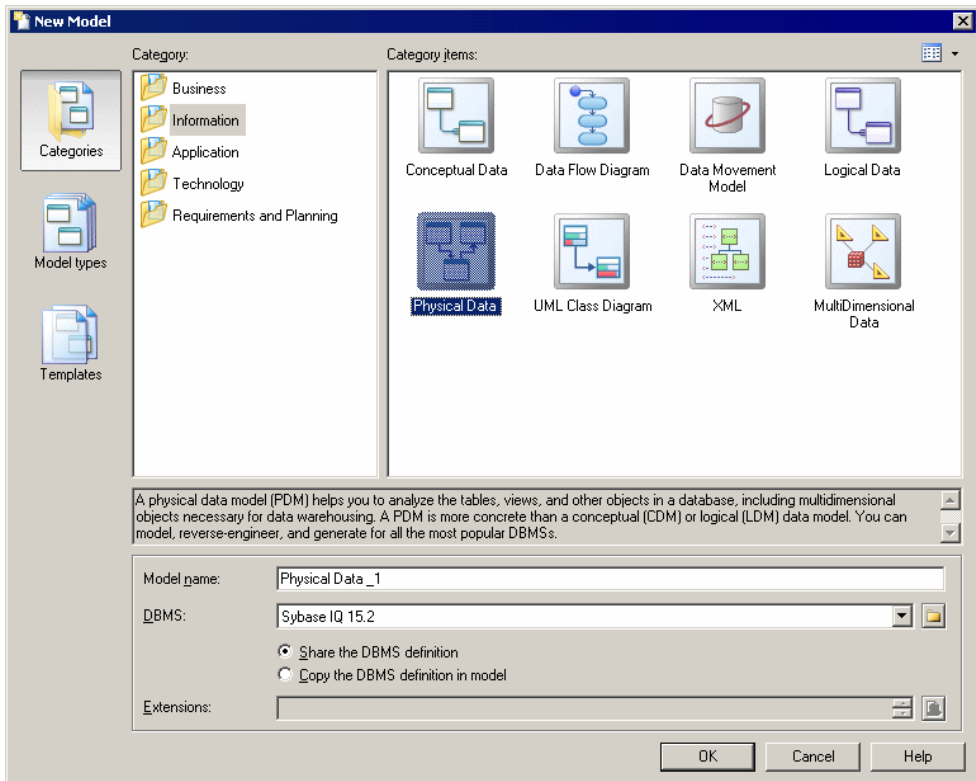

You create a new object-oriented model by selecting **File > New Model**.

Note: In addition to creating an OOM from scratch with the following procedure, you can also reverse-engineer a model from existing OO code (see *Reverse Engineering OO Source Files into an OOM* on page 279).

The New Model dialog is highly configurable, and your administrator may have hidden options that are not relevant for your work or provided templates or predefined models to

guide you through model creation. When you open the dialog, one or more of the following buttons will be available on the left hand side:

- **Categories** - which provides a set of predefined models and diagrams sorted in a configurable category structure.
- **Model types** - which provides the classic list of PowerDesigner model types and diagrams.
- **Template files** - which provides a set of model templates sorted by model type.

1. Select **File > New Model** to open the New Model dialog.
2. Click a button, and then select a category or model type (**Object-Oriented Model**) in the left-hand pane.
3. Select an item in the right-hand pane. Depending on how your New Model dialog is configured, these items may be first diagrams or templates on which to base the creation of your model.

Use the **Views** tool on the upper right hand side of the dialog to control the display of the items.

4. Enter a model name.

The code of the model, which is used for script or code generation, is derived from this name according to the model naming conventions.

5. [when available] Select an object language , and specify whether to:
 - **Share the object language definition** – creates a link to the file in the `Resource Files\ Object Languages` directory. Changes made to the target affect all models that share it.
 - **Copy the object language definition in model** – makes a copy of the resource file and saves it with the model. Changes made to the target affect only the current model.

For more information about PowerDesigner resource files, and how to add extensions to them, see the *Customizing and Extending PowerDesigner* manual.

6. [optional] Click the **Select Extensions** button and attach one or more extensions to your model.
7. Click **OK** to create and open the object-oriented model .

Note: Sample OOMs are available in the Example Directory.

OOM Properties

The Model property sheet displays the definition of the current model.

An OOM has the following model properties:

Property	Description
Name	Name for the model
Code	Code for the model. This code is used in scripts
Comment	Descriptive label for the model
Filename	Location of the model file. This box is empty if the model has never been saved
Author	Author of the model. You can insert a name, a space, or nothing. If you insert a space, the Author field in the title box remains empty. If you intentionally leave the box empty, the Author field in the title box displays the user name from the Version Info tab of the model property sheet
Version	Version of the model. You can use this box to display the repository version or a user defined version of the model. This parameter is defined in the display preferences of the Title node
Object language	Current object language for the model
Default diagram	Diagram displayed by default when opening the model

CHAPTER 2 Building Use Case Diagrams

A *use case diagram* is a UML diagram that provides a graphical view of the requirements of your system, and helps you identify how users interact with it.

With a use case diagram, you immediately see a snapshot of the system functionality. Further details can later be added to the diagram if you need to elucidate interesting points in the system behavior.

A use case diagram is well suited to the task of describing all of the things that can be done with a database system by all the people who might use it. However, it would be poorly suited to describing the TCP/IP network protocol because there are many exception cases, branching behaviors, and conditional functionality (what happens when the connection dies, what happens when a packet is lost?)

In the following example, the actor "photographer" does two things with the camera: take pictures and change the film. When he takes a picture, he has to switch the flash on, open the shutter, and then close the shutter but these activities are not of a high enough level to be represented in a use case.

Use Case Diagram Objects

PowerDesigner supports all the objects necessary to build use case diagrams.

Object	Tool	Symbol	Description
Actor			Used to represent an external person, process or something interacting with a system, sub-system or class. See <i>Actors (OOM)</i> on page 13.

Object	Tool	Symbol	Description
Use case			Defines a piece of coherent behavior in a system, without revealing its internal structure. See <i>Use Cases (OOM)</i> on page 10.
Association			Communication path between an actor and a use case that it participates in. See <i>Use Case Associations (OOM)</i> on page 18.
Generalization			A link between a general use case and a more specific use case that inherits from it and add features to it. See <i>Generalizations (OOM)</i> on page 97.
Dependency			Relationship between two modeling elements, in which a change to one element will affect the other element. See <i>Dependencies (OOM)</i> on page 100.

Creating a Use Case Diagram

You can create a use case diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Use Case Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Use Case Diagram**.

To create a new OOM with a use case diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Use Case Diagram** as the first diagram, and click **OK**.

Use Cases (OOM)

A *use case* is an interaction between a user and a system (or part of a system). It defines a discrete goal that a user wants to achieve with the system, without revealing the system's internal structure.

A use case can be created in the following diagrams:

- Use Case Diagram

Example

In this example, "buy tickets" and "buy subscriptions" are use cases.

Creating a Use Case

You can create a use case in any of the following ways:

- Use the Use Case tool in the diagram Palette
- Select **Model > Use Cases** to access the List of Use Cases, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Use Case**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Use Case Properties

You can modify an object's properties from its property sheet. To open a use case property sheet, double-click its diagram symbol or its Browser entry in the Use Cases folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs.

Use Case Property Sheet Specification Tab

The Specification tab contains the following properties, available via sub-tabs at the bottom of the dialog box:

Property	Description
Action Steps	Provides a textual description of the normal sequence of actions associated with a use case. For example, the action steps for a use case called 'register patient' in a hospital might be as follows: "Open a file, give a new registration number, write down medical treatment".
Extension Points	Provides a textual description of actions that extend the normal sequence of actions. Extensions are usually introduced with an "ifthen" statement. For example, an extension to the action steps above might be: "If the patient already has a registration number, then retrieve his personal file".
Exceptions	Specifies signals raised in response to errors during system execution.
Pre-Conditions	Specifies constraints that must be true for an operation to be invoked.
Post-Conditions	Specifies constraints that must be true for an operation to exit correctly.

Each of these sub-tabs contains a text box (RTF or TXT format) which lets you give a more detailed definition of a use case.

Use Case Property Sheet Implementation Classes Tab

The Implementation Classes tab in the use case property sheet shows the list of classes, or interfaces used to implement a use case. A use case is generally a task or service, represented as a verb. When analyzing what a use case must do, you can identify the classes and interfaces that need to be created to fulfill the task, and attach them to a use case.

Creating a Class or an Interface

To add a class or interface to the list, use one of the following tools:

Tool	Action
	Add Objects – Opens a dialog box from which you can select any class or interface currently existing in the model to implement the use case.
	Create a New Class – Creates a new class to implement the use case. The new class is available in the Classes folder of the current model or package in the Browser for use in other diagrams.

whose behavior you cannot control or change, because they are not part of the system that you are describing.

An actor can be created in the following diagrams:

- Communication Diagram
- Sequence Diagram
- Use Case Diagram

A single actor object may be used in a use case, a sequence, and a communication diagram if it plays the same role in each. Each actor object is available to all the diagrams in your OOM. They can either be created in the diagram type you need, or dragged from a diagram type and dropped into another diagram type.

Actors in a Use Case Diagram

In the use case diagram, an actor is a *primary actor* for a use case if he asks for and/or triggers the actions performed by a use case. Primary actors are located to the left of the use case, and the association linking them should be drawn from the actor to the use case.

An actor is a *secondary actor* for a use case if it does not trigger the actions, but rather assists the use case to complete the actions. After performing an action, the use case may give results, documents, or information to the outside and, if so, the secondary actor may receive them. Secondary actors are located to the right of the use case, and the association linking them should be drawn from the use case to the actor.

On a global scale, a secondary actor for one use case may be a primary actor for another use case, either in the same or another diagram.

Actors in a Communication Diagram

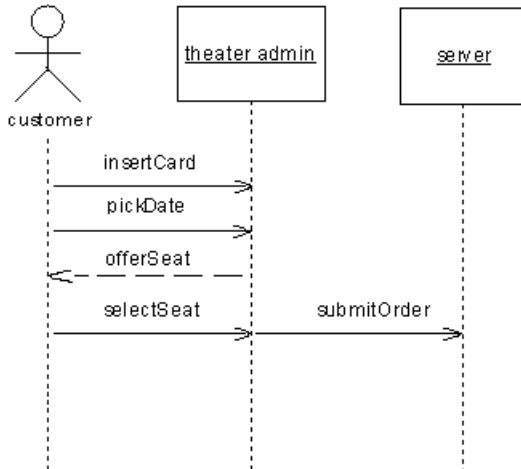

In a communication diagram, an actor may be connected to an object by an instance link, or may send or receive messages.

Actors in a Sequence Diagram

In the sequence diagram, an actor has a lifeline representing the duration of its life. You cannot separate an actor and its lifeline.

If an actor is the invoker of the interaction, it is usually represented by the first (farthest left) lifeline in the sequence diagram. If you have several actors in the diagram, you should try to position them to the farthest left or to the farthest right lifelines because actors are, by definition, external to the system.

Creating an Actor

To create an actor:

- Use the Actor tool in the diagram Palette
- Select **Model** > **Actors** to access the List of Actors, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New** > **Actor**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Actor Properties

You can modify an object's properties from its property sheet. To open an actor property sheet, double-click its diagram symbol or its Browser entry in the Actors folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs.

Actor Property Sheet Implementation Classes Tab

The Implementation Classes tab shows the list of classes and interfaces used to implement an actor. An actor can be a human being (person, partner) or a machine, or process (automated system). When analyzing what an actor must do, you can identify the classes and interfaces that need to be created for the actor to perform his task, and attach them to the actor.

Creating a Class or an Interface

To add a class or interface to the list, use one of the following tools:

Tool	Action
	Add Objects – Opens a dialog box from which you can select any class or interface currently existing in the model to implement the actor.
	Create a New Class – Creates a new class to implement the actor. The new class is available in the Classes folder of the current model or package in the Browser for use in other diagrams.
	Create a New Interface - Creates a new interface to implement the actor. The new interface is available in the Interfaces folder of the current model or package in the Browser for use in other diagrams.

For example, an actor Car needs the classes Engine and Motorway to perform its task. They are shown as related to the actor in the following figure:

Actor Property Sheet Related Diagrams Tab

The Related Diagrams tab lists other diagrams in the present model that relate to the actor. Click the Add Objects tool to add diagrams to the list.

For more information see "Defining related diagrams" in the Diagrams and Symbols chapter of the *Core Features Guide*.

Reusing Actors

The same actor can be used in a Use Case Diagram, Communication Diagram, and Sequence Diagram. To reuse an actor created in one diagram in another diagram:

- Select the actor you need in the Browser, and drag it and drop it into the new diagram.
- Select **Symbols > Show Symbols** in the new diagram to open the Show Symbols dialog box, select the actor to display, and click OK.

Use Case Associations (OOM)

An *association* is a unidirectional relationship that describes a link between objects.

A use case association can be created in the following diagrams:

- Use Case Diagram

You can create an association between:

- An actor and a use case
- A use case and an actor

Associations in a use case diagram are very similar to those in class diagrams. However, it is not possible to specify roles, cardinalities and navigability for associations.

The orientation of the association is defined by the way it is created graphically. An association leading from an actor to a use case is an *input* association. An association leading from a use case to an actor is an *output* association.

If the orientation of the association is not displayed, you can modify the association display preferences.

Example

Creating a Use Case Association

You can create a use case association in any of the following ways:

- Use the Use Case Association tool in the diagram Palette
- Select **Model > Associations** to access the List of Associations, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Association**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Use Case Association Properties

You can modify an object's properties from its property sheet. To open an association property sheet, double-click its diagram symbol or its Browser entry in the Associations folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.

Property	Description
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs.
Orientation	Defines the direction of the association. You can choose between: <ul style="list-style-type: none"> • Primary Actor – the association leads from the actor to the use case • Secondary Actor – the association leads from the use case to the actor
Source	Specifies the object that the association leads from. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Destination	Specifies the object that the association leads to You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.

CHAPTER 3 Building Structural Diagrams

The diagrams in this chapter allow you to model the static structure of your system. PowerDesigner provides three types of diagrams for modeling your system in this way, each of which offers a different view of your objects and their relationships:

- A *class diagram* shows the static structure of the classes that make up the system. You use a class diagram to identify the kinds of objects that will compose your system, and to define the ways in which they will be associated. For more information, see *Class Diagram Basics* on page 21.
- A *composite structure diagram* allows you to define in greater detail the internal structure of your classes and the ways that they are associated with one another. You use a composite structure diagram in particular to model complex forms of composition that would be very cumbersome to model in a class diagram. For more information, see *Composite Structure Diagram Basics* on page 24.
- An *object diagram* is like a class diagram, except that it shows specific object instances of the classes. You use an object diagram to represent a snapshot of the relationships between actual instances of classes. For more information, see *Object Diagram Basics* on page 26.
- A *package diagram* shows the structure of the packages that make up your application, and the relationships between them. For more information, see *Package Diagram Basics* on page 28.

Class Diagram Basics

A *class diagram* is a UML diagram that provides a graphical view of the classes, interfaces, and packages that compose a system, and the relationships between them.

You build a class diagram to simplify the interaction of objects in the system you are modeling. Class diagrams express the static structure of a system in terms of classes and relationships between those classes. A class describes a set of objects, and an association describes a set of links; objects are class instances, and links are association instances.

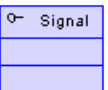

A class diagram does not express anything specific about the links of a given object, but it describes, in an abstract way, the potential link from an object to other objects.

The following example shows the process of product order and shipment in a class diagram.

Class Diagram Objects

PowerDesigner supports all the objects necessary to build class diagrams.

Object	Tool	Symbol	Description
Class			Set of objects sharing the same attributes, operations, methods, and relationships. See <i>Classes (OOM)</i> on page 29.
Interface			Descriptor for the externally visible operations of a class, object, or other entity without specification of internal structure. See <i>Interfaces (OOM)</i> on page 52.
Port			Interaction point between a classifier and its environment. See <i>Ports (OOM)</i> on page 62.
Generalization			Link between classes showing that the sub-class shares the structure or behavior defined in one or more superclasses. See <i>Generalizations (OOM)</i> on page 97.
Require Link			Connects a class, component, or port to an interface. See <i>Require Links (OOM)</i> on page 105.
Association			Structural relationship between objects of different classes. See <i>Associations (OOM)</i> on page 86.

Object	Tool	Symbol	Description
Aggregation			A form of association that specifies a part-whole relationship between a class and an aggregate class (example: a car has an engine and wheels). See <i>Associations (OOM)</i> on page 86.
Composition			A form of aggregation but with strong ownership and coincident lifetime of parts by the whole; the parts live and die with the whole (example: an invoice and its invoice line). See <i>Associations (OOM)</i> on page 86.
Dependency			Relationship between two modeling elements, in which a change to one element will affect the other element. See <i>Dependencies (OOM)</i> on page 100.
Realization			Semantic relationship between classifiers, in which one classifier specifies a contract that another classifier guarantees to carry out. See <i>Realizations (OOM)</i> on page 103.
Inner link			Exists when a class is declared within another class or interface. See <i>Composite and inner classifiers</i> on page 43.
Attribute	N/A	N/A	Named property of a class. See <i>Associations (OOM)</i> on page 86.
Operation	N/A	N/A	Service that can be requested from a class. See <i>Operations (OOM)</i> on page 76.

Creating a Class Diagram

You can create a class diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Class Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Class Diagram**.

To create a new OOM with a class diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Class Diagram** as the first diagram, and click **OK**.

Composite Structure Diagram Basics

A *composite structure diagram* is a UML diagram that provides a graphical view of the classes, interfaces, and packages that compose a system, including the ports and parts that describe their internal structures.

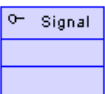

A composite structure diagram performs a similar role to a class diagram, but allows you to go into further detail in describing the internal structure of multiple classes and showing the interactions between them. You can graphically represent inner classes and parts and show associations both between and within classes.

In the following example, the internal structures of the classes TitleSql (which contains two inner classes) and TitleImp (which contains two parts) are connected via the interfaces dmlAccess and java.sql.connection1:

Composite Structure Diagram Objects

PowerDesigner supports all the objects necessary to build composite structure diagrams.

Object	Tool	Symbol	Description
Class			Set of objects sharing the same attributes, operations, methods, and relationships. See <i>Classes (OOM)</i> on page 29.
Interface			Descriptor for the externally visible operations of a class, object, or other entity without specification of internal structure. See <i>Interfaces (OOM)</i> on page 52.
Port			Interaction point between a classifier and its environment. See <i>Ports (OOM)</i> on page 62.
Part			Classifier instance playing a particular role within the context of another classifier. See <i>Parts (OOM)</i> on page 60.

Object	Tool	Symbol	Description
Generalization			Link between classes showing that the sub-class shares the structure or behavior defined in one or more superclasses. See <i>Generalizations (OOM)</i> on page 97.
Require Link			Connects classifiers to interfaces. See <i>Require Links (OOM)</i> on page 105.
Assembly Connector			Connects parts to each other. See <i>Assembly Connectors (OOM)</i> on page 106.
Delegation Connector			Connects parts to ports on the outside of classifiers. See <i>Delegation Connectors (OOM)</i> on page 108.
Association			Structural relationship between objects of different classes. See <i>Associations (OOM)</i> on page 86.
Aggregation			A form of association that specifies a part-whole relationship between a class and an aggregate class (example: a car has an engine and wheels). See <i>Associations (OOM)</i> on page 86.
Composition			A form of aggregation but with strong ownership and coincident lifetime of parts by the whole; the parts live and die with the whole (example: an invoice and its invoice line). See <i>Associations (OOM)</i> on page 86.
Dependency			Relationship between two modeling elements, in which a change to one element will affect the other element. See <i>Dependencies (OOM)</i> on page 100.
Realization			Semantic relationship between classifiers, in which one classifier specifies a contract that another classifier guarantees to carry out. See <i>Realizations (OOM)</i> on page 103.
Attribute	N/A	N/A	Named property of a class. See <i>Associations (OOM)</i> on page 86.
Operation	N/A	N/A	Service that can be requested from a class. See <i>Operations (OOM)</i> on page 76.

Creating a Composite Structure Diagram

You can create a composite structure diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Composite Structure Diagram** from the contextual menu
- Right-click the background of any diagram and select **Diagram > New Diagram > Composite Structure Diagram** from the contextual menu

To create a new OOM with a composite structure diagram, select **File > New**, choose Object-Oriented Model from the Model type list, choose Composite structure Diagram as the first diagram, and click OK.

Object Diagram Basics

An *object diagram* is a UML diagram that provides a graphical view of the structure of a system through concrete instances of classes (objects), associations (instance links), and dependencies.

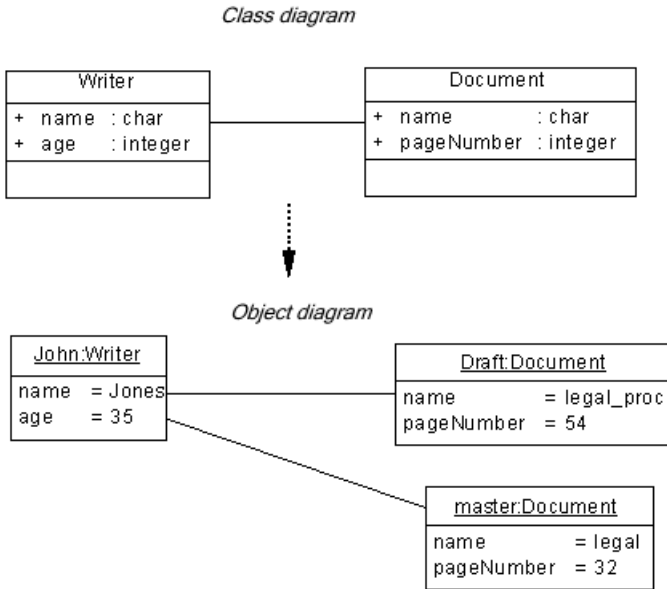

As a diagram of instances, the object diagram shows an example of data structures with data values that corresponds to a detailed situation of the system at a particular point in time.

The object diagram can be used for analysis purposes: constraints between classes that are not classically represented in a class diagram can typically be represented in an object diagram.

If you are a novice in object modeling, instances usually have more meaning than classifiers do, because classifiers represent a level of abstraction. Gathering several instances under the same classifier helps you to understand what classifiers are. Moreover, even for analysts used to abstraction, the object diagram can help understand some structural constraints that cannot be easily graphically specified in a class diagram.

In this respect, the object diagram is a limited use of a class diagram. In the following example, the class diagram specifies that a class `Writer` is linked to a class `Document`.

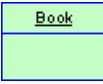

The object diagram, deduced from this class diagram, highlights some of the following details: the object named John, instance of the class `Writer` is linked to two different objects `Draft` and `Master` that are both instances of the class `Document`.

Note: You can drag classes and associations from the Browser and drop them into an object diagram. If you drag classes, new objects as instances of classes are created. If you drag an association, a new instance link as instance of the association, and two objects are created.

Object Diagram Objects

PowerDesigner supports all the objects necessary to build object diagrams.

Object	Tool	Symbol	Description
Object			Instance of a class. See <i>Objects (OOM)</i> on page 55.
Attribute values	N/A	N/A	An attribute value represents an instance of a class attribute, this attribute being in the class related to the object. See <i>Object property sheet Attribute Values tab</i> on page 57.
Instance link			Communication link between two objects. See <i>Instance Links (OOM)</i> on page 114.
Dependency			Relationship between two modeling elements, in which a change to one element will affect the other element. See <i>Dependencies (OOM)</i> on page 100.

Creating an Object Diagram

You can create an object diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Object Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Object Diagram**.

To create a new OOM with an object diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Object Diagram** as the first diagram, and click **OK**.

Package Diagram Basics

A *package diagram* is a UML diagram that provides a high-level graphical view of the organization of your application, and helps you identify generalization and dependency links between the packages.

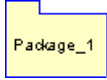

You can control the level of detail shown for each package, by toggling between the standard and composite package views via the Edit or contextual menus.

In the following example, the WebShop package imports the Cart package, which, in turn, imports the Types package, and has access to the Auxiliary package. The Types package is shown in composite (sub-diagram) view:

Package Diagram Objects

PowerDesigner supports all the objects necessary to build package diagrams.

Object	Tool	Symbol	Description
Package			A container for organizing your model objects. See <i>Packages (OOM)</i> on page 48.

Object	Tool	Symbol	Description
Generalization			Link between packages showing that the sub-package shares the structure or behavior defined in one or more super-packages. See <i>Generalizations (OOM)</i> on page 97.
Dependency			Relationship between two packages, in which a change to one package will affect the other. See <i>Dependencies (OOM)</i> on page 100.

Creating a Package Diagram

You can create a package diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Package Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Package Diagram**.

To create a new OOM with a package diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Package Diagram** as the first diagram, and click **OK**.

Classes (OOM)

A *class* is a description of a set of objects that have a similar structure and behavior, and share the same attributes, operations, relationships, and semantics.

A class can be created in the following diagrams:

- Class Diagram
- Composite Structure Diagram

The structure of a class is described by its *attributes* and *associations*, and its behavior is described by its *operations*.

Classes, and the relationships that you create between them, form the basic structure of an OOM. A class defines a concept within the application being modeled, such as:

- a physical thing (like a car),
- a business thing (like an order)
- a logical thing (like a broadcasting schedule),
- an application thing (like an OK button),
- a behavioral thing (like a task)

The following example shows the class Aircraft with its attributes (range and length) and operation (startengines).

aircraft
+ range : int
+ length : int
+ startengines() : void

Creating a Class

You can create a class in any of the following ways:

- Use the Class tool in the diagram Palette
- Select **Model > Classes** to access the List of Classes, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Class**
- Right-click an interface, and select Create Class from the contextual menu (this method allows you to inherit all the operations of the interface, including the getter and setter operations, creates a realization link between the class and the interface, and shows this link in the Realizes sub-tab of the Dependencies tab of the class property sheet).

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Class Properties

You can modify an object's properties from its property sheet. To open a class property sheet, double-click its diagram symbol or its Browser entry in the Classes folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for classes.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Extends	Specifies the parent class (to which the present class is linked by a generalization). Click the Select Classifier tool to the right to specify a parent class and click the Properties tool to access its property sheet.

Property	Description
Stereotype	<p>Extends the semantics of the object beyond the core UML definition. The following common stereotypes are available by default:</p> <ul style="list-style-type: none"> • <<actor>> - Coherent set of roles that users play • <<enumeration>> - List of named values used as the range of an attribute type • <<exception>> - Exception class, mainly used in relation to error messages • <<implementationClass>> - Class whose instances are statically typed. Defines the physical data structure and methods of a class as implemented in traditional programming languages • <<process>> - Heavyweight flow that executes concurrently with other processes • <<signal>> - Specification of asynchronous stimulus between instances • <<metaclass>> - a metaclass of some other class • <<powertype>> - a metaclass whose instances are sub-classes of another class • <<thread>> - Lightweight flow that executes concurrently with other threads within the same process. Usually executes inside the address space of an enclosing process • <<type>> - Abstract class used to specify the structure and behavior of a set of objects but not the implementation • <<utility>> - Class that has no instances <p>Other language-specific stereotypes may be available. These stereotypes are defined in the object language file. For more information, see "Stereotypes (Profile)" in the Extending your Models with Profiles chapter of the <i>Customizing and Extending PowerDesigner</i> manual.</p>
Visibility	<p>Specifies the visibility of the object, how it is seen outside its enclosing namespace. When a class is visible to another object, it may influence the structure or behavior of the object, and/or be affected by it. You can choose between:</p> <ul style="list-style-type: none"> • Private – only to the object itself • Protected – only to the object and its inherited objects • Package – to all objects contained within the same package • Public – to all objects (option by default)
Cardinality	<p>Specifies the number of instances a class can have. You can choose between:</p> <ul style="list-style-type: none"> • 0..1 – None to one • 0..* – None to an unlimited number • 1..1 – One to one • 1..* – One to an unlimited number • * – Unlimited number

Property	Description
Type	<p>Allows you to specify that a class is a generic type, or that it is bound to one. You can choose between:</p> <ul style="list-style-type: none"> • Class • Generic • Bound – If you select this option, then an additional list becomes available to the right, where you can specify the generic type to which the class is bound. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object. <p>If you specify either Generic or Bound, then the Generic tab is displayed, allowing you to control the associated type variables (see <i>Class property sheet Generic tab</i> on page 33). For more information on generic types and binding classes to them, see <i>Generic types and methods</i> on page 40.</p>
Abstract	Specifies that the class cannot be instantiated and therefore has no direct instances.
Final	Specifies that the class cannot have any inherited objects.
Generate code	Specifies that the class is included when you generate code from the model, it does not affect inter-model generation.

The following tabs list objects associated with the class:

- Attributes - lists the attributes associated with the class. Click the Inherited button to review the public and protected attributes inherited from a parent class. You can create attributes, including accessors, directly in this tab, or add already existing attributes. For more information, see *Attributes (OOM)* on page 65.
- Identifiers - lists the identifiers associated with the class. You can create identifiers directly in this tab. For more information, see *Identifiers (OOM)* on page 73.
- Operations - lists the operations associated with the class. You can create operations directly in this tab, or add already existing operations. For more information, see *Operations (OOM)* on page 76.
- Ports - lists the ports associated with the class. You can create ports directly in this tab. For more information, see *Ports (OOM)* on page 62.
- Parts - lists the parts associated with the class. You can create parts directly in this tab. For more information, see *Parts (OOM)* on page 60.
- Associations - lists the associations associated with the class. For more information, see *Associations (OOM)* on page 86.
- Inner Classifiers - lists the inner classes and interfaces associated with the class. You can create inner classifiers directly in this tab. For more information, see *Composite and inner classifiers* on page 43.

- Related Diagrams - lists the model diagrams that are related to the class. You can add diagrams in this tab. For more information see "Defining related diagrams" in the Diagrams and Symbols chapter of the *Core Features Guide*.

Class Property Sheet Detail Tab

The Detail tab contains a Persistent groupbox whose purpose is to defined the persistent generated code of a class during OOM to CDM or PDM generation.

The complete list of options on this tab is as follows:

Property	Description
Persistent	<p>Specifies that the class must be persisted in a generated CDM or PDM. You have to select one of the following options:</p> <ul style="list-style-type: none"> • Generate table - the class is generated as an entity or table. • Migrate columns – [PDM only] the class is not generated, and its attributes and associations are migrated to the generated parent or child table. • Generate ADT – [PDM only] the class is generated as an abstract data type. See "Abstract Data Types", in the Building Physical Diagrams chapter of the <i>Data Modeling</i> guide. • Value Type – the class is not generated, and its attributes are generated in their referencing types. <p>For more information on object persistence, see <i>Managing Object Persistence During OOM to PDM Generation</i> on page 292.</p>
Code	<p>Specifies the code of the table or entity that will be generated from the current class in a CDM or PDM model. Persistent codes are used for round-trip engineering: the same class always generates the same entity or table with a code compliant with the target DBMS.</p> <p>Example: to generate a class Purchaser into a table PURCH, type <i>PURCH</i> in the Code box.</p>
Inner to	<p>Specifies the name of the class or interface to which the current class belongs as an inner classifier</p>
Association class	<p>Specifies the name of the association related to the class to form an association class. The attributes and operations of the current class are used to complement the definition of the association.</p>

For more information on other properties specific to Web services, see *Detail Tab of the Class* on page 243.

Class Property Sheet Generic Tab

The Generic tab allows you to specify either:

- That the class is a generic type, and to list its type parameters, or
- That the class is bound to a generic type, and to give values for the required type parameters

For more information, see *Generic types and methods* on page 40.

Class Property Sheet Script Tab

The Script tab allows you to customize the object's creation script by, for example, adding descriptive information about the script.

Examples

If a development project archives all the creation scripts that are generated, a header script can be inserted before each creation script, indicating the date, time, and any other information specific to the generated script.

If an organization requires that generated scripts are filed using a naming system which may be independent from a script name, a header script could direct a generated script to be filed under a different name than the name indicated in the creation script.

Scripts can be customized as follows:

- Insert scripts at the beginning (Header page) and the end (Footer page) of a script
- Insert scripts before and after a class or interface creation command (Imports page)

Script Tools

The following tools and shortcut keys are available on the Script tab:

Tool	Description	Shortcut Key
	Open Editor Contextual menu	Shift + F11
	Edit With - Opens the default editor you previously defined or allows you to select another editor if you click the down arrow beside this tool	ctrl + E
	Import Folder - Available in the Imports tabbed page only. Opens a selection window to select packages to import. The packages are added where the cursor is positioned. They are prefixed by the keyword 'import'	—
	Import Classifier - Available in the Imports tabbed page only. Opens a selection window to select classifiers to import. The classifiers are added where the cursor is positioned. They are prefixed by the keyword 'import'	—

For more information on defining a default editor, see section "Specifying text editors" in the Models chapter of the *Core Features Guide*.

Formatting Variables in Customized Scripts

Variables have a syntax that can force a format on their values in the following ways:

- Force values to lowercase or uppercase characters
- Truncate the length of values

When a variable does not specify formatting, its values have the same format as in the OOM. You can use the following formatting syntax with variables:

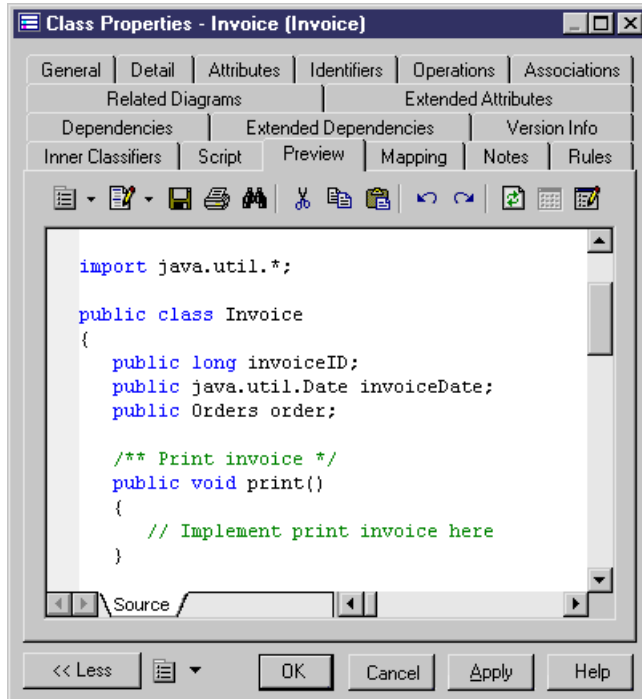

Format code	Format of variable value in script
.L	Lowercase characters
.T	Removes blank spaces
.U	Uppercase characters
.c	Upper-case first letter and lower-case next letters
.n	Maximum length where n is the number of characters
.nJ	Justifies to fixed length where n is the number of characters

You embed formatting options in variable syntax as follows:

```
%.format:variable%
```

Class Property Sheet Preview Tab

The Preview tab allows you to preview the code that will be generated for the class.

Preview Tools

The following tools and shortcut keys are available on the Preview tab:

Tool	Description	Shortcut Key
	Open Editor Contextual menu.	Shift + F11
	Refresh.	F5
	Show Generation Options - This dialog box allows you to change generation options and see the impact on the code. This feature is especially useful when you are working with Java. For other object languages, generation options do not influence the code.	ctrl + W
	Select Generation Targets - displays the list of targets for the current object. If you add a generation target, the corresponding tab is added to the Preview tab. If you deselect a generation target, the corresponding tab disappears from the Preview tab. This option is only available when at least one extended model definition flagged for generation is linked to the model, and when it contains Generated Files entries for the current object. For more information on generation targets, see "Extended Model Definitions" in the Resource Files and the Public Metamodel chapter of the <i>Customizing and Extending PowerDesigner</i> manual.	ctrl + F6

Script Bookmarks

In the Preview tab, you can add and remove bookmarks at specific points in the code and then navigate forwards or backwards from bookmark to bookmark:

Shortcut	Description
ctrl + F2	Adds a new bookmark. A blue bookmark box is displayed. If you repeat this action from the same position, the bookmark is deleted and the blue marker disappears
F2	Jumps to bookmark
shift + F2	Jumps to previous bookmark

Note that bookmarks are not printable and are lost if you use the Refresh, or Show Generation Options tools.

Creating Java BeanInfo Classes

If you are using the Java object language, you can create Java BeanInfo classes from any class with a type of "JavaBean".

A JavaBean is a reusable software component written in Java that can be manipulated visually in a builder tool. A Java BeanInfo class is used as a standard view of a Bean. Each JavaBean can implement a BeanInfo class. Bean implementors may want to provide explicit information about the methods, properties, and events of a Bean by providing a Java BeanInfo class.

The BeanInfo class is generated with an attribute, and the following operations:

- constructor
- getPropertyDescriptors();
- getMethodDescriptors();

You can view the complete code by clicking the Preview tab in the BeanInfo class property sheet.

Attribute Created

The attribute has the following code:

```
private static final Class <ClassCode>Class = <ClassCode>.class;
```

Operations Created

The constructor has the following code:

```
<ClassCode>BeanInfo()
{
    super();
}
```

The getPropertyDescriptors() operation has the following code:

```
public PropertyDescriptor[] getPropertyDescriptors ()
{
    // Declare the property array
    PropertyDescriptor properties[] = null;

    // Set properties
    try
    {
        // Create the array
        properties = new PropertyDescriptor[<nbProperties>];
        // Set property 1
        properties[0] = new
PropertyDescriptor("<propertyCode1>" ,<ClassCode>Class;
        properties[0].setConstrained(false);
        properties[0].setDisplayName("propertyName1");
        properties[0].setShortDescription("propertyComment1");
        // Set property 2
```

```

    properties[1] = new
PropertyDescriptor("<propertyCode2>" ,<ClassCode>Class;
    properties[1].setConstrained(false);
    properties[1].setDisplayName("propertyName2");
    properties[1].setShortDescription("propertyComment2");

}
catch
{
    // Handle errors
}
return properties;
}

```

The `getMethodDescriptors()` operation has the following code:

```

public MethodDescriptor[] getMethodDescriptors ()
{
    // Declare the method array
    MethodDescriptor methods[] = null;
    ParameterDescriptor parameters[] = null;

    // Set methods
    try
    {
        // Create the array
        methods = new MethodDescriptor[<nbMethods>];
        // Set method 1
        parameters = new ParameterDescriptor[<nbParameters1>];
        ParameterDescriptor();
        parameters[0].setName("parameterCode1");
        parameters[0].setDisplayName("parameterName1");
        parameters[0].setShortDescription("parameterComment1");
        methods[0] = new MethodDescriptor("<methodCode1>", parameters);
        methods[0].setDisplayName("methodName1");
        methods[0].setShortDescription("methodComment1");
        // Set method 2
        methods[1] = new MethodDescriptor("<methodCode2>");
        methods[1].setDisplayName("methodName2");
        methods[1].setShortDescription("methodComment2");

    }
    catch
    {
        // Handle errors
    }
    return methods;
}

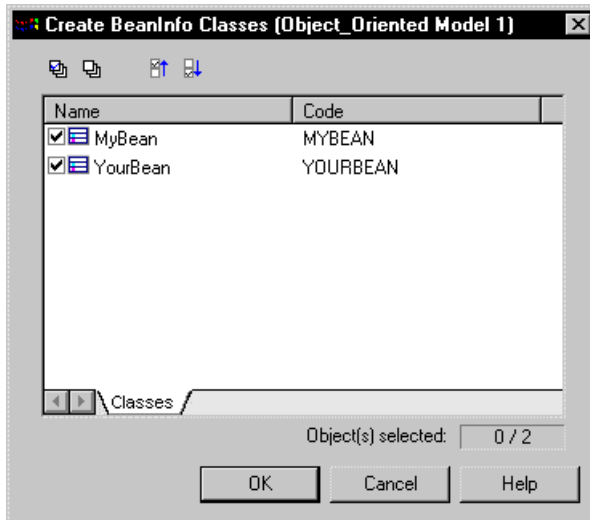

```

When you create a Java BeanInfo class, a dependency link is automatically created between both classes and the stereotype of the Java BeanInfo class is set to <<BeanInfo>>.

Creating a Java BeanInfo Class from the Language Menu

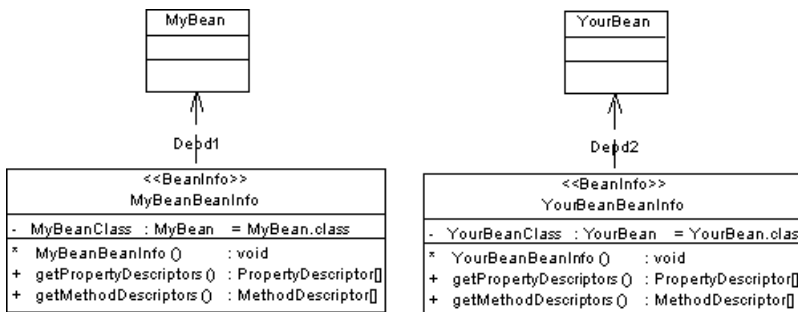

You can create a Java BeanInfo class from the Language menu.

1. Select **Language > Create BeanInfo Classes** to display the Create BeanInfo Classes selection window. This window contains a list of all the classes of type JavaBean in the model.

2. Select the classes for which you want to generate Java BeanInfo classes and click OK.

A BeanInfo class is created in the model for each selected class.

Creating a Java BeanInfo Class from the Class Contextual Menu

can create a Java BeanInfo class from the class contextual menu.

Right-click a class in the diagram, and select Create BeanInfo Class from the contextual menu.

Generic Types and Methods

Generic types and methods are a new feature of Java 5.0. A generic type is a class or interface that has one or more type variables and one or more methods that use a type variable as a placeholder for an argument or return type.

Using generic types and methods allows you to take advantage of stronger compile-time type checking. When a generic type is used, an actual type is specified for each type variable. This additional type information is used by the compiler to automatically cast the associated return values.

Creating Generic Types

PowerDesigner allows you to designate classes and interfaces as generic types.

You define a list of type variables that will be used as datatypes for attributes, method parameters, or return types. PowerDesigner requires the existence of a bound class to create a generalization, realization, or association.

You then bind a classifier to the generic type via this intermediate bound class, and specify the actual types to be used in place of the required type variables.

1. Open the property sheet of the class or interface, and select Generic from the Type list on the General tab. The Generic tab will be automatically displayed, and a type variable created in the list in the tab.
2. Click the Generic tab, and add any additional type variables that you require with the Add a Row tool. You can also specify a derivation constraint in the form of a list of types.
3. Click OK to return to the diagram. The classifier symbol will now display the type variables on its top-left corner.

In order for the classifier to become a true generic type, it must contain at least one generic method.

Creating Generic Methods

PowerDesigner allows you to designate operations as generic methods. Generic methods are methods that have their own list of type variables.

1. Open the property sheet of the class or interface and click on its Operations tab.
2. Click the Add a Row tool to create a new operation, and then click the Properties tool to open its property sheet.
3. Click Yes to confirm the creation of the operation, and then select the Generic checkbox on the General tab of the new operation property sheet to designate the operation as a generic

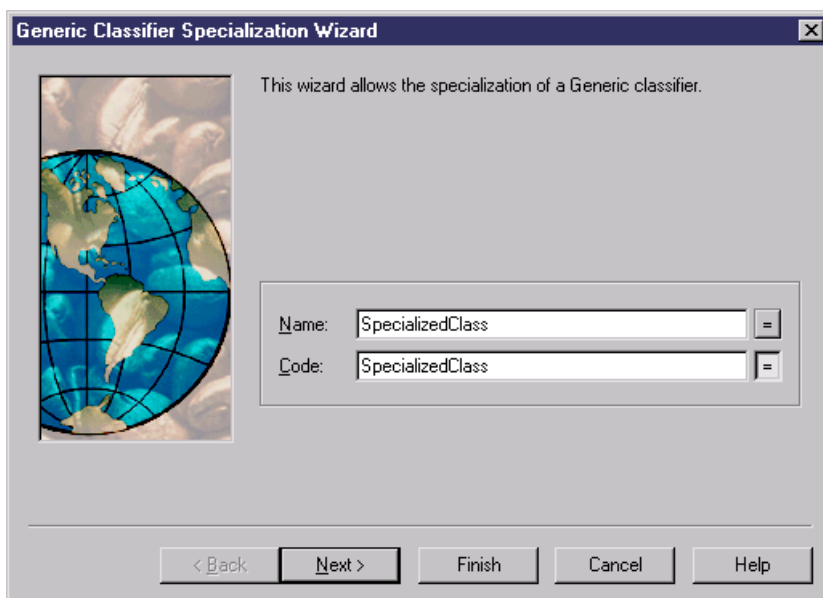

method. The Generic tab will be automatically displayed, and a type variable created in the list in the tab.

4. Add any additional type variables that you require with the Add a Row tool, and then click OK.

Creating a Specialized Classifier

If you need to create a classifier that will inherit from a generic type, you must create an intermediary bound classifier. The Generic Classifier Specialization Wizard can perform these steps for you.

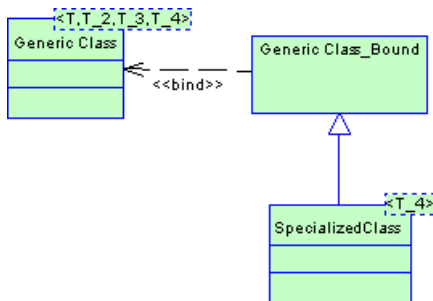

1. Right-click a generic class or interface, and select Create Specialized Class (or Interface) from the contextual menu to open the Generic Classifier Specialization Wizard:

2. Enter a Name and Code for the specialized classifier, and then click Next to go to the type parameters page.
3. Specify values for each of the type parameters in the list. If you do not specify a value for a type parameter, it will be added as a type parameter to the new specialized classifier.
4. Click Finish to return to the diagram. The wizard will have created the specialized classifier and also a bound classifier which acts as an intermediary between the generic and the specialized classifiers, in order to specify values for the type parameters.

The bound classifier is attached to the generic classifier via a dependency with a stereotype of <<bind>>, and acts as the parent of the specialized classifier, which is connected to it by a generalization.

In the example below, SpecializedClass inherits from GenericClass via GenericClass_Bound, which specifies type parameters for the generic types T, T_2, and T_3.

At compile time, the specialized classifier can inherit the methods and properties of the generic classifier, and the generic type variables will be replaced by actual types. As a result, the compiler will be able to provide stronger type checking and automatic casting of the associated return values.

Creating a Bound Classifier

You may need to bind a classifier to a generic classifier without creating a specialized classifier. The Bound Classifier Wizard can do this for you.

1. Right-click a generic class or interface, and select Create Bound Class (or Interface) from the contextual menu to launch the Bound Classifier Wizard.
2. The wizard will create the bound classifier, which is attached to the generic classifier via a dependency with a stereotype of <<bind>>.

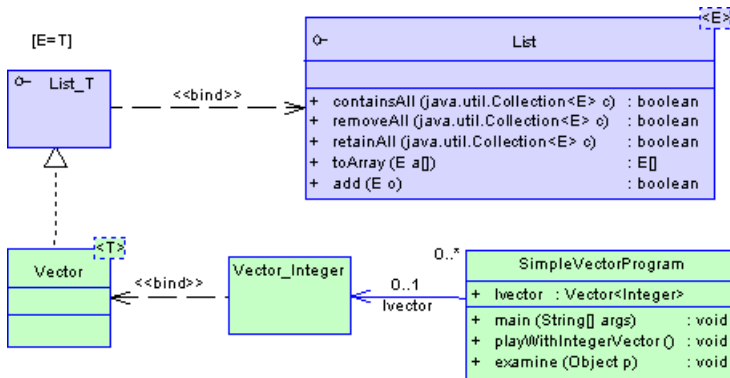

Generic Type Example

In the example below, the bound interface, List_T, specifies a type 'T' for the type parameter <E> of List.

The generic class Vector<T> realizes the generic interface List<E> (via the bound interface List_T) with a type <T> (that is defined in its own generic definition):

```
public class vector <T> implements List <E>
```

The bound class Vector_Integer specifies a type 'Integer' for the type parameter <T> of Vector<T>. The SimpleVectorProgram class is associated to Vector_Integer, allowing it to use the attribute data type of the Vector class set to Integer.

You must create a bound class for a generalization or a realization. However, we could have specified a parameter value for the generic type <T> directly (without creating a bound class) as an attribute data type, parameter data type, or return data type, by simply typing the following expression in the type field of SimpleVectorProgram:

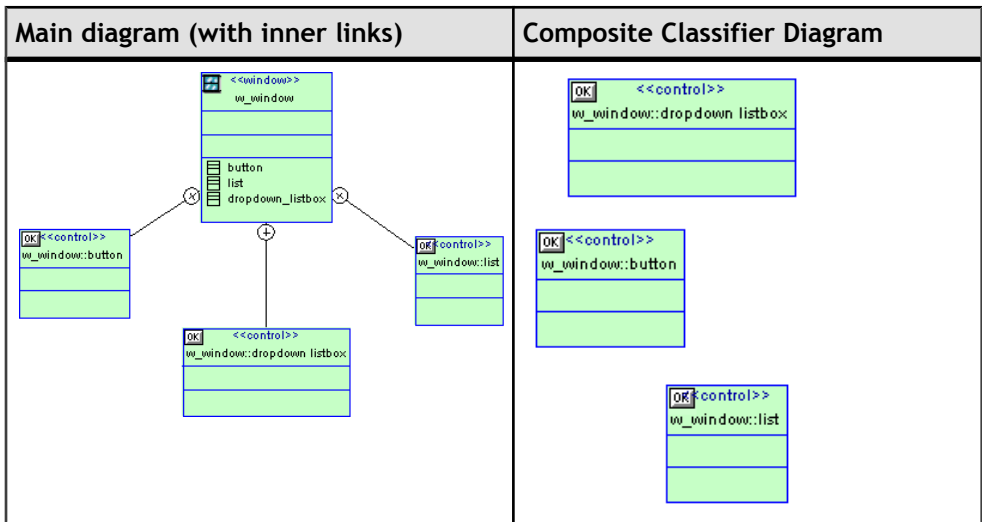

```
Vector<integer>
```

Composite and Inner Classifiers

A composite classifier is a class or an interface that contains other classes or interfaces (called inner classifiers). Inner classifiers are listed in the Browser as children of their composite classifier:

Inner classifiers can be displayed directly in the main class diagram, or in a additional class diagram specific to the composite classifier:

Note: You can display multiple composite classifiers in a composite structure diagram (see *Composite Structure Diagram Basics* on page 24).

Note: In previous versions of PowerDesigner, there was no composite classifier and inner classifiers used to appear at the same hierarchical level as their parent in the Browser tree view and in the list of classifiers.

Creating Inner Classifiers

You can create inner classifiers in a class or interface in any of the following ways:

- Open the Inner Classifiers tab in the property sheet of a class or interface, and click the Add inner class or Add inner interface tool.
- Right-click a class or interface in the Browser, and select **New > Class** or **New > Interface**
- Select the Inner Link tool in the Palette and click and use it to connect two classes in the diagram. The first class will become a composite class and the second, an inner classifier
- Create a composite classifier diagram dedicated to the class (see following section), and create classes or interfaces there.

All inner classifiers are listed in the bottom of the class symbol

Creating a Composite Classifier Diagram

You may want to create a diagram to show the internal structure of a composite classifier. You can create a composite classifier diagram in any of the following ways:

- Right-click a class or interface in the Browser, and select **New > Class Diagram**
- Double-click a class or interface in the diagram while holding down the CTRL key

The composite classifier diagram will be empty by default, even if the composite classifier already includes some inner classifiers. You can create symbols for the internal classifiers by

selecting **Symbol > Show Symbols**, or by dragging and dropping them from the Browser to the diagram.

If you have created a composite classifier diagram, you can display it in the main class diagram by right-clicking the class symbol and selecting **Composite View > Read-only (Sub-Diagram)**.

Attaching a Classifier to a Data Type or a Return Type

A data type or a return type can be a classifier. You can choose to attach a class, an interface, or a classifier from a JDK library for example, to the following objects:

- Attribute data type
- Operation return type
- Parameter data type

The classifier can belong to the current model or to another model. If it belongs to the current model or package, it is displayed by default together with the other classifiers of the current package. If it belongs to another model or package, a shortcut of the classifier is automatically created in the current package.

Fully Qualified Name

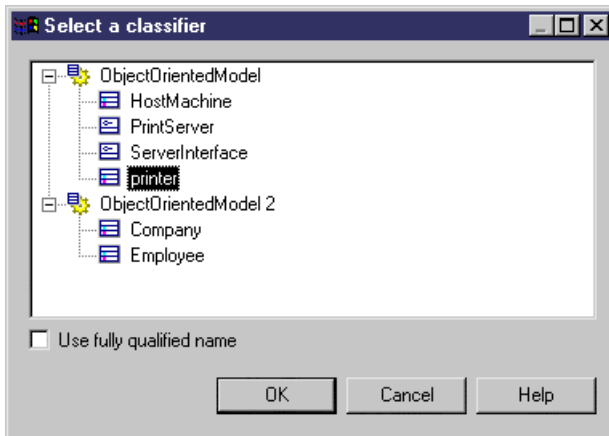

If the classifier belongs to another package of the same model, you can manually attach the classifier to a data type or return type by typing the fully qualified name of the classifier directly in the data type or return type box.

For example, if you need to reference `Class_2` as a classifier data type of an attribute named `Attr_1` in `Class_1`, open the `Attr_1` property sheet and type `PACKAGE_2.CLASS_2` in the Data type list.

- Package_1
- |__ Class_1
- |__ Attr_1
- Package_2
- |__ Class_2

After you type the fully qualified name (path and classifier name), it is displayed in the data type or return type box.

When a data type or a return type is created, there is no classifier attached to it, that is why the Use fully qualified name check box is not selected in the Select a Classifier dialog box.

However if you type a relative name, like 'Lang.Integer' instead of 'Java.Lang.Integer', the Use fully qualified name check box is automatically selected because a fully qualified name corresponds to this name.

Attaching a Classifier

To attach a classifier:

1. Double-click a class in the diagram to display its property sheet.
 - To attach a classifier to an attribute data type, click the Attributes tab, select an attribute in the list, and click the Properties tool to open the attribute property sheet.
 - To attach a classifier to an operation return type, click the Operations tab, select an operation in the list, and click the Properties tool to open the operation property sheet.
 - To attach a classifier to an operation parameter data type, click the Operations tab, select an operation in the list, and click the Properties tool to open the operation property sheet. Then click the Parameters tab, select a parameter in the list, and click the Properties tool to open the parameter property sheet
2. Click the Select a Classifier button beside the Data type listbox to open the Selection window. This window contains a list of all the classifiers in the model.
3. Select the classifier to be attached and click OK to return to the property sheet. The classifier name is now displayed in the Data type list.
4. Click OK.

Note: When you select a data type that matches the code of a classifier, the data type is automatically synchronized if the code of the classifier changes.

Viewing the Migrated Attributes of a Class

Navigable associations migrate attributes to classes during code generation. You can display these migrated attributes in the Associations tab of a class property sheet.

In the following example, the class Employee is associated with the class Company.

If you preview the generated code of the class `Employee`, you can see the following three attributes (in Java language):

```

public class EMPLOYEE
{
    public COMPANY hires[];
    public int NAME;
    public int DEPARTMENT;
}
  
```

The association between `Employee` and `Company` is migrated as the attribute `public COMPANY hires []`.

You can use the Associations tab of a class property sheet to display the list of all migrated attributes proceeding from navigable associations.

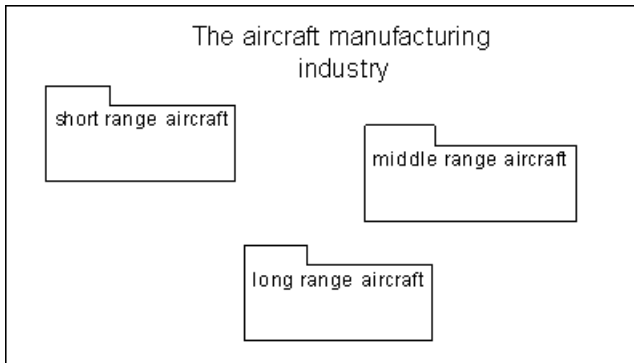

Inherited Associations

When a class inherits from a parent class through a generalization link, you can use the list of Inherited Associations to view the list of migrated attributes from the parent of the current class.

For example, the class `Developer` inherits from `Employee` through a generalization.

If you double-click the class `Developer`, click the Associations tab in the class property sheet and click the Inherited button, the list of Inherited Associations displays the migrated attribute of the class `Employee`.

Package Hierarchy

You can create several packages at the same hierarchical level within a model or decompose a package into other packages and continue this process without limitation in decomposition depth. Each package is displayed with a default diagram window. At each level of decomposition you can create several diagrams.

However, in an activity or statechart diagram, it is not possible to create a package in a composite activity or composite state since those ones are behaving like a package.

For more information on packages, see "Packages" in the Models chapter of the *Core Features Guide*.

Composite View

You can expand a package to have a global view of the whole diagram content by right-clicking a package and select **Composite View > Read-only (Sub-Diagram)**. You must resize the composite package symbol to visualize its content:

To return to the package normal view, right-click the symbol and select **Composite View > None**.

Note that if you double-click the composite view, you automatically open the sub-package diagram.

For more information on the composite view feature, see "Displaying the sub-diagram of a decomposed object within its symbol" in the Diagrams and Symbols chapter of the *Core Features Guide*.

```

Workspace
|- Model
   |- Diagram
   |- Package
      |- Diagram
      |- Diagram
      |- Package
         |- Diagram
   |- Package
   |- Diagram

```

You can create any type of diagrams in a package, or in a model. You use packages to organize your objects into functional or organizational domains.

If you delete a package, you also delete the diagrams and the objects it contains.

Objects created in a model or a package are shared between the diagrams of same type created in the same model or package.

OOM Package Properties

Packages have properties displayed on property sheets. All packages share the following common properties:

Property	Description
Name	Name that clearly identifies the package
Code	Codes are references for packages
Comment	Optional label that describes a package and provides additional information

Property	Description
Stereotype	<p>Sub-classification derived from an existing package. The following stereotypes are available by default:</p> <ul style="list-style-type: none"> • <<archive>> Jar or War archive (Java only) • <<assembly>> – Specifies that a package produces a portable executable (PE), (C# and VB.NET only) • <<CORBAModule>> – UML Package identified as IDL module (IDL-CORBA only) • <<facade>> – Package is a view of another package • <<framework>> – Package consists mostly of patterns • <<metamodel>> – Package is an abstraction of another package • <<model>> – Specifies a semantically closed abstraction of a system • <<stub>> – Package serves as a proxy for the public contents of another package • <<subsystem>> – Grouping of elements, some of which constitute a specification of the behavior offered by the other contained elements • <<system>> – Package represents the entire system being modeled • <<systemModel>> – Package that contains other packages with the same physical system. It also contains all relationships and constraints between model elements contained in different models • <<topLevel>> – Indicates the top-most package in a containment hierarchy
Use parent namespace	Defines the package as being the area in which the name of an object must be unique in order to be used
Default diagram	Diagram displayed by default when opening the package

Previewing the Code of a Package in an OOM

You can preview the code of a model or package in order to see the generated code, by clicking the Preview tab. The displayed code changes according to the object language you have selected in your model.

Defining the Diagram Type of a New Package

When you create a new package, the default diagram of the package is defined according to the following parameters:

- If you create a package using the Package tool from the palette, the diagram is of the same type as the parent package or model.
- If you create a package from the Browser, the diagram is of the same type as existing diagrams in the parent package or model, if these diagrams share the same type. If diagrams in the parent package or model are of different types, you are asked to select the type of diagram for the new sub-package.

- If you create a package from the List of Packages, the diagram is of the same type as the active diagram.

Interfaces (OOM)

An interface is similar to a class but it is used to define the specification of a behavior. It is a collection of operations specifying the externally visible behavior of a class. It has no implementation of its own.

An interface can be created in the following diagrams:

- Class Diagram
- Composite Structure Diagram
- Component Diagram

An interface includes the signatures of the operations. It specifies only a limited part of the behavior of a class. A class can implement one or more interfaces.

A class must implement all the operations in an interface to realize the interface. The following example shows an interface (Designated) realized by a class (Employee).

Creating an Interface

You can create an interface in any of the following ways:

- Select the Interface tool in the diagram Palette
- Select **Model > Interfaces** to access the List of Interfaces, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Interface**
- Right-click a class, and select Create Interface from the contextual menu (this method allows you to inherit all the operations of the class, including the getter and setter operations, creates a realization link between the interface and the class, and shows this link in the Realizes sub-tab of the Dependencies tab of the interface property sheet).

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Interface Properties

You can modify an object's properties from its property sheet. To open an interface property sheet, double-click its diagram symbol or its Browser entry in the Interfaces folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	<p>Extends the semantics of the object beyond the core UML definition. The following common stereotypes are available by default:</p> <ul style="list-style-type: none"> • <<metaclass>> - interface that will interact with a model that contains classes with metaclass stereotypes • <<powertype>> - a metaclass whose instances are sub-classes of another class • <<process>> - heavyweight flow that can execute concurrently with other processes • <<thread>> - lightweight flow that can execute concurrently with other threads within the same process. Usually executes inside the address space of an enclosing process • <<utility>> - a class that has no instances
Visibility	<p>Specifies the visibility of the object, how it is seen outside its enclosing namespace. When an interface is visible to another object, it may influence the structure or behavior of the object, or similarly, the other object can affect the properties of the interface. You can choose between:</p> <ul style="list-style-type: none"> • Private – only to the object itself • Protected – only to the object and its inherited objects • Package – to all objects contained within the same package • Public – to all objects (option by default)
Inner to	Indicates the name of the class or interface to which the current interface belongs as an inner classifier

Property	Description
Type	<p>Allows you to specify that an interface is a generic type, or that it is bound to one. You can choose between:</p> <ul style="list-style-type: none"> • Interface • Generic • Bound – If you select this option, then an additional list becomes available to the right, where you can specify the generic type to which the interface is bound. <p>If you specify either Generic or Bound, then the Generic tab is displayed, allowing you to control the associated type variables (see <i>Interface property sheet Generic tab</i> on page 54). For more information on generic types and binding interfaces to them, see <i>Generic types and methods</i> on page 40.</p>
Generate	<p>The interface is automatically included among the objects generated from the model when you launch the generation process</p>

The following tabs list objects associated with the interface:

- **Attributes** - lists the attributes associated with the interface. You can create attributes directly in this page, or add already existing attributes. For more information, see *Attributes (OOM)* on page 65.
- **Operations** - lists the operations associated with the interface. You can create operations directly in this page, or add already existing operations. For more information, see *Operations (OOM)* on page 76.
- **Inner Classifiers** - lists the inner classes and interfaces associated with the interface. You can create inner classifiers directly in this page. For more information, see *Composite and inner classifiers* on page 43.
- **Related Diagrams** - lists the model diagrams that are related to the interface. You can add diagrams in this page. For more information, see "Defining related diagrams" in the *Diagrams and Symbols* chapter of the *Core Features Guide*.

Interface Property Sheet Generic Tab

The Generic tab allows you to specify either:

- That the interface is a generic type, and to list its type parameters, or
- That the interface is bound to a generic type, and to give values for the required type parameters

For more information, see *Generic types and methods* on page 40.

Objects (OOM)

At the conceptual level, an *object* is an element defined as being part of the system described. It represents an object that has not yet been instantiated because the classes are not yet clearly defined at this stage.

If you need to go further with the implementation of your model, the object that has emerged during analysis will probably turn into an instance of a defined class. In this case, an object is considered an instance of a class.

Three possible situations can be represented:

- When an object is not an instance of a class - it has only a name
- When an object is an instance of a class - it has a name and a class
- When an object is an instance of a class but is actually representing any or all instances of a class - it has a class but no name

An object can be created in the following diagrams:

- Communication Diagram
- Object Diagram
- Sequence Diagram

The object shares the same concept in the object, sequence and communication diagrams. It can either be created in the diagram type you need, or dragged from a diagram type and dropped into another diagram type.

Defining Multiples

A *multiple* defines a set of instances. It is a graphical representation of an object that represents several instances, however a multiple can only hold one set of attributes even if it represents several instances. An object can communicate with another object that is a multiple. This feature is mainly used in the communication diagram but can also be used in the object diagram.

A clerk handles a list of documents: it is the list of documents that represents a multiple object.

When the Multiple check box is selected in the object property sheet, a specific symbol (two superposed rectangles) is displayed.

Objects in an Object Diagram

In the object diagram, an object instance of a class can display the values of attributes defined on the class. When the class is deleted, the associated objects are not deleted.

Objects in a Communication Diagram

In a communication diagram, an *object* is an instance of a class. It can be persistent or transient: persistent is the situation of an object that continues to exist after the process that created it has finished, and transient is the situation of an object that stops to exist when the process that created it finishes.

The name of the object is displayed underlined. The Underline character traditionally indicates that an element is an instance of another element.

Objects in a Sequence Diagram

In the sequence diagram, an object has a *lifeline*: it is the dashed vertical line under the object symbol. Time always proceeds down the page. The object lifeline indicates the period during which an object exists. You cannot separate an object and its lifeline.

If the object is created or destroyed during the period of time shown on the diagram, then its lifeline starts or stops at the corresponding point.

Objects appear at the top of the diagram. They exchange messages between them.

An object that exists when a transaction, or message starts, is shown at the top of the diagram, above the first message arrow. The lifeline of an object that still exists when the transaction is over, continues beyond the final message arrow.

Creating an Object

To create an object:

- Select the Object tool in the diagram Palette
- Select **Model > Objects** to access the List of Objects, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Object**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Object Properties

You can modify an object's properties from its property sheet. To open an object property sheet, double-click its diagram symbol or its Browser entry in the Objects folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users. Not compulsory since you can have an object representing an unnamed instance of a class or interface, but if omitted, you need to supply the class or interface name in the Classifier box. The name should be unique per class or interface. Two objects could share the same name only if they belong to two different classes or interfaces.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Classifier	Specifies the class or interface of which an object is an instance. You can link an object to an existing class or interface, or create a new one using the Create Class button beside this box. For more information, see <i>Linking a class or interface to an object</i> on page 59.
Multiple	Object that represents several instances

Object Property Sheet Attribute Values Tab

When an object is an instance of a class, the attributes of the class can be added to the object from the Attribute Values tab in the object property sheet. Once the attribute is added, you can attach a value to the attribute from this same tab.

When you add a value to the attribute, the attribute property sheet displays this information in the Attribute Values tabbed page of the Dependencies tab.

An attribute value represents an instance of a class attribute. It refers to an attribute of the class from which the current object is an instance, or it can refer to an attribute inherited from a parent of the class. An attribute value is stored as text.

An attribute value is created when you assign a value to an attribute. There is no symbol of attribute value, there is no property sheet either.

You access attribute values from the Attribute Values tab in the object property sheet. An Add Attribute Values tool allows you to add attributes to this tab. The Add Attribute Values tool opens a selection dialog box that displays all attributes of the class of the object, including inherited attributes of classes from which the class inherits (also known as *super classes*). Once the attribute is added to the object, it is possible to define its value from the Value column in the list.

There is only *one* attribute value per attribute (attribute of the class of the object). Attribute values are displayed within the object symbol in the object diagram, if they are not displayed, you should modify the object display preferences.

PC:Computer	
OS	= Win2000
name	= Dev_lab

You can assign a value to a migrated attribute.

You can not create shortcuts of attribute values, neither move nor copy attribute values. For all external shortcuts of objects, the list of attribute values is displayed only when the model containing the shortcut of the object is loaded in the workspace.

Attribute Values Behavior

When an attribute value is assigned to an object, it is associated with this object and the attribute must belong to the class of the object or to one of its inherited class.

The coherence between the class of the object, the attribute, and the attribute value is handled in PowerDesigner. For example when you change the inheritance, the attribute value on the corresponding object is automatically removed if the attribute value is not associated with attributes owned by the new class, or by its super classes.

The coherence between the order of attributes in the class and the order of attribute values is not handled. This allows you to sort the attribute values according to your needs.

The following rules apply to attribute values:

- When the class from which the object is an instance is an external shortcut, the attribute values of this object must be updated if the attributes of the class, or of the super classes have been modified, deleted, added or their data type changed. You have to update them

after the model containing the class, or the model containing the object is loaded in the workspace

- When you remove an attribute, its corresponding attribute value is removed

An attribute value has no property sheet of its own. All properties displayed in the Attribute Values tab of the object property sheet are calculated, read-only properties that are duplicated from the attribute. The only property that is not read-only is the Value property that you must type or select in order to create the attribute value.

Property	Description
Class	Class of the object. You can select the Ellipsis button in the Class column to display the class property sheet
Attribute	Attribute of the class of the object. You can select the Ellipsis button in the Attribute column to display the attribute property sheet
Value	Value of the attribute. You can type your own value, or select the down arrow and choose a value from the list. This list comes from the List of Values groupbox in the Standard Checks tab of the attribute property sheet. If you use multi-valued attributes, you can use the syntax of your choice to type the values in this column
Data type	Data type of the attribute
Initial value	Initial value of the attribute (including quotes if needed)
Primary identifier	If selected, indicates that the attribute is part of a primary identifier For more information on primary identifiers, see <i>Identifiers (OOM)</i> on page 73.

Linking a Classifier to an Object

The object diagram represents instances of class or interface, the sequence diagram represents the dynamic behavior of a class or interface, and the communication diagram represents those instances in a communication mode. For all these reasons, you can link a class or an interface to an object in an OOM.

From the object property sheet, you can:

- Link the object to an existing class or interface
 - Create a class
1. Select a class or interface from the Classifier list in the object property sheet.

or

Click the Create Class tool beside the Classifier list to create a class and display its property sheet.

Define the properties of the new class and click OK.

The class or interface name is displayed in the Classifier list.

2. Click OK.

The object name is displayed in the sequence diagram, followed by a colon, and the name of the class or interface selected.

You can similarly view the object name in the class or interface property sheet: click the Dependencies tab and select the Objects sub-tab. The object name is automatically added in this sub-tab.

Note: You can drag a class or interface node from the Browser and drop it into the sequence, communication or object diagrams. You can also copy a class or interface and paste it, or paste it as shortcut, into these diagrams. This automatically creates an object, instance of the class or of the interface.

Parts (OOM)

A part allows you to define a discrete area inside a class or a component. Parts can be connected to other parts or to ports, either directly or via a port on the outside of the part.

You connect a part to another part by way of an assembly connector. You connect a part to a port on the outside of a class or component by way of a delegation connector.

A part can be created in the following diagrams:

- Composite Structure Diagram (inside a class)
- Component Diagram (inside a component)

You can only create a part within a class or a component. If you attempt to drag a part outside of its enclosing classifier, the classifier will grow to continue to enclose it.

Parts in a Composite Structure Diagram

In the example below, the class TitleImpl2 contains a part called unitTest

Parts in a Component Diagram

In the example below, the component `PersistentTitle` contains two parts, `TitleManager` and `TitleDataAccess`

Creating a Part

You can create a part in any of the following ways:

- Use the Part tool in the diagram Palette
- Open the Parts tab in the property sheet of a class or component, and click the Add a Row tool

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Part Properties

You can modify an object's properties from its property sheet. To open a part property sheet, double-click its diagram symbol or its entry in the Browser.

The General tab contains the following properties:

Property	Description
Parent	Specifies the parent object.
Name	The name of the item which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Visibility	Specifies the visibility of the object, how it is seen outside its enclosing namespace. You can choose between: <ul style="list-style-type: none"> • Private – only to the object itself • Protected – only to the object and its inherited objects • Package – to all objects contained within the same package • Public – to all objects (option by default)
Data type	Specifies a classifier as a data type.

Property	Description
Multiplicity	<p>Specifies the number of instances of the part. If the multiplicity is a range of values, it means that the number of parts can vary at run time.</p> <p>You can choose between:</p> <ul style="list-style-type: none"> • * – none to unlimited • 0..* – zero to unlimited • 0..1 – zero or one • 1..* – one to unlimited • 1..1 – exactly one
Composition	<p>Specifies the nature of the association with the parent object. If this option is selected, it is a composition and if not, an aggregation.</p>

The following tabs list objects associated with the part:

- Ports - lists the ports associated with the part. You can create ports directly in this tab. For more information, see *Ports (OOM)* on page 62.

Ports (OOM)

A port is created on the outside of a classifier and specifies a distinct interaction point between the classifier and its environment or between the (behavior of the) classifier and its internal parts.

Ports can be connected to:

- a part via a delegation connector, through which requests can be made to invoke the behavioral features of a classifier
- an interface via a require link, through which the port may specify the services a classifier provides (offers) to its environment as well as the services that a classifier expects (requires) of its environment.

A port can be created in the following diagrams:

- Class Diagram (on a class)
- Composite Structure Diagram (on a class, a part, or an interface)
- Component Diagram (on a component or a part)

Ports in a Class Diagram

In the example below, the class TitleImpl2 contains the ports sql and stat, which are connected by require links to the interfaces java.math.stat2 and java.sql.connection2:

Ports in a Composite Structure Diagram

In the example below, the internal structure of the class `TitleImpl2` is shown in more detail, and demonstrates how ports can be used to specify interaction points between a part and its enclosing classifier:

Ports in a Component Diagram

In the example below, the use of ports to connect parts with an enclosing component is demonstrated:

Creating a Port

You can create a port in any of the following ways:

- Use the Port tool in the diagram Palette
- Open the Ports tab in the property sheet of a class, part, or component, and click the Add a Row tool

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Port Properties

You can modify an object's properties from its property sheet. To open a port property sheet, double-click its diagram symbol or Browser entry. The following sections detail the property sheet tabs that contain the properties most commonly entered for ports.

The General tab contains the following properties:

Property	Description
Parent	Specifies the parent classifier.

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Visibility	Specifies the visibility of the object, how it is seen outside its enclosing namespace. You can choose between: <ul style="list-style-type: none"> • Private – only to the object itself • Protected – only to the object and its inherited objects • Package – to all objects contained within the same package • Public – (default) to all objects
Data type	Specifies a classifier as a data type.
Multiplicity	Specifies the number of instances of the port. If the multiplicity is a range of values, it means that the number of ports can vary at run time. <p>You can choose between:</p> <ul style="list-style-type: none"> • * – none to unlimited • 0..* – zero to unlimited • 0..1 – zero or one • 1..* – one to unlimited • 1..1 – exactly one
Redefines	A port may be redefined when its containing classifier is specialized. The redefining port may have additional interfaces to those that are associated with the redefined port or it may replace an interface by one of its subtypes.
Is Service	Specifies that this port is used to provide the published functionality of a classifier (default). <p>If this property is cleared, the port is used to implement the classifier but is not part of the essential externally-visible functionality of the classifier. It can, therefore, be altered or deleted along with the internal implementation of the classifier and other properties that are considered part of its implementation.</p>
Is Behavior	Specifies that the port is a "behavior port", and that requests arriving at this port are sent to the classifier behavior of the classifier. Any invocation of a behavioral feature targeted at a behavior port will be handled by the instance of the owning classifier itself, rather than by any instances that this classifier may contain.

Redefining Parent Ports

A classifier that is connected to a parent by way of a generalization can redefine the ports of the parent.

1. Open the property sheet of a class, interface, or component, and click the Ports tab.
2. Click the Redefine button at the bottom of the tab to open the Parent Ports window, which will display a list of ports belonging to the parent classifier.

1. Select a port and then click Redefine to have it redefined by the child classifier.
2. Click Close to return to the child's property sheet. The redefined port will now appear in the list on the Ports tab.

Attributes (OOM)

An attribute is a named property of a class (or an interface) describing its characteristics.

An attribute can be created for a class or interface in the following diagrams:

- Class Diagram
- Composite Structure Diagram
- Component Diagram

A class or an interface may have none or several attributes. Each object in a class has the same attributes, but the values of the attributes may be different.

Attribute names within a class must be unique. You can give identical names to two or more attributes only if they exist in different classes.

In the following example, the class Printer contains two attributes: printspeed and laser:

Printer	
+	printspeed : int
+	laser : boolean

Interface Attributes

An attribute of an interface is slightly different from an attribute of a class because an interface can only have constant attributes (static and frozen). For example, consider an interface named Color with three attributes RED, GREEN, and BLUE. They are all static, final and frozen.

Color	
+	RED : int = 0xFF0000
+	GREEN : int = 0x00FF00
+	BLUE : int = 0x0000FF

If you generate in Java, you see:

```
public interface Color
{
    public static final int RED = 0xFF0000;
    public static final int GREEN = 0x00FF00;
    public static final int BLUE = 0x0000FF;
}
```

All these attributes are constants because they are static (independent from the instances), final (they can not be overloaded), and frozen (their value cannot be changed).

You can use the attributes of other interfaces or classes and add them to the current interface.

Creating an Attribute

You can create an attribute as follows:

- Open the Attributes tab in the property sheet of a class, identifier, or interface, and click the Add a Row tool

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Attribute Properties

You can modify an object's properties from its property sheet. To open an attribute property sheet, double-click its Browser entry in the Attributes folder.

The General tab contains the following properties:

Property	Description
Parent	To which the attribute belongs

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Visibility	<p>Specifies the visibility of the object, how it is seen outside its enclosing namespace. When a class is visible to another object, it may influence the structure or behavior of the object, or similarly, the other object can affect the properties of the class. You can choose between:</p> <ul style="list-style-type: none"> • Private – only to the class to which it belongs • Protected – only to the class and its derived objects • Package – to all objects contained within the same package • Public – to all objects (option by default)
Data type	Set of instances sharing the same operations, abstract attributes, relationships, and semantics
Multiplicity	<p>Specifies the range of allowable number of values the attribute may hold. You can choose between:</p> <ul style="list-style-type: none"> • 0..1 – zero or one • 0.* – zero to unlimited • 1..1 – exactly one • 1.* – one to unlimited • * – none to unlimited <p>You can change the default format of multiplicity from the registry.</p> <pre>HKEY_CURRENT_USER\Software\Sybase\PowerDesigner 12\ModelOptions\Cld MultiplicityNotation = 1 (0..1) or 2 (0,1)</pre>
Array size	<p>Specifies multiplicity in the syntax of a given language, when attribute multiplicity cannot express it. For example, you can set array size to [4,6,8] to get the PowerBuilder syntax <code>int n[4,6,8]</code> or set array size to [,] to get the c# syntax <code>int[,]</code> n;</p> <p>Depending on the model language, the following will be generated:</p> <ul style="list-style-type: none"> • Java, C# and C++ – [2][4][6] • PowerBuilder – [2,4,6] • VB .NET – (2,4,6)

Property	Description
Enum class	[For Java 5.0 only] Specifies an anonymous class for an EnumConstant. To create the class, click the Create tool to the right of this property. To open the property sheet of this anonymous class, click the Properties tool. To delete it, click the Delete tool.
Static	The attribute is associated with the class, as a consequence, static attributes are shared by all instances of the class and have always the same value among instances
Derived	Indicates that the attribute can be computed from another attribute. The derivation formula can be defined in the attribute description tab, it does not influence code generation
Mandatory	Boolean calculated attribute selected if the minimum multiplicity is greater than 0
Volatile	Indicates that the attribute is not a member of the class. It is only defined by getter and setter operations, in C# it replaces the former extended attribute volatile

For more information on adding operations to a class, see *Adding Getter and Setter operations to a classifier* on page 69.

Attribute Property Sheet Detail Tab

The Detail tab contains a Persistent groupbox whose purpose is to improve the generation of code and data types during generation of a CDM or a PDM from an OOM.

The complete list of options on this tab is as follows:

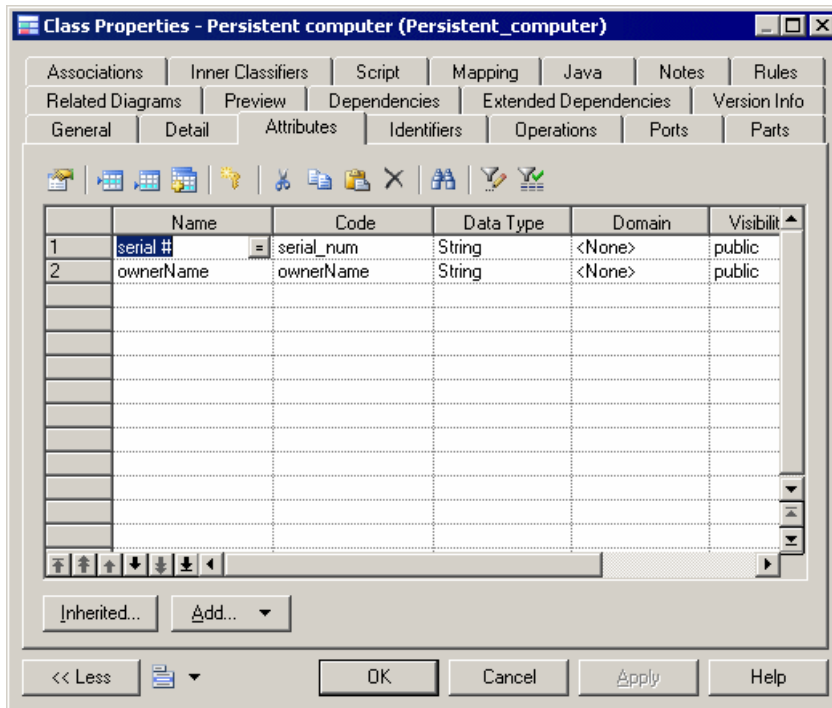

Property	Description
Changeability	Specifies if the value of the attribute can be modified once the object has been initialized. You can choose between: <ul style="list-style-type: none"> • Changeable – The value can be changed • Read-only – Prevents the creation of a setter operation (a setter is created in the method inside the class) • Frozen – Constant • Add-only – Allows you to add a new value only
Domain	Specifies an associated domain. If you attach an attribute to a domain, the domain supplies the data type and related data characteristics. It may also indicate check parameters, and business rules. Select a domain from the list, or click the List button to the right of the list to create a new domain in the List of Domains.
Primary Identifier	If selected, indicates that the current attribute is part of a primary identifier. Primary identifiers are converted to primary keys after generation of an OOM to a PDM. Exists only in classes

Property	Description
Migrated from	Contains the association name that is at the origin of creation of the attribute. You can click the Properties tool beside this box to display the association property sheet. For more information on migrating attributes, see <i>Migrating association roles in a class diagram</i> on page 95.
Persistent	Groupbox for valid generation of CDM or PDM persistent models. Available only for class attributes (it is not applicable to interface attributes). For more information on object persistence, see <i>Managing Object Persistence During OOM to PDM Generation</i> on page 292.
Code	Specifies the code of the table or entity that will be generated in a persistent CDM or PDM model.
Data type	Specifies a persistent data type used in the generation of a persistent model, either CDM or PDM. The persistent data type is defined from default PowerDesigner conceptual data types
Length	Maximum number of characters of the persistent data type
Precision	Number of places after the decimal point, for persistent data type values that can take a decimal point
Overrides	[PowerBuilder only] Indicates which parent attribute the current attribute is overriding through a generalization link

Adding Getter and Setter Operations to a Classifier

PowerDesigner helps you to quickly create Getter and Setter operations for your attributes from the **Attributes** tab of your classifier.

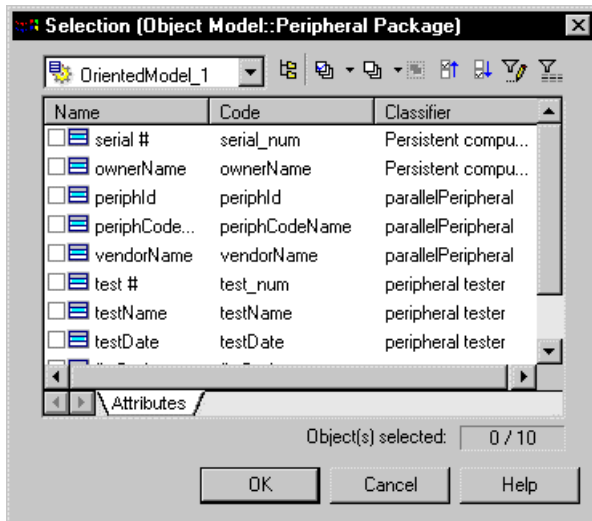

1. Open the property sheet of your classifier and click the **Attributes** tab.

2. Select one or more attributes and then click the **Add** button at the bottom of the attributes tab and select the action you want to perform. Depending on the target language, some of the following actions will be available:
 - Get/Set Operations - Creates get and set operations on the **Operations tab** for the selected attributes
 - Property - [C#/VB.NET only] Creates a property on the **Attributes tab** and get and set operations on the **Operations tab** to access the original attribute via the property.
 - Indexer - [C# only] Creates an indexer on the **Attributes tab** and get and set operations on the **Operations tab** to access the original attribute via the indexer.
 - Event Operations - [C#/VB.NET only, for attributes with the Event stereotype] Creates add and remove operations on the **Operations tab** for the event.
3. [optional] Click the **Operations** tab to view the newly created operations. Certain values, including the names cannot be modified.
4. Click **OK** to close the property sheet and return to your model.

Copying an Attribute to a Class, Interface, or Identifier

You can duplicate an attribute from one classifier to another. If the classifier already contains an attribute with the same name or code as the copied attribute, the copied attribute is renamed.

3. Select the attributes you want to add to the object.

or

Use the Select All tool to add all the attributes in the list to the object.

4. Click OK to add the selected attributes to the current object.

Overriding an Attribute in PowerBuilder

The Inherited Attributes dialog box allows you to:

- View the attributes inherited from the parent classes or interfaces
- Override an attribute, this feature is only available in PowerBuilder

Within the context of an inheritance, you can add an attribute that belongs to a parent class to a child class. This is called overriding. The attribute of the parent class is said to be overridden when this attribute is redefined in a child class.

Once you add an attribute to a class, you can only modify the initial value of the attribute. You cannot modify other attribute properties.

Adding an Inherited Attribute to a Class

To add an inherited attribute to a class:

1. Double-click a class that is linked to a parent class in the diagram to open its property sheet, and then click the Attributes tab.
2. Click the Inherited button to open the Inherited Attribute window. This window lists all the attributes that belong to all the parent classes of the class.

3. Select an attribute and click Override and then Close. A copy of the attribute is added to the list of attributes of the child class. It is grayed to indicate that its properties cannot be modified, and its stereotype is set to <<Override>>.
4. Click OK.

Identifiers (OOM)

An identifier is a class attribute, or a combination of class attributes, whose values uniquely identify each occurrence of the class. It is used during intermodel generation when you generate a CDM or a PDM into an OOM, the CDM identifier and the PDM primary or alternate keys become identifiers in the OOM.

An identifier can be created for a class in the following diagrams:

- Class Diagram
- Composite Structure Diagram

Each class can have at least one identifier. Among identifiers, the primary identifier is the main identifier of the class. This identifier corresponds to a primary key in the PDM.

When you create an identifier, you can attach attributes or business rules to it. You can also define one or several attributes as being primary identifier of the class.

For example, the social security number for a class employee is the primary identifier of this class.

Creating an Identifier

You can create an identifier in any of the following ways:

- Open the Identifiers tab in the property sheet of a class or interface, and click the Add a Row tool

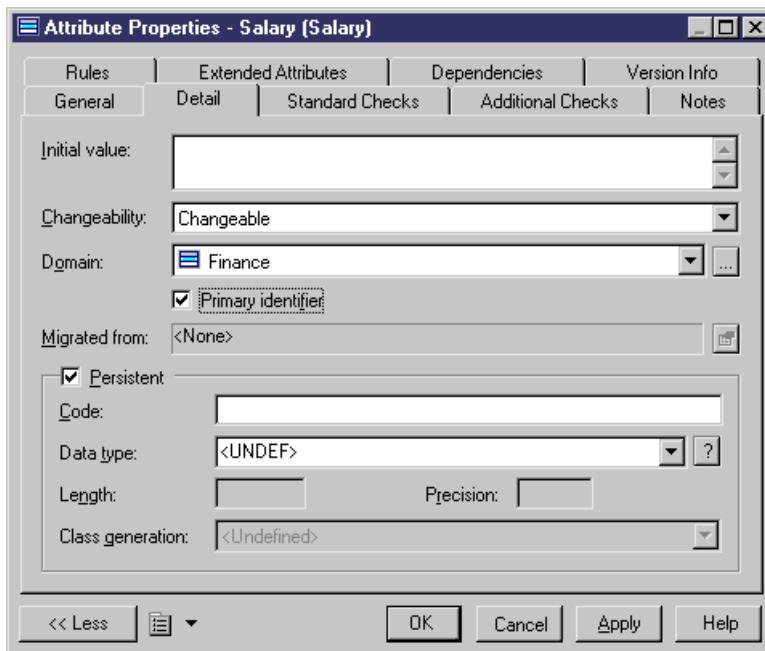

- Select the Primary Identifier checkbox when you create an attribute

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Creating a primary identifier when you create the class attributes

To Create a Primary Identifier when You Create the Class Attributes:

1. Double-click a class in the diagram to display its property sheet, and then click the Attributes tab.
2. Double-click an attribute in the list to display its property sheet, and then click the Detail tab.
3. Select the Primary Identifier check box and click OK to return to the Attributes tab of the class property sheet.

4. Click the Identifiers tab to view the new identifier in the list.
5. Click OK.

Defining the Primary Identifier from the List of Identifiers

To define the primary identifier from the List of Identifiers:

1. Select **Model > Identifiers** to display the list of identifiers.
2. Double-click an identifier in the list to display its property sheet.
3. Select the Primary Identifier check box.

- Click OK in each of the dialog boxes.

Identifier Properties

You can modify an object's properties from its property sheet. To open an identifier property sheet, double-click its Browser entry in the Identifiers folder.

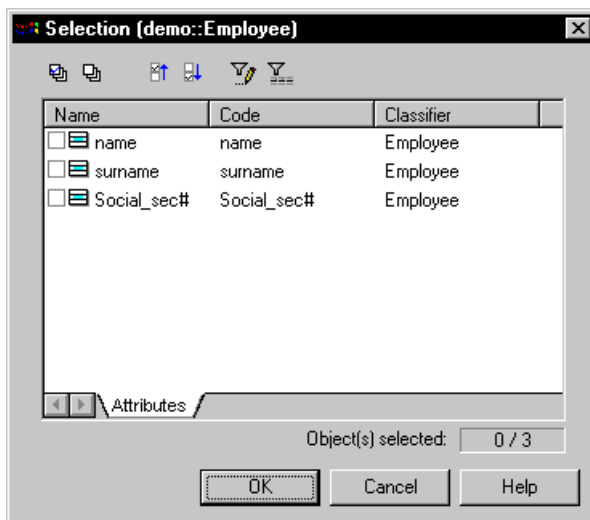

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Class	Specifies the class to which the identifier belongs.
Primary Identifier	Specifies that the identifier is a primary identifier.

Adding Attributes to an Identifier

An identifier can contain one or several attributes. You can add these attributes to an identifier to further characterize the identifier.

- Select an identifier from the List of Identifiers or the Identifiers tab in the property sheet of a class, and click the Properties tool to display its property sheet.
- Click the Attributes tab and click the Add Attributes tool to display the list of attributes for the class.

3. Select the check boxes for the attributes you want to add to the identifier.
4. Click OK in each of the dialog boxes.

Operations (OOM)

An operation is a named specification of a service that can be requested from any object of a class to affect behavior. It is a specification of a query that an object may be called to execute.

An operation can be created for a class or interface in the following diagrams:

- Class Diagram
- Composite Structure Diagram
- Component Diagram

A class may have any number of operations or no operations at all.

In the following example, the class Car, has 3 operations: start engine, brake, and accelerate.

Operations have a name and a list of parameters. Several operations can have the same name within the same class if their parameters are different.

For more information on *EJB operations*, see *Defining Operations for EJBs* on page 375.

Creating an Operation

You can create an operation as follows:

- Open the Operations tab in the property sheet of a class or interface, and click the Add a Row tool

You can create the following types of operation in a class or interface:

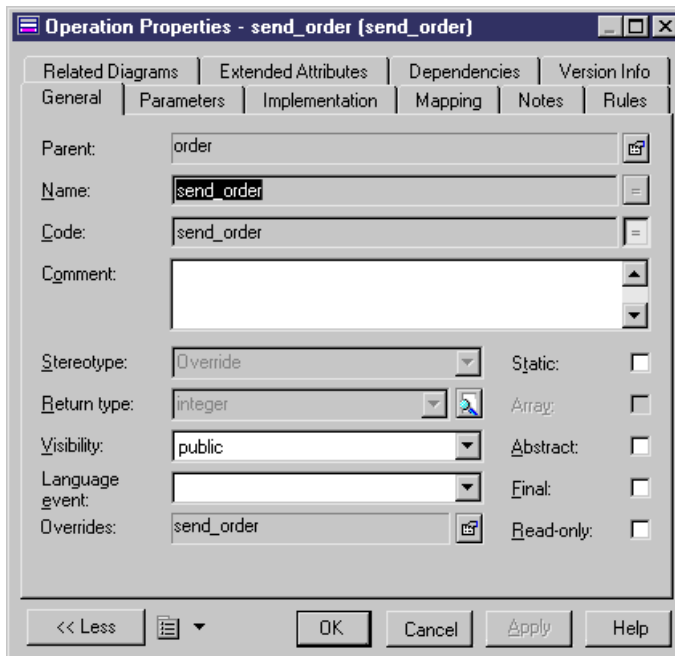

- Your own operations
- Operations inherited from a parent of the current class
- Standard operations such as constructors/destructors or initializers
- Operations to be implemented from an interface by which the current class is linked by a realization link

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Creating a User-Defined Operation

You can create your own operations from the **Operations** tab of a classifier.

1. Double-click a class or interface to display its property sheet, and then click the Operations tab.
2. Click the Add a Row tool to create a new operation.
3. Click the Properties tool and click Yes in the confirmation box to open the property sheet of the new operation.

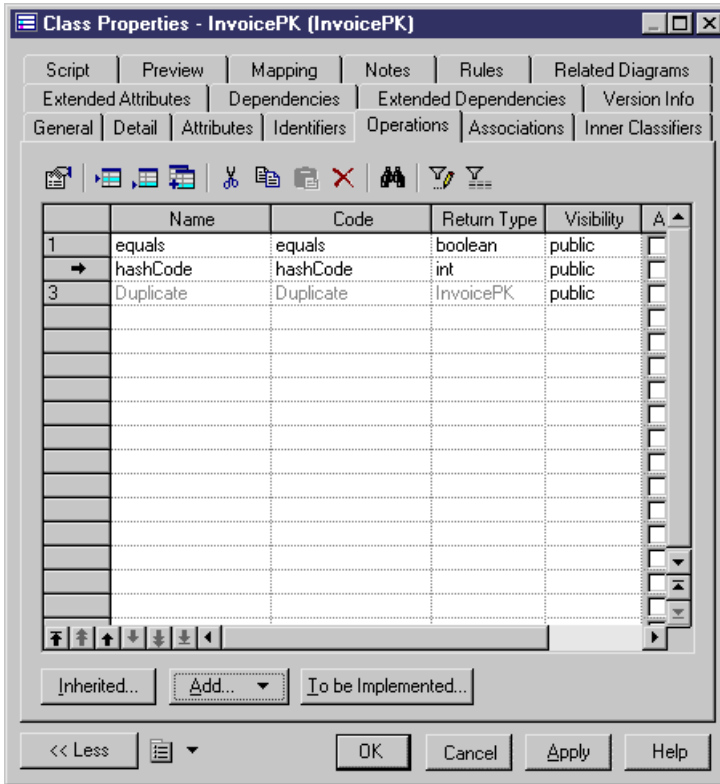

4. Enter any necessary properties and then click OK to complete the creation of the operation.

Creating a Standard Operation

PowerDesigner can create standard operations for your classifiers using tools on the classifier property sheet **Operations** tab.

1. Open the property sheet of your classifier and click the **Operations** tab.

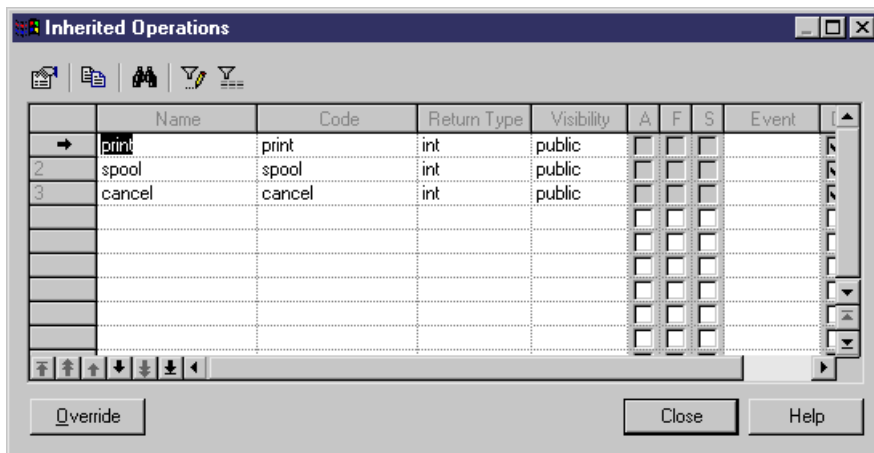

2. Click the **Add** button at the bottom of the tab, and select the type of standard operation you want to add. Depending on the target language, some of the following types of standard operations will be available:
 - *Default Constructor/Destructor*- to perform initialization/cleanup for classifiers. You can add parameters afterwards.
 - *Copy Constructor Operations* - to copy the attributes of a class instance to initialize another instance.
 - *Initializer/Static Initializer Operations*- [Java only] to initialize a class before any constructor.
 - *Duplicate Operations* - to create and initialize an instance of a class within the class.
 - *Activate/Deactivate Operations* - [PowerBuilder only]
 The operation is added to the list. Some or all of its properties will be dimmed to indicate that they are uneditable.
3. [optional] Select the operation and then click the **Properties** tool to add parameters to it or otherwise complete its definition.
4. Add other operations as necessary, or click **OK** to close the property sheet and return to your model.

Inheriting and Overriding Operations from Parent Classifiers

PowerDesigner lets you view and override operations inherited from parent classes from the child class property sheet **Operations** tab.

In order to inherit and be able to override inherited operations, your class must be linked to one or more parent classifiers that have operations specified.

1. Open the property sheet of a class that is linked by a generalization link to one or more parents and click the **Operations** tab.
2. Click the **Inherited** button to open the Inherited Operations window, which lists the operations that the classifier inherits from its parents:

3. Select one or more operations, and then click the **Override** button to copy them to the list of operations of the child class with their stereotype set to <<Override>>. Each overridden operation has the same signature (name and parameters) as the original operation, and you can only modify the code on its **Implementation** tab.
4. Click **Close** to return to the **Operations** tab, and then click **OK** to return to your model.

Creating an Implementation Operation

When you create a realization link between a class and an interface, the class must implement all the operations of the interface.

Note: To automatically create the necessary operations in your class, click **Tools > Model Options** to open the Model Options dialog, and select the **Auto-Implement Realized Interfaces** option. If this option is not selected, you can implement the operations manually.

1. Open the property sheet of a class that is linked to one or more interfaces by realization links and click the **Operations** tab.

2. Click the **To be Implemented** button to open the To Be Implemented Operations window, which lists all the operations waiting to be implemented in the class. You can use the Properties button to display the property sheet of an operation.

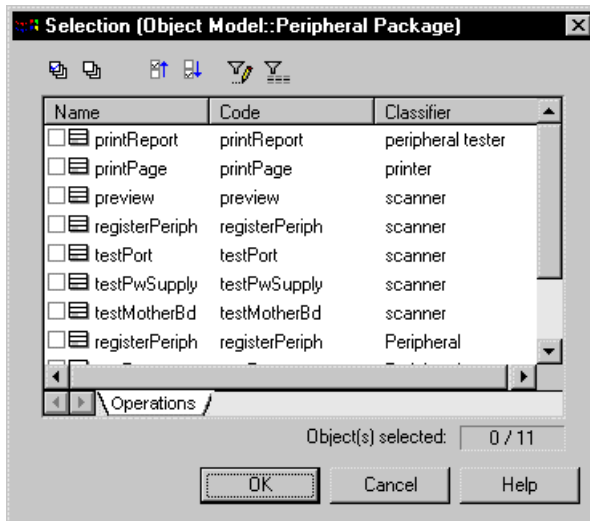

3. Select one or more operations, and then click the **Implement** button to copy them to the list of operations of the class with their stereotype set to <<Implement>>. Each implemented operation has the same signature (name and parameters) as the original operation, and you can only modify the code on its **Implementation** tab.
4. Click **Close** to return to the **Operations** tab, and then click **OK** to return to your model.

Copying an Operation to Another Class

You can copy an operation from one class and add it to another. If the class already contains an operation with the same name or code as the copied operation, the copied operation is renamed. For example the operation testPort is renamed testPort2 when it is copied to a class which already contains an operation testPort.

1. Double-click a class in the diagram to display its property sheet, and then click the Operations tab.
2. Click the Add Operations tool to open a Selection window. This window lists all the operations attached to all the classes in the model.

3. Select one or more operations in the list and then click OK to add the copied operations to the list of operations.
4. Click OK.

Operation Properties

You can modify an object's properties from its property sheet. To open an operation property sheet, double-click its Browser entry in the Operations folder.

The General tab contains the following properties:

Property	Description
Parent	To which the operation belongs
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.

Property	Description
Stereotype	<p>Extends the semantics of the object beyond the core UML definition. The following common stereotypes are available by default:</p> <ul style="list-style-type: none"> • <<constructor>> - Operation called during the instantiation of an object that creates an instance of a class • <<create>> - Operation used by a class when instantiating an object • <<destroy>> - Operation used by a class that destroys an instance of a class • <<storedProcedure>> - Operation will become a stored procedure in the generated PDM • <<storedFunction>> - Operation will become a stored function in the generated PDM • <<EJBCreateMethod>> - EJB specific CreateMethod • <<EJBFinderMethod>> - EJB specific FinderMethod • <<EJBSelectMethod>> - EJB specific SelectMethod <p>For more information on EJB specific methods, see <i>Defining Operations for EJBs</i> on page 375.</p>
Return Type	A list of values returned by a call of the operation. If none are returned, the return type value is null
Visibility	<p>Visibility of the operation, whose value denotes how it is seen outside its enclosing name space. Exists only in classes:</p> <ul style="list-style-type: none"> • Private - Only to the class to which it belongs • Protected - Only to the class and its derived objects • Package - To all objects contained within the same package • Public - To all objects
Language event	When classes represent elements of interfaces, this box allows you to show an operation as triggered by a significant occurrence of an event
Static	The operation is associated with the class, as a consequence, static operations are shared by all instances of the class and have always the same value among instances
Array	Flag defining the return type of the operation. It is true if the value returned is a table
Abstract	The operation cannot be instantiated and thus has no direct instances
Final	The operation cannot be redefined
Read-only	Operation whose execution does not change the class instance
Web service method	If displayed and selected, implies that the operation is used as a web service method

Property	Description
Influent object	Operation that influences the current operation. The most common influence links are "overrides" or "implements" as explained below
Overrides	Indicates which parent operation the current operation is overriding through a generalization link
Implements	Name of the interface operation the current operation is implementing through a realization link
Generic	Specifies that the operation is a generic method. For more information on generic methods, see <i>Generic types and methods</i> on page 40.

The following tabs list objects associated with the operation:

- **Related Diagrams** - lists the model diagrams that are related to the operation. You can add diagrams in this page. For more information, see "Defining related diagrams" in the *Diagrams and Symbols* chapter of the *Core Features Guide*.

Operation Property Sheet Implementation Tab

The Implementation tab allows you to modify the code of an operation. This tab contains the following properties accessible through the sub-tabs at the bottom of the dialog box:

Items	Description
Body	Code of the implementation
Exceptions	Signal raised in response to behavioral faults during system execution
Pre-condition	A constraint that must be true when an operation is invoked
Post-condition	A constraint that must be true at the completion of an operation
Specification	Similar to the pseudo code, it is a description of the normal sequence of actions

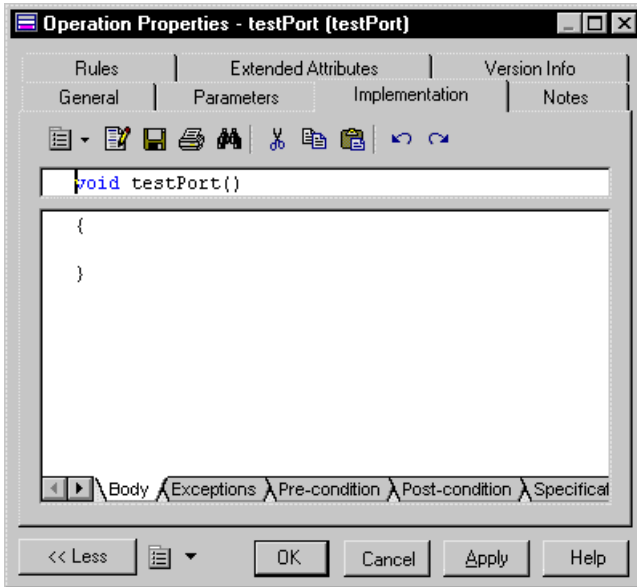

You can use the following tool from the Exceptions tab in the Implementation tab toolbar:

Tool	Description
	Add Exception tool. Opens a selection window that allows you to select an exception classifier to be added. The exception classifier is added where the cursor is positioned

Modifying the Code of an Implementation Operation

To modify the code of an implementation operation:

1. Double-click an implementation operation in the Operations tab of a class that implements an interface to display the operation property sheet .
2. Click the Implementation tab to display the Implementation tab.

3. Click a sub-tab at the bottom of the edit window and type or modify code.
4. Click OK in each of the dialog boxes.

Operation Property Sheet Parameters Tab

The Parameters tab lists the parameters of your operation. A parameter is a specification of a variable that can be changed, passed, or returned. It has a type that indicates the flow of information, a name, and a code.

A parameter has the following properties:

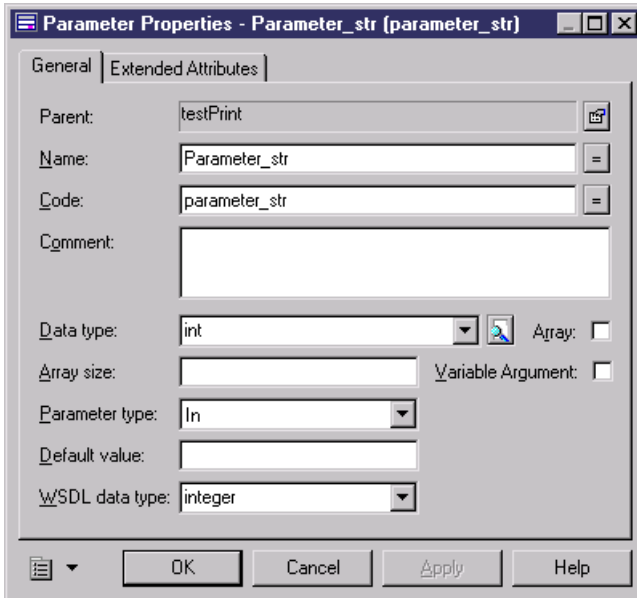

Property	Description
Parent	To which the operation belongs
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Data type	Set of instances sharing the same operations, abstract attributes, relationships, and semantics
Array	When selected, turns attributes into table format
Array size	Specifies an accurate array size when the attribute multiplicity is greater than 1.

Property	Description
Variable Argument	Specifies that the method can take a variable number of parameters for a given argument. You can only select this property if the parameter is the last in the list.
Parameter Type	<p>Direction of information flow for the parameter. Indicates what is returned when the parameter is called by the operation during the execution process. You can choose from the following:</p> <ul style="list-style-type: none"> • In - Input parameter passed by value. The final value may not be modified and information is not available to the caller • In/Out - Input parameter that may be modified. The final value may be modified to communicate information to the caller • Out - Output parameter. The final value may be modified to communicate information to the caller
Default value	<p>Default value when a parameter is omitted. For example:</p> <p>Use an operation <code>oper(string param1, integer param2)</code>, and specify two arguments <code>oper(val1, val2)</code> during invocation. Some languages, like C++, allow you to define a default value that is then memorized when the parameter is omitted during invocation.</p> <p>If the declaration of the method is <code>oper(string param1, integer param2 = default)</code>, then the invocation <code>oper(val1)</code> is similar to <code>oper(val1, default)</code>.</p>
WSDL data type	Only available with Web services. Defines the XML-Schema/SOAP type used during invocation of a Web method (using http or Soap)

Creating an Operation Parameter

To create an operation parameter:

1. Select the Parameters tab in the operation property sheet.
2. Click the Add a Row tool, and then double-click the arrow at the beginning of the new parameter row to open its property sheet.

3. Enter any necessary properties (including the required "Parameter Type" property).
4. Click OK to add the parameter to the operation.

Operation Property Sheet Generic Tab

The Generic tab allows you to specify that the operation is a generic method, and to list its type parameters.

For more information, see *Generic types and methods* on page 40.

Associations (OOM)

An *association* represents a structural relationship between classes or between a class and an interface.

An association can be created in the following diagrams:

- Class Diagram
- Composite Structure Diagram

It is drawn as a solid line between the pair of objects.

In addition to naming the association itself, you can specify a role name for each end in order to describe the function of a class as viewed by the opposite class. For example, a person

considers the company where he works as an employer, and the company considers this person as an employee.

Reflexive Association

A reflexive association is an association between a class and itself.

In the following example, the association Supervise expresses the fact that an employee can, at the same time, be a manager and someone to manage.

In the Dependencies tab of the class, you can see two identical occurrences of the association, this is to indicate that the association is reflexive and serves as origin and destination for the link.

Aggregation

An *aggregation* is a special type of association in which one class represents a larger thing (a whole) made of smaller things (the parts). This is sometimes known as a "has-a" link, and allows you to represent the fact that an object of the whole has objects of the part. In the following example, the family is the whole that can contain children.

You can create an aggregation directly using the Aggregation tool in the Palette. The aggregation symbol in a diagram is the following:

Composition

A *composition* is a special type of aggregation in which the parts are strongly tied to the whole. In a composition, an object may be a part of only one composite at a time, and the composite object manages the creation and destruction of its parts. In the following example, the frame is a part of a window. If you destroy the window object, the frame part also disappears.

You can create a composition directly using the Composition tool in the Palette. The composition symbol in a diagram is the following:

You can define one of the roles of an association as being either an aggregation or a composition. The Container property needs to be defined to specify which of the two roles is an aggregation or a composition.

Creating an Association

You can create an association in any of the following ways:

- Use the Association, Aggregation, or Composition tool in the diagram Palette
- Select **Model > Associations** to access the List of Associations, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Association**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Associations Properties

You can modify an object's properties from its property sheet. To open an association property sheet, double-click its diagram symbol or its Browser entry in the Associations folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for associations.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition. <<implicit>> means that the relationship is not manifest, it is only conceptual
Class A	Name of the class at one end of the association. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object

Property	Description
Class B	Name of the class at the other end of the association. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object
Type	Specifies the type of association. You can choose between: <ul style="list-style-type: none"> • Association • Aggregation – a part-whole relationship between a class and an aggregate class • Composition – a form of aggregation but with strong ownership and co-incident lifetime of parts by the whole
Container	If the association is an aggregation or a composition, the container radio buttons let you define which class contains the other in the association
Association Class	Class related to the current association that completes the association definition

Associations Property Sheet Detail Tab

Each end of an association is called a *role*. You can define its multiplicity, persistence, ordering and changeability. You can also define its implementation.

Property	Description
Role name	Name of the function of the class as viewed by the opposite class
Visibility	Specifies the visibility of the association role, how it is seen outside its enclosing namespace. When the role of an association is visible to another object, it may influence the structure or behavior of the object, or similarly, the other object can affect the properties of the association. You can choose between: <ul style="list-style-type: none"> • Private – only to the object itself • Protected – only to the object and its inherited objects • Package – to all objects contained within the same package • Public – to all objects (option by default)

Property	Description
Multiplicity	<p>The allowable cardinalities of a role are called multiplicity. Multiplicity indicates the maximum and minimum cardinality that a role can have. You can choose between:</p> <ul style="list-style-type: none"> • 0..1 – zero or one • 0..* – zero to unlimited • 1..1 – exactly one • 1..* – one to unlimited • * – none to unlimited <p>An extended attribute exists for each role of an association. It allows you to choose how the association should be implemented. They are available in your current object language, from the Profile\Association\ExtendedAttributes category, under the 'roleAContainer' and 'roleBContainer' names. Such extended attributes are pertinent only for a 'many' multiplicity (represented by *), they provide a definition for collections of associations.</p> <p>For more information on the object language, see the Resource Files and the Public Metamodel chapter in the <i>Customizing and Extending PowerDesigner</i> manual.</p>
Array size	Specifies an accurate array size when the multiplicity is greater than 1.
Changeability	<p>Specifies if the set of links related to an object can be modified once the object has been initialized. You can choose between:</p> <ul style="list-style-type: none"> • Changeable – Associations may be added, removed, and changed freely • Read-only – You are not allowed to modify the association • Frozen – Constant association <p>Add-only – New associations may be added from a class on the opposite end of the association</p>
Ordering	<p>The association is included in the ordering which sorts the list of associations by their order of creation. You can choose between:</p> <ul style="list-style-type: none"> • Sorted – The set of objects at the end of an association is arranged according to the way they are defined in the model • Ordered – The set of objects at the end of an association is arranged in a specific order <p>Unordered – The end of an association is neither sorted nor ordered</p>
Initial value	Lets you type an instruction for initializing migrated attributes, for example 'new client ()'
Navigable	Indicates whether or not information can be transmitted between the two objects linked by the relationship

Property	Description
Persistent	When selected, specifies that the instance of the association is preserved after the process that created this instance terminates
Volatile	Indicates that the corresponding migrated attributes is not a member of the class. It is only defined by the getter and setter operations
Container type	Lets you select a container collection for migrated attributes of complex types
Implementation class	Lets you select the container implementation
Migrated attribute	Name of the migrated association role

For more information on association container and implementation, see *Association implementation* on page 91.

Association Implementation

Associations describe structural relationships between classes that become links between the instances of these classes. These links represent inter-object navigation that is to say the fact that one instance can retrieve another instance through the navigable link.

When an association end is navigable, it means you want to be able to retrieve the instance of the class it is linked to, this instance is displayed as a *migrated attribute* in the current instance of a class. The rolename of this end can be used to clarify the structure used to represent the link.

For example, let us consider an association between class *Company* and class *Person*. Navigation is possible in both directions to allow *Company* to retrieve a list of employees, and each employee to retrieve his company.

PowerDesigner supports different ways for implementing associations in each object language.

Default Implementation

By default, migrated attributes use the class they come from as type.

When the association multiplicity is greater than one, the type is usually an array of the class, displayed with [] signs. In our example, attribute *employee* in class *Company* is of type *Person* and has an array of values. When you instantiate class *Company*, you will have a list of employees to store for each company.

```
public class Company
{
    public String Name;
    public String Catalog;
    public String Address;

    public Person[] employee;
```

Depending on the language you are working with, you may have other ways to implement migrated attributes. PowerDesigner lets you choose an implementation in the Detail tab of the association property sheet.

Container Type and Implementation Class

A *container* is a collection type of objects that stores elements. The container structure is more complex than the array type and provides more methods for accessing elements (test element existence, insert element in collection, and so on) and managing memory allocation dynamically.

You can select a container type from the *Container Type* list. This type will be used by migrated attributes. The code of a migrated attribute that uses a container type contains getter and setter functions used to define the implementation of the association. These functions are visible in the Code Preview tab, but do not appear in the list of operations.

When you use the role migration feature to visualize migrated attributes and select a container type, the generated code is identical.

Depending on the language and the libraries you are using, the container type may be associated with an *implementation class*. In this case, the container type is used as an interface for declaring the collection features, and the implementation class develops this collection. For example, if you select the container type `java.util.Set`, you should know that this collection contains no duplicate elements. You can then select an implementation class among the following: `HashSet`, `LinkedHashSet`, or `TreeSet`.

For more information on container types and implementation classes, see the corresponding language documentation.

More on Implementation Class

The default implementation mechanism is defined in the object language resource file under the Profile\Association category. This mechanism uses templates to define the migrated attribute generated syntax, the operations to generate, and other association details. For example, template *roleAMigratedAttribute* allows you to recover the visibility and initial value of the association role. You can use the resource editor interface to modify implementation details.

For more information template definition, see the Customizing Generation with GTL chapter of the *Customizing and Extending PowerDesigner* manual.

Understanding the Generated Code

When you define an implementation class, association implementation details are always generated in the origin and/or destination classes of the navigable association.

Generation uses specific documentation comment tags to store association information. These documentation comment tags gather all the required details to be able to recreate the association upon reverse engineering. The documentation comment tags are processed during reverse engineering in order to make round-trip engineering possible.

The following documentation tags are used:

- *pdRoleInfo* is used to retrieve the classifier name, container type, implementation class, multiplicity and type of the association
- *pdGenerated* is used to flag automatically generated functions linked to association implementation. These functions should not be reverse engineered otherwise generated and reverse engineered models will be different

Warning! Make sure you do not modify these tags in order to preserve round-trip engineering.

In Java

The javadoc tag syntax is used `/**@tag value*/`.

In the following example, the tag `@pdRoleInfo` is used to store association implementation details, and `@pdGenerated` is used to indicate that the getter method is automatically generated and should not be reverse engineered.

```
/**@pdRoleInfo name=Person coll=java.util.Collection
impl=java.util.LinkedList mult=1..* */
public java.util.Collection employee;
/** @pdGenerated default getter */
public java.util.Collection getEmployee()
{
    if (employee == null)
        employee = new java.util.HashSet();
    return employee;
}
...
```

In C#

The documentation tag `///<tag value />` is used.

In the following example, the tag `<pdRoleInfo>` is used to store association implementation details, and `<pdGenerated>` is used to indicate that the getter method is automatically generated and should not be reverse engineered.

```
///<pdRoleInfo name='Person' coll='System.Collections.ArrayList'
impl='java.util.LinkedList' mult='1..*' type='composition' />
public java.util.Collection employee;
```

```
///<pdGenerated> default getter </pdGenerated>
...
```

In VB .NET

The documentation tag "`<tag value />`" is used.

In the following example, the tag `<pdRoleInfo>` is used to store association implementation details, and `<pdGenerated>` is used to indicate that the getter method is automatically generated and should not be reverse engineered.

```
"<pdRoleInfo name='Person' coll='System.Collections.ArrayList'
impl='java.util.LinkedList' mult='1..*' type='composition' />
public java.util.Collection employee;
"<pdGenerated> default getter </pdGenerated>
...
```

Creating an Association Class

You can add properties to an association between classes or interfaces by creating an *association class*. It is used to further define the properties of an association by adding attributes and operations to the association.

An association class is an association that has class properties, or a class that has association properties. In the diagram, the symbol of an association class is a connection between an association and a class. Association classes must be in the same package as the parent association; you cannot use the shortcut of a class to create an association class.

The class used to create an association class cannot be reused for another association class. However, you can create other types of links to and from this class.

In the following example, the classes Student and Subject are related by an association exam. However, this association does not specify the date of the exam. You can create an association class called Exam that will indicate additional information concerning the association.

1. Right-click the association and select Add Association Class from the contextual menu.
2. Double-click the association to open its property sheet, and click the Create button to the right of the Association class listbox.

A dashed link is automatically added between the class and the association.

Migrating Association Roles in a Class Diagram

You can migrate association roles and create attributes before generation. This is very convenient for many reasons including data type customization and the ability to change the attribute order in the list of attributes. The last feature is especially important in XML.

Regardless of the navigability, the migration creates an attribute and sets its properties as follows:

- Name and code of the attribute: association role if already set, if not the association name
- Data type: code of the classifier linked by the association
- Multiplicity: role multiplicity
- Visibility: role visibility

Migration Rules

The following rules apply when migrating association roles:

- If the migrated attribute name is the same as the role name, then modifying the role name synchronizes the migrated attribute name
- If the migrated attribute data type is the same as the role classifier, then modifying the role multiplicity synchronizes the migrated attribute multiplicity
- If the code of the classifier, linked by the association, changes, then the migrated attribute data type is automatically synchronized
- If you manually change the migrated attribute, the synchronization does not work, the association role is not synchronized
- The migrated attribute is automatically deleted if the association is deleted

After migration, the property sheet of the new attribute displays the name of the association in the Migrated from box in the Detail tab.

Migrating Navigable Roles

You can migrate the navigable role of an association and turn it into an attribute:

1. Right-click the association in the diagram.

2. Select **Migrate > Migrate Navigable Roles** from the association contextual menu.

An attribute is created and named after the navigable role of the association followed by the code of the classifier.

Rebuilding Data Type Links

If a classifier data type is not linked to its original classifier, you can use the Rebuild Data Type Links feature to restore the link. This feature looks for all classifiers of the current model and links them, if needed, to the original classifier.

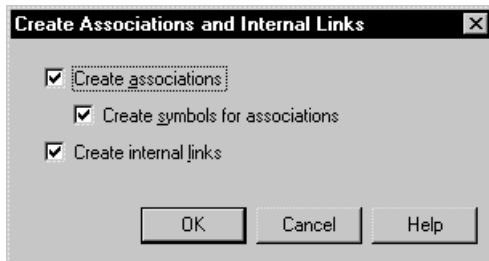

The Rebuild Data Type Links scans the following data types:

- Attribute data type: an association is created and the attribute is flagged as Migrated Attribute
- Parameter data type: an association is created and links the original classifier
- Operation return type: an association is created and links the original classifier

In some cases, for C++ in particular, this feature is very useful to keep the synchronization of the link even if the data type changes, so that it keeps referencing the original class.

The Rebuild Data Type Links contains the following options:

1. Select **Tools > Rebuild Data Type Links** to open the Create Associations and Internal Links window.

2. Set the following options as needed:

Option	Description
Create associations	Looks for attributes whose data type matches a classifier and links the attributes to the newly created association as migrated attributes
Create symbols for associations	Creates a symbol of the new association
Create internal links	Creates a link between the return type or parameter data type and the classifier it references

3. Click OK.

Linking an Association to an Instance Link

You can drag an association node from the Browser and drop it into the communication or object diagrams. This automatically creates two objects, and an instance link between them.

Both objects are instances of the classes or interfaces, and the instance link is an instance of the association.

Generalizations (OOM)

A *generalization* is a relationship between a general element (the parent) and a more specific element (the child). The more specific element is fully consistent with the general element and contains additional information.

A generalization can be created in the following diagrams:

- Class Diagram
- Composite Structure Diagram
- Component Diagram
- Use Case Diagram

You create a generalization relationship when several objects have common behaviors. You can also create a generalization between a shortcut of an object and an object but, if the link is oriented, only the parent object can be the shortcut.

Generalizations in a Use Case Diagram

In a use case diagram, you can create a generalization between:

- Two actors
- Two use cases

For example two or more actors may have similarities, and communicate with the same set of use cases in the same way. This similarity is expressed with generalization to another actor. In this case, the child actors inherit the roles, and relationships to use cases held by the parent actor. A child actor includes the attributes and operations of its parent.

Generalizations in a Class or Composite Structure Diagram

In a class diagram, you can create a generalization between:

- Two classes
- Two interfaces

For example, an animal is a more general concept than a cat, a dog or a bird. Inversely, a cat is a more specific concept than an animal.

Animal is a super class. Cat, Dog and Bird are sub-classes of the super class.

Generalizations in a Component Diagram

In a component diagram, you can create a generalization between two components, as shown below:

Creating a Generalization

You can create a generalization in any of the following ways:

- Use the Generalization tool in the diagram Palette
- Select **Model > Generalizations** to access the List of Generalizations, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Generalization**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Generalization Properties

You can modify an object's properties from its property sheet. To open a generalization property sheet, double-click its diagram symbol or its Browser entry in the Generalizations folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Parent	Specifies the parent object. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Child	Specifies the child object. Click the Properties tool to the right of this box to access the property sheet of the specified object.
Stereotype	Extends the semantics of the object beyond the core UML definition. The stereotype <<implementation>> means that the child object inherits the implementation of the parent object but does not make its interfaces public, nor support them (thus violating its substitutability).
Visibility	Specifies the visibility of the object, how it is seen outside its enclosing namespace. You can choose between: <ul style="list-style-type: none"> • Private – only to the generalization itself • Protected – only to the generalization and its inherited objects • Package – to all objects contained within the same package • Public – to all objects (option by default)
Generate parent class as table	Selects the "Generate table" persistence option in the Detail tab of the parent class property sheet. If this option is not selected, the "Migrate columns" persistence option of the parent class is selected.
Generate child class as table	Selects the "Generate table" persistence option in the Detail tab of the child class property sheet. If this option is not selected, the "Migrate columns" persistence option of the child class is selected.
Discriminant Attribute	Specifies a persistent attribute (with a stereotype of <<specifying>>) in the parent table. Click the New tool to create a new attribute. This attribute will only be generated if the child table is not.

If the generalization is created in a use case diagram, you cannot change the type of objects linked by the generalization. For example, you cannot attach the dependency coming from a use case to a class, or an interface.

Dependencies (OOM)

A *dependency* is a semantic relationship between two objects, in which a change to one object (the influent object) may affect the semantics of the other object (the dependent object).

A dependency can be created in the following diagrams:

- Class Diagram
- Composite Structure Diagram
- Object Diagram
- Use Case Diagram
- Component Diagram
- Deployment Diagram

The dependency relationship indicates that one object in a diagram uses the services or facilities of another object. You can also define dependencies between a package and a modeling element.

Dependencies in a Class or Composite Structure Diagram

In a class diagram, you can create a dependency between:

- A class and an interface (and vice versa)
- Two classes
- Two interfaces

For example:

Dependencies in an Object Diagram

In an object diagram, you can create a dependency between two objects as follows:

Dependencies in a Use Case Diagram

In a use case diagram, you can create a dependency between:

- An actor and a use case (and vice versa)
- Two actors
- Two use cases

Buying a computer from a web site involves the activity of finding the product page within the seller's web site:

Dependencies in a Component Diagram

In a component diagram, you can create a dependency between two components as shown below. You cannot create a dependency between a component and an interface.

When using a dependency, you can nest two components by using a stereotype.

Dependencies in a Deployment Diagram

In a deployment diagram, a dependency can be created between nodes, and component instances as follows:

Creating a Dependency

You can create a dependency in any of the following ways:

- Use the Dependency tool in the diagram Palette
- Select **Model > Dependencies** to access the List of Dependencies, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Dependency**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Dependency Properties

You can modify an object's properties from its property sheet. To open a dependency property sheet, double-click its diagram symbol or its Browser entry in the Dependencies folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Influent	Selected use case or actor influences the dependent object. Changes on the influent object affect the dependent object. You can click the Properties tool beside this box to display the object property sheet
Dependent	Selected use case or actor depends on the influent object. Changes on the dependent object do not affect the influent object. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.

Property	Description
Stereotype	<p>Extends the semantics of the object beyond the core UML definition. The following common stereotypes are provided by default:</p> <ul style="list-style-type: none"> • << Access >> - Public contents of the target package that can be accessed by the source package • << Bind >> - Source object that instantiates the target template using the given actual parameters • << Call >> - Source operation that invokes the target operation • << Derive >> - Source object that can be computed from the target • << Extend >> - (Use Case/Class) Target object extends the behavior of the source object at the given extension point • << Friend >> - Source object that has special visibility towards the target • << Import >> - Everything declared public in the target object becomes visible to the source object, as if it were part of the source object definition • << Include >> - (Use Case/Class) Inclusion of the behavior of the first object into the behavior of the client object, under the control of the client object • << Instantiate >> - Operations on the source class create instances of the target class • << Refine >> - The target object has a greater level of detail than the source object • << Trace >> - Historical link between the source object and the target object • << Use >> - Semantics of the source object are dependent on the semantics of the public part of the target object • << ejb-ref >> - (Java only) Used in Java Generation to create references to EJBs (entity beans and session beans) for generating the deployment descriptor • << sameFile >> - (Java only) Used in Java Generation to generate Java classes of visibility protected or private within a file corresponding to a class of visibility public

If the dependency is created in a use case diagram, you cannot change the objects linked by the dependency. For example, you cannot attach the dependency coming from a use case to a class or an interface.

Realizations (OOM)

A realization is a relationship between a class or component and an interface.

A realization can be created in the following diagrams:

- Class Diagram

- Composite Structure Diagram
- Component Diagram

In a realization, the class implements the methods specified in the interface. The interface is called the specification element and the class is called the implementation element. You can also create a realization between a shortcut of an interface and a class. Whenever the link is oriented, only the parent object can be the shortcut.

The arrowhead at one end of the realization always points towards the interface.

Creating a Realization

You can create a realization in any of the following ways:

- Use the Realization tool in the diagram Palette
- Select **Model > Realizations** to access the List of Realizations, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Realizations**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Realization Properties

You can modify an object's properties from its property sheet. To open a realization property sheet, double-click its diagram symbol or its Browser entry in the Realizations folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Interface	Name of the interface that carries out the realization. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Class	Name of the class for which the realization is carried out

Property	Description
Stereotype	Extends the semantics of the object beyond the core UML definition.

Require Links (OOM)

Require links connect classifiers and interfaces. A *require link* can connect a class, a component, or a port on the outside of one of these classifiers to an interface.

A require link can be created in the following diagrams:

- Class Diagram
- Composite Structure Diagram
- Component Diagram

Require Links in a Class Diagram

In the example below, require links connect the class `TitleImpl` with the interfaces `java.math.stat` and `java.sql.connection`. Note how the require link can proceed from a port or directly from the class

Creating a Require Link

You can create a require link in any of the following ways:

- Use the Require Link/Connector tool in the diagram Palette
- Right-click the model or package in the Browser, and select **New > Require Link**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Require Link Properties

You can modify an object's properties from its property sheet. To open a require link property sheet, double-click its diagram symbol or Browser entry.

The General tab contains the following properties:

Property	Description
Name	The name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.

Property	Description
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Interface	Specifies the interface to be linked to. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Client	Specifies the class, port, or component to be linked to.
Stereotype	Extends the semantics of the object beyond the core UML definition.

Assembly Connectors (OOM)

Assembly connectors represent the paths of communication by which parts in your classifiers request and provide services to each other.

An assembly connector can be created in the following diagrams:

- Composite Structure Diagram
- Component Diagram

Assembly Connectors in a Composite Structure Diagram

In the example below an assembly connector connects the supplier part "TitleDataAccess" to the client part "TitleManager".

Assembly Connectors in a Component Diagram

In the example below an assembly connector connects the supplier part "TitleDataAccess" to the client part "TitleManager".

Creating an Assembly Connector

You can create an assembly connector in the following way:

- Use the Require Link/Connector tool in the diagram Palette

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Assembly Connector Properties

You can modify an object's properties from its property sheet. To open an assembly connector property sheet, double-click its diagram symbol or Browser entry.

The General tab contains the following properties:

Property	Description
Name	The name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Client	Specifies the part requesting the service. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Supplier	Specifies the part providing the service. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Interface	Specifies the interface that the supplier part uses to provide the service. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.

Delegation Connectors (OOM)

Delegation connectors represent the paths of communication by which parts inside a classifier connect to ports on the outside of that classifier and request and provide services to each other.

A delegation connector can be created in the following diagrams:

- Composite Structure Diagram
- Component Diagram

Delegation Connectors in a Composite Structure Diagram

In the example below a delegation connector connects the supplier port "sql" on the outside of the class "TitleImp" to the client part "TitleDataAccess" via a port "sql". A second delegation connector connects the supplier part "TitleManager" via the port "mgr" to the port "mgr" on the outside of the class "TitleImp".

Delegation Connectors in a Component Diagram

In the example below a delegation connector connects the supplier part "TitleDataAccess" via the port "sql" to the client port "sql" on the outside of the component "PersistentTitle".

Creating a Delegation Connector

You can create a delegation connector in the following way:

- Use the Require Link/Connector tool in the diagram Palette

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Delegation Connector Properties

You can modify an object's properties from its property sheet. To open a delegation connector property sheet, double-click its diagram symbol or Browser entry.

The General tab contains the following properties:

Property	Description
Name	The name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Client	Specifies the part or port requesting the service. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Supplier	Specifies the part or port providing the service. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Stereotype	Extends the semantics of the object beyond the core UML definition.

Annotations (OOM)

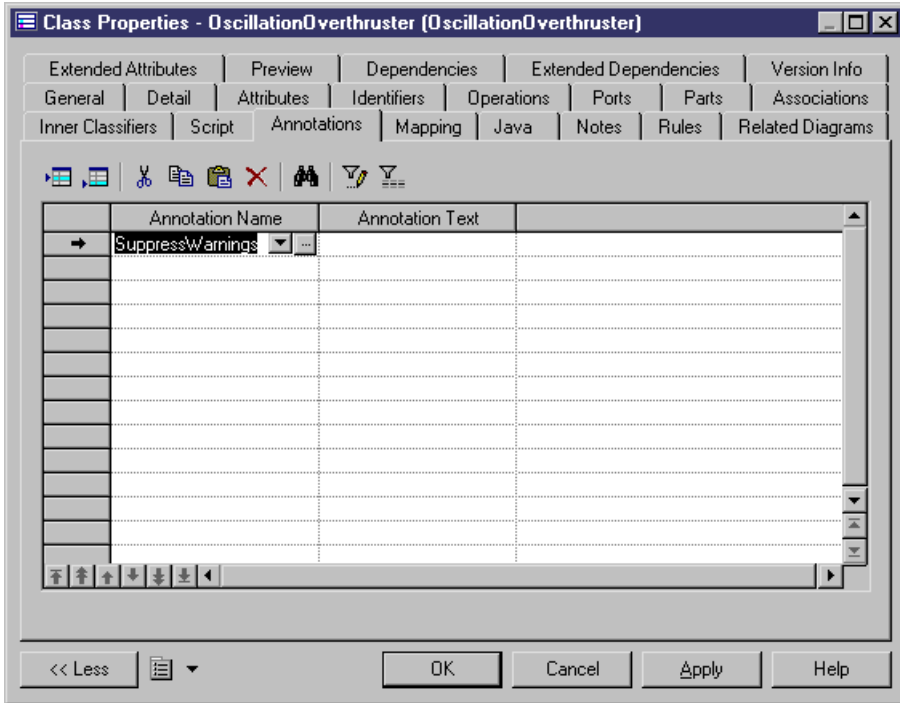

Java 5.0 and the .NET languages (C# 2.0 and VB 2005) provide methods for adding metadata to code. PowerDesigner provides full support for Java annotations and .NET custom attributes. For language-specific information, see the relevant chapter in Part Two of this book.

This metadata can be accessed by post-processing tools or at run-time to vary to behavior of the system.

Attaching an Annotation to a Model Object

PowerDesigner supports the Java 5.0 built-in annotations, the .NET 2.0 built-in custom attributes and for both Java 5.0 and .NET 2.0, also allows you to create your own. You can attach annotations to types and other model objects:

1. Double-click a class or other object to open its property sheet, and then click the Annotations tab.
2. Click in the Annotation Name column, and select an annotation from the list.

3. If the annotation takes parameters, you can enter them directly in the Annotation Text column or click the ellipsis button to open the Annotation Editor.
4. [optional] Click the Preview tab to see the code that will be generated for the class, with its declaration preceded by the annotation:

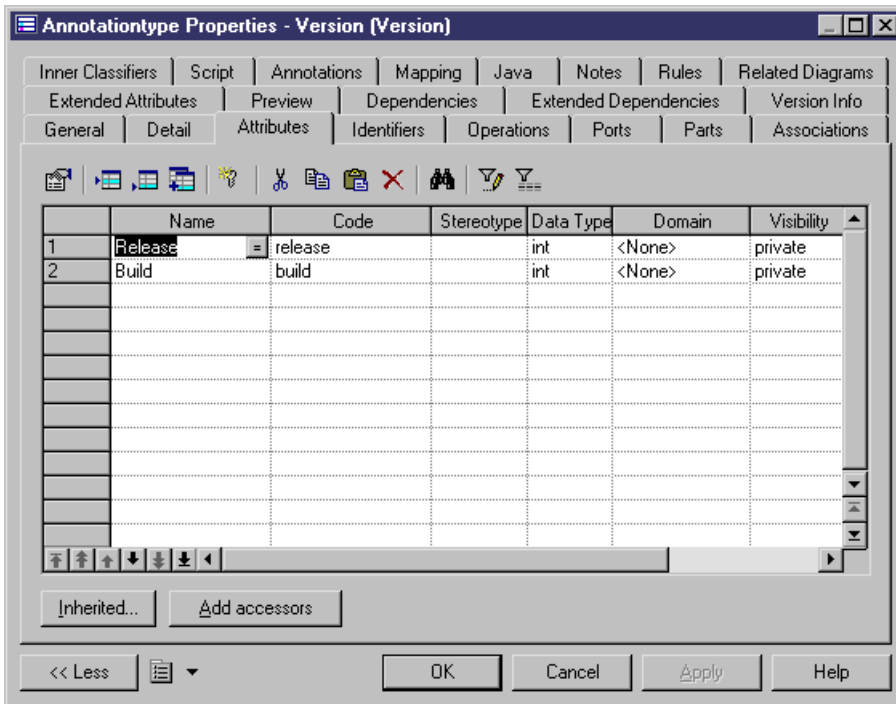

5. Click OK to return to the diagram.

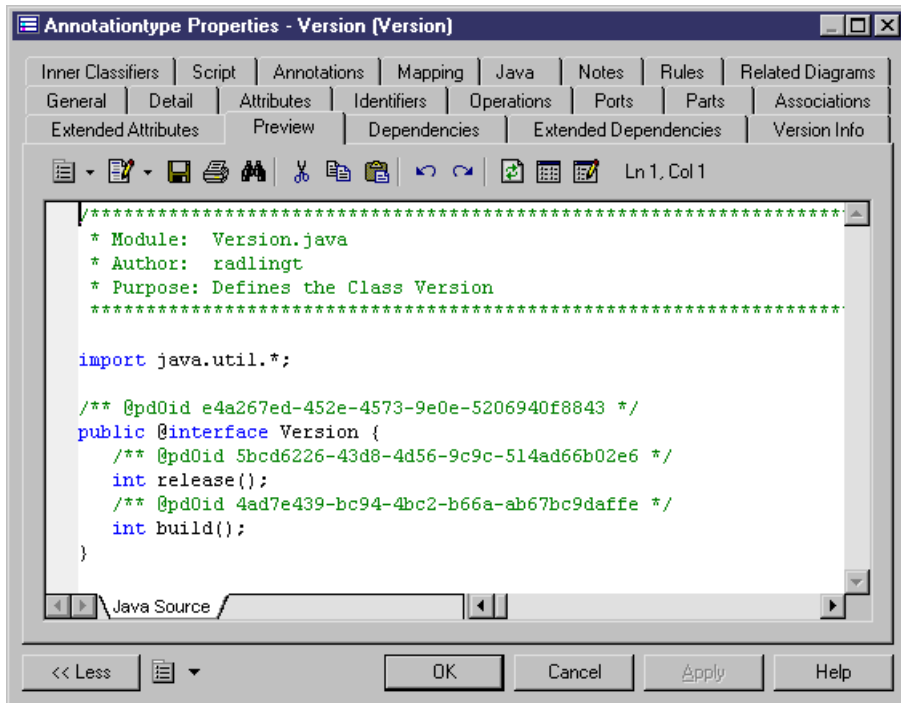

Creating a New Annotation Type

You can create new annotation types to attach to your objects.

1. Create a class and then double-click it to access its property sheet.
2. On the General tab, in the Stereotype list:
 - For Java 5.0 - select AnnotationType
 - For .NET 2.0 - select AttributeType
3. Click the Attributes tab, and add an attribute for each parameter accepted by the annotation type.

4. [optional] Click the Preview tab to review the code to be generated for the annotation type:

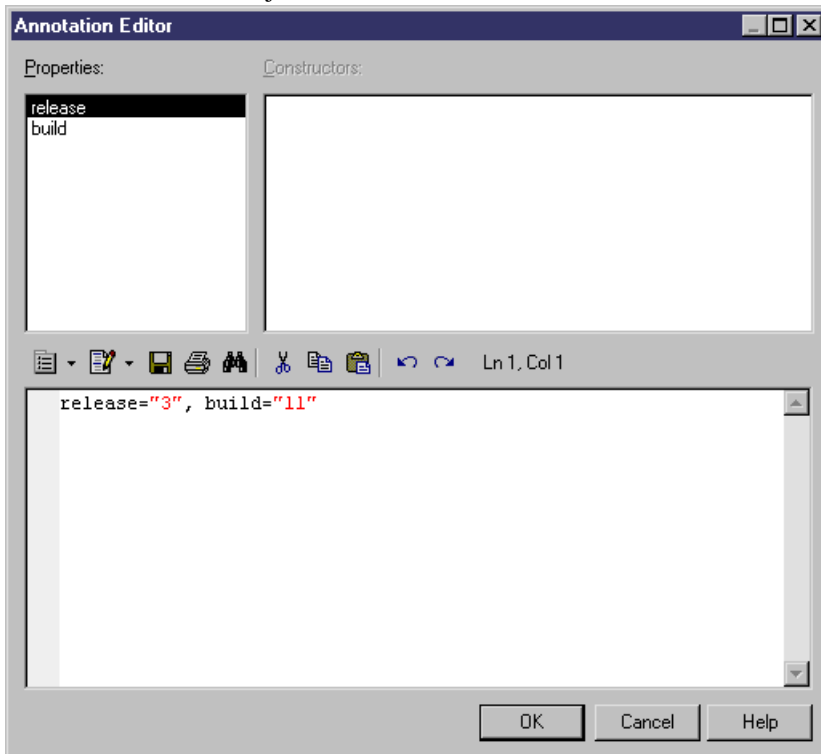

5. Click OK to return to the diagram. The annotation type will be represented as follows:

Using the Annotation Editor

The Annotation Editor assists you in specifying the values for annotation parameters. It is accessible by clicking the ellipsis button in the Annotation Text Column on the Annotations tab of a class or other object:

The top panes provide lists of available properties and constructors, which you can double-click to add them to the bottom, editing pane.

Instance Links (OOM)

An *instance link* represents a connection between two objects. It is drawn as a solid line between two objects.

An instance link can be created in the following diagrams:

- Communication Diagram
- Object Diagram

Instance Links in an Object Diagram

Instance links have a strong relationship with associations of the class diagram: associations between classes, or associations between a class and an interface can become instance links (instances of associations) between objects in the object diagram. Moreover, the instance link symbol in the object diagram is similar to the association symbol in the class diagram, except that the instance link symbol has no cardinalities.

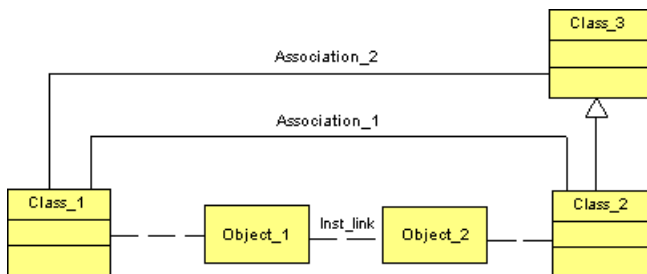

The roles of the instance link are duplicated from the roles of the association. An instance link can therefore be an aggregation or a composition, exactly like an association of the class diagram. If it is the case, the composition or aggregation symbol is displayed on the instance link symbol. The roles of the association are also displayed on the instance link symbol provided you select the Association Role Names display preference in the Instance Link category.

Example

The following figure shows Object_1 as instance of Class_1, and Object_2 as instance of Class_2. They are linked by an instance link. It shows Class_1 and Class_2 linked by an association. Moreover, since Class_2 is associated with Class_1 and also inherits from Class_3, there is an association between Class_1 and Class_3.

The instance link between Object_1 and Object_2 in the figure can represent Association_1 or Association_2.

You can also use shortcuts of associations, however you can only use it if the model to which the shortcut refers is open in the workspace.

Instance Links Behavior

The following rules apply to instance links:

- When an association between classes becomes an instance link, both classes linked by the association, and both classes of the objects linked by the instance link must match (or the class of the object must inherit from the parent classes linked by the association). This is also valid for an association between a class and an interface
- Two instance links can be defined between the same source and destination objects (*parallel instance links*). If you merge two models, the Merge Model feature differentiates parallel instance links according to their class diagram associations
- You can use reflexive instance links (same source and destination object)

Instance Links in a Communication Diagram

An instance link represents a connection between objects, it highlights the communication between objects, hence the name 'communication diagram'. It is drawn as a solid line between:

- Two objects
- An object and an actor (and vice versa)

An instance link can be an instance of an association between classes, or an association between a class and an interface.

The role of the instance link comes from the association. The name of an instance link comprises the names of both objects at the extremities, plus the name of the association.

The symbol of the instance link may contain several message symbols attached to it.

Instance links hold an ordered list of messages. The *sequence numbers* specify the order in which messages are exchanged between objects. For more information, see *Messages (OOM)* on page 138.

Instance Links Behavior

The following rules apply to instance links:

- You can use a recursive instance link with an object (same source and destination object)
- Two instance links can be defined between the same source and destination objects (*parallel instance links*)
- When you delete an instance link, its messages are also deleted if no sequence diagram already uses them
- When an association between classes turns into an instance link, both classes linked by the association, and both classes of the objects linked by the instance link must match (or the class of the object must inherit from the parent classes linked by the association). This is also valid for an association between a class and an interface
- If you change one end of an association, the instance link that comes from the association is detached
- When you copy and paste, or move an instance link, its messages are automatically copied at the same time
- When the extremities of the message change, the message is detached from the instance link
- If you use the Show Symbols feature to display an instance link symbol, all the messages attached to the instance link are displayed

Creating an Instance Link

You can create an instance link in any of the following ways:

- Use the Instance Link tool in the diagram Palette
- Select **Model > Instance Links** to access the List of Instance Links, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Instance Link**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Drag and Drop Associations in an Object Diagram

You can drag an association from the Browser and drop it into an object diagram. This creates an instance link and two objects, instances of these classes or interfaces.

Instance Link Properties

You can modify an object's properties from its property sheet. To open an instance link property sheet, double-click its diagram symbol or its Browser entry in the Instance Links folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users. Calculated, read-only value.
Code	Specifies the technical name of the object, which is used for generating code or scripts. Calculated, read-only value.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Object A	Name of the object at one end of the instance link. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Object B	Name of the object at the other end of the instance link. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Association	Association between classes (or association between a class and an interface) that the instance link uses to communicate between objects of these classes. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.

For more information on the different ways to modify the instance link properties, see "Object Properties" in the Objects chapter of the *Core Features Guide*.

Domains (OOM)

Domains define the set of values for which an attribute is valid. They are used to enforce consistent handling of data across the system. Applying domains to attributes makes it easier to standardize data characteristics for attributes in different classes.

A domain can be created in the following diagrams:

- Class Diagram

In an OOM, you can associate the following properties with a domain:

- Data type
- Check parameters
- Business rules

Creating a Domain

You can create a domain in any of the following ways:

- Select **Model > Domains** to access the List of Domains, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Domains**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Domain Properties

You can modify an object's properties from its property sheet. To open a domain property sheet, double-click its Browser entry in the Domains folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for domains.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Data type	Form of the data corresponding to the domain ; numeric, alphanumeric, Boolean, or others
Multiplicity	<p>Specification of the range of allowable number of values attributes using this domain may hold. The multiplicity of a domain is useful when working with a multiple attribute for example. The multiplicity is part of the data type and both multiplicity and data type may come from the domain. You can choose between:</p> <ul style="list-style-type: none"> • 0..1 – zero or one • 0..* – zero to unlimited • 1..1 – exactly one • 1..* – one to unlimited • * – none to unlimited

The tables below indicates the data types for which you can specify:

- Fixed length
- Maximum length
- Decimal precision

Numeric Data Types

Conceptual data type	Content	Length	Mandatory Precision
Integer	32-bit integer	—	—
Short Integer	16-bit integer	—	—
Long Integer	32-bit integer	—	—
Byte	256 values	—	—
Number	Numbers with a fixed decimal point	Fixed	
Decimal	Numbers with a fixed decimal point	Fixed	
Float	32-bit floating point numbers	Fixed	—
Short Float	Less than 32-bit point decimal number	• —	—
Long Float	64-bit floating point numbers	—	—
Money	Numbers with a fixed decimal point	Fixed	
Serial	Automatically incremented numbers	Fixed	—
Boolean	Two opposing values (true/false; yes/no; 1/0)	—	—

Character Data Types

Conceptual data type	Content	Length
Characters	Character strings	Fixed
Variable Characters	Character strings	Maximum
Long Characters	Character strings	Maximum
Long Var Characters	Character strings	Maximum
Text	Character strings	Maximum
Multibyte	Multibyte character strings	Fixed
Variable Multibyte	Multibyte character strings	Maximum

Time Data Types

Conceptual data type	Content
Date	Day, month, year

Conceptual data type	Content
Time	Hour, minute, and second
Date & Time	Date and time
Timestamp	System date and time

Other Data Types

Conceptual data type	Content	Length
Binary	Binary strings	Maximum
Long Binary	Binary strings	Maximum
Bitmap	Images in bitmap format (BMP)	Maximum
Image	Images	Maximum
OLE	OLE links	Maximum
Other	User-defined data type	—
Undefined	Not yet defined data type	—

Domain Property Sheet Detail Tab

The Detail tab contains a Persistent groupbox whose purpose is to improve the generation of code and data types during generation of a CDM or a PDM from an object-oriented model.

The complete list of options on this tab is as follows:

Property	Description
Persistent	Groupbox for valid generation of CDM or PDM persistent models. Defines a model as persistent For more information on object persistence, see <i>Managing Object Persistence During OOM to PDM Generation</i> on page 292.
Data Type	Specifies a persistent data type used in the generation of a persistent model, either a CDM or a PDM. The persistent data type is defined from default PowerDesigner conceptual data types
Length	Maximum number of characters of the persistent data type.
Precision	Number of places after the decimal point, for persistent data type values that can take a decimal point.

Domain Property Sheet Other Tabs

The following tabs are also frequently used when defining domains

Property	Description
Standard checks	Check parameters defined for the domain
Additional checks	Domain constraints or validation rules not defined by standard check parameters
Rules	Business rules attached to the domain

Updating Attributes Using a Domain in an OOM

When you modify a domain, you can choose to automatically update the following properties for attributes using the domain:

- Data type
- Check parameters
- Business rules

1. Select **Model > Domains** to display the list of domains.
2. Click a domain from the list, and then click the Properties tool to display its property sheet.

Note: You also access a domain property sheet by double-clicking the appropriate domain in the Browser.

3. Type or select domain properties as required in the tabbed pages and click OK. If the domain is used by one or more attributes, an update confirmation box asks you if you want to update Data type and Check parameters for the attributes using the domain.
4. Select the properties you want to update for all attributes using the domain and click Yes.

Check Parameters (OOM)

Check parameters are sets of conditions which data must satisfy to remain valid. They are attached to attributes and domains. They are principally used in a CDM or a PDM. They are of importance only when importing a CDM or importing a PDM into an OOM. They are not used in the OOM alone.

There are three types of check parameters you can therefore use in an OOM:

Parameter type	Description
Standard parameters	Common data constraints defining a data range

Parameter type	Description
Additional check parameters	SQL expression defining a data constraint using variables instantiated with standard parameter values
Validation rule	Business rule defined as a server expression

Setting Standard Check Parameters for Objects in an OOM

Standard parameters indicate common data constraints.

Parameter	Description
Minimum	Lowest acceptable numeric value
Maximum	Highest acceptable numeric value
Default	Value assigned in absence of an expressly entered value
Format	Data format (for example, 9999.99)
Unit	Standard measure
Uppercase	Forces all alphabetical characters to uppercase
Lowercase	Forces all alphabetical characters to lowercase
Cannot Modify	Protects from changes, results in a non modifiable attribute
List of Values	Authorized values

1. Click the Standard Checks tab in the property sheet of a domain or an attribute.
2. Select your standard parameters as required, and then click OK.

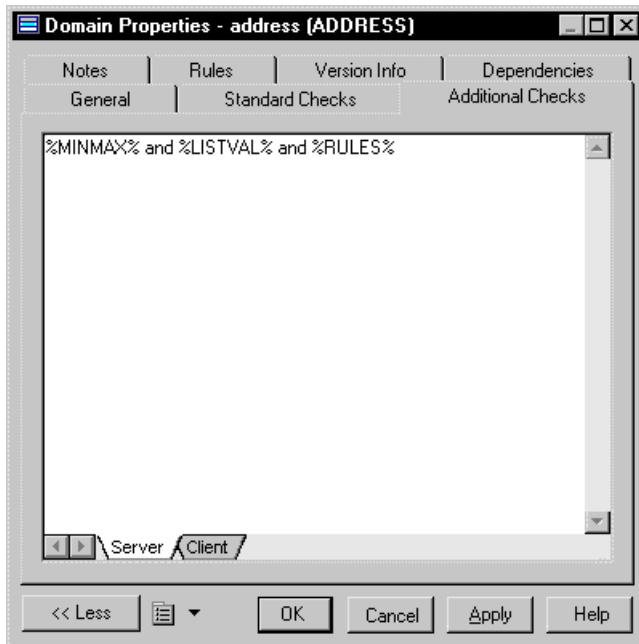

Defining Additional Check Parameters for Objects in an OOM

You can use the following variables as check parameters for domains and attributes:

Variable	Description
%MINMAX%	Minimum and maximum values defined in Values groupbox on Standard Checks tab
%LISTVAL%	Customized values defined in List Values groupbox on Standard Checks tab
%RULES%	Validation rule expression defined on Expression tab of the Rules property sheet

You define additional check parameters for data constraints where standard check parameters are not sufficient.

1. Select **Model > Domains** to open the List of Domains.
2. Click a domain from the list, and then click the Properties tool to display its property sheet.
3. Click the Additional Checks tab, and type your required expressions, using the variables %MINMAX%, %LISTVAL%, and %RULES%.

4. Click OK.

CHAPTER 4 Building Dynamic Diagrams

The diagrams in this chapter allow you to model the dynamic behavior of your system, how its objects interact at run-time. PowerDesigner provides four types of diagrams for modeling your system in this way:

- A *communication diagram* represents a particular use case or system functionality in terms of interactions between objects, while focusing on the object structure. For more information, see *Communication Diagram Basics* on page 125.
- A *sequence diagram* represents a particular use case or system functionality in terms of interactions between objects, while focusing on the chronological order of the messages sent. For more information, see *Sequence Diagram Basics* on page 128.
- A *activity diagram* represents a particular use case or system functionality in terms of the actions or activities performed and the transitions triggered by the completion of these actions. It also allows you to represent conditional branches. For more information, see *Activity Diagram Basics* on page 131.
- A *statechart diagram* represents a particular use case or system functionality in terms of the states that a classifier passes through and the transitions between them. For more information, see *Statechart Diagram Basics* on page 134.
- An *interaction overview diagram* provides a high level view of the interactions that occur in your system. For more information, see *Interaction Overview Diagram Basics* on page 137.

Communication Diagram Basics

A *communication diagram* is a UML diagram that provides a graphical view of the interactions between objects for a use case scenario, the execution of an operation, or an interaction between classes, with an emphasis on the system structure.

You can use one or more communication diagrams to enact a use case or to identify all the possibilities of a complex behavior.

A communication diagram conveys the same kind of information as a sequence diagram, except that it concentrates on the object structure in place of the chronology of messages passing between them.

A communication diagram shows actors, objects (instances of classes) and their communication links (called instance links), as well as messages sent between them. The messages are defined on instance links that correspond to a communication link between two interacting objects. The order in which messages are exchanged is represented by sequence numbers.

Analyzing a Use Case

A communication diagram can be used to refine a use case behavior or description. This approach is useful during requirement analysis because it may help identify classes and associations that did not emerge at the beginning.

You can formalize the association between the use case and the communication diagram by adding the diagram to the Related Diagrams tab of the property sheet of the use case.

It is often necessary to create several diagrams to describe all the possible scenarios of a use case. In this situation, it can be helpful to use the communication diagrams to discover all the pertinent objects before trying to identify the classes that will instantiate them. After having identified the classes, you can then deduce the associations between them from the instance links between the objects.

The major difficulty with this approach consists in identifying the correct objects to transcribe the action steps of the use case. An extension to UML, "Robustness Analysis" can make this process easier. This method recommends separating objects into three types:

- Boundary objects are used by actors when communicating with the system; they can be windows, screens, dialog boxes or menus
- Entity objects represent stored data like a database, database tables, or any kind of transient object such as a search result
- Control objects are used to control boundary and entity objects, and represent the transfer of information

PowerDesigner supports the Robustness Analysis extension through an extended model definition. For more information, see the "Using profiles: a case study" in the Extending your Models with Profiles chapter of the *Customizing and Extending PowerDesigner* manual.

Analyzing a Class Diagram

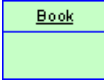

Building a communication diagram can also be the opportunity to test a static model at the conception level; it may represent a scenario in which classes from the class diagram are instantiated to create the objects necessary to run the scenario.

It complements the class diagram that represents the static structure of the system by specifying the behavior of classes, interfaces, and the possible use of their operations.

You can create the necessary objects and instance links automatically by selecting the relevant classes and associations in a class diagram, and then pressing CTRL+SHIFT while dragging and dropping them into an empty communication diagram. Then you have simply to add the necessary messages.

Communication Diagram Objects

PowerDesigner supports all the objects necessary to build communication diagrams.

Object	Tool	Symbol	Description
Actor			An external person, process or something interacting with a system, sub-system or class. See <i>Actors (OOM)</i> on page 13.
Object			Instance of a class. See <i>Objects (OOM)</i> on page 55.
Instance link			Communication link between two objects. See <i>Instance Links (OOM)</i> on page 114.
Message			Interaction that conveys information with the expectation that action will ensue. It creates an instance link by default when no one exists. See <i>Messages (OOM)</i> on page 138.

Creating a Communication Diagram

You can create a communication diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Communication Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Communication Diagram**.

To create a new OOM with a communication diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Communication Diagram** as the first diagram, and click **OK**.

Creating a Communication Diagram from a Sequence Diagram

You can create a communication diagram from a sequence diagram. The new communication diagram reuses the objects and messages from the sequence diagram, and creates instance links between the objects that communicate using messages. The conversion also updates any message sequence numbers, based upon the relative position of messages on the timeline.

Note that when you create a communication diagram from a sequence diagram, the two do not remain synchronized – changes made in one diagram will not be reflected in the other.

Right-click in the background of the sequence diagram and select Create Default Communication Diagram in the contextual menu.

or

Select **Tools > Create Default Communication Diagram**.

Sequence Diagram Basics

A *sequence diagram* is a UML diagram that provides a graphical view of the chronology of the exchange of messages between objects and actors for a use case, the execution of an operation, or an interaction between classes, with an emphasis on their chronology.

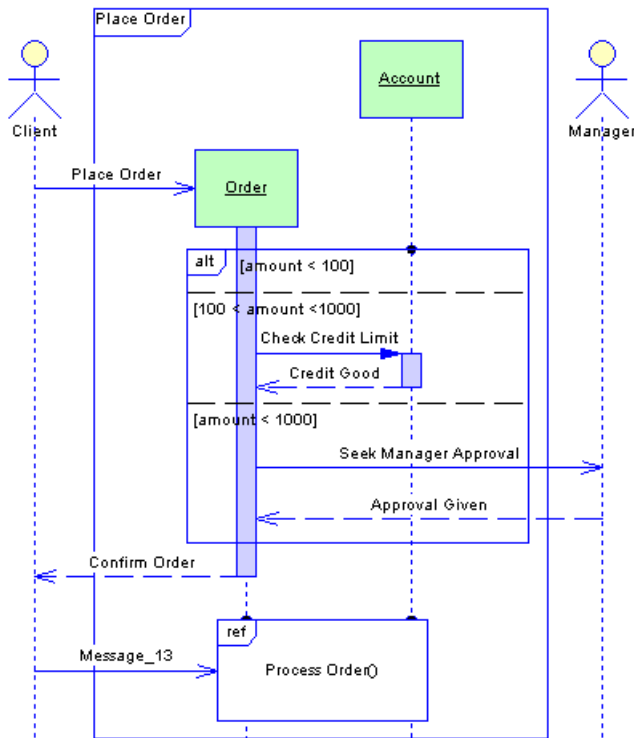

You can use one or more sequence diagrams to enact a use case or to identify all the possibilities of a complex behavior.

A sequence diagrams conveys the same kind of information as a communication diagram, except that it concentrates on the chronology of messages passing between the objects in place of their structure.

A sequence diagram shows actors, objects (instances of classes) and the messages sent between them. By default, PowerDesigner provides an "interaction frame", which surrounds the objects in the diagram. Messages can originate from or be sent to any point on the interaction frame, which acts as the exterior of the system (or part thereof) being modeled, and these *gates* can be used in place of actor objects. For more information about using the interaction frame in this way, see *Messages and gates* on page 147.

One of the major advantages of a sequence diagram over a communication diagram is that you can reference common interactions and easily specify alternative or parallel scenarios using interaction fragments. Thus, you can describe in a single sequence diagram a number of related interactions that would require multiple communication diagrams.

In the following example, the Client actor places an order. The Place Order message creates an Order object. An interaction fragment handles various possibilities for checking the order. The Account object and Manager actor may interact with the order depending on its size. Once the Confirm Order message is sent, the Process Order interaction is initiated. This interaction is stored in another sequence diagram, and is represented here by an interaction reference:

Analyzing a Use Case

A sequence diagram can be used to refine a use case behavior or description. This approach is useful during requirement analysis because it may help identify classes and associations that did not emerge at the beginning.

You can formalize the association between the use case and the sequence diagram by adding the diagram to the Related Diagrams tab of the property sheet of the use case.

It is often necessary to create several diagrams to describe all the possible scenarios of a use case. In this situation, it can be helpful to use the sequence diagrams to discover all the pertinent objects before trying to identify the classes that will instantiate them. After having identified the classes, you can then deduce the associations between them from the messages passing between the objects.

Analyzing a Class Diagram

Building a sequence diagram can also be the opportunity to test a static model at the conception level; it may represent a scenario in which classes from the class diagram are instantiated to create the objects necessary to run the scenario.

It complements the class diagram that represents the static structure of the system by specifying the behavior of classes, interfaces, and the possible use of their operations.

A sequence diagram allows you to analyze class operations more closely than a communication diagram. You can create an operation in the class of an object that receives a message through the property sheet of the message. This can also be done in a communication diagram, but there is more space in a sequence diagram to display detailed information (arguments, return value, etc) about the operation.

Creating a Sequence Diagram

You can create a sequence diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Sequence Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Sequence Diagram**.

To create a new OOM with a sequence diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Sequence Diagram** as the first diagram, and click **OK**.

Note: The Auto-layout, Align and Group Symbols features are not available in the sequence diagram.

When you use the Merge Models feature to merge sequence diagrams, the symbols of all elements in the sequence diagram are merged without comparison. You can either accept all modifications on all symbols or no modifications at all.

Creating a Sequence Diagram from a Communication Diagram

You can create a sequence diagram from a communication diagram. The new sequence diagram reuses the objects and messages from the communication diagram. Right-click in the background of the communication diagram.

Select Create Default Sequence Diagram in the contextual menu.

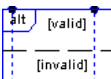

or

Select **Tools > Create Default Sequence Diagram**.

Sequence Diagram Objects

PowerDesigner supports all the objects necessary to build sequence diagrams.

Object	Tool	Symbol	Description
Actor			An external person, process or something interacting with a system, sub-system or class. See <i>Actors (OOM)</i> on page 13.

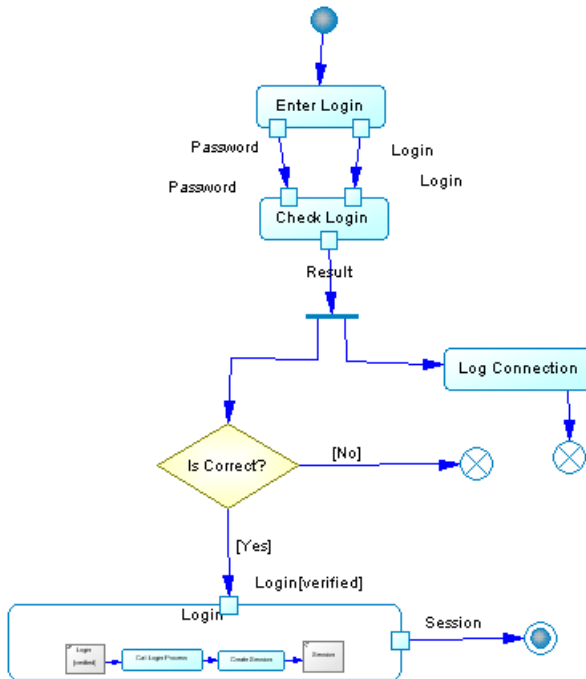

Object	Tool	Symbol	Description
Object			Instance of a class. See <i>Objects (OOM)</i> on page 55.
Activation			Execution of a procedure, including the time it waits for nested procedures to execute. See <i>Activations (OOM)</i> on page 152.
Interaction Reference			Reference to another sequence diagram. See <i>Interaction References and Interaction Activities (OOM)</i> on page 155.
Interaction Fragment			Collection of associated messages. See <i>Interaction Fragments (OOM)</i> on page 158.
Message			Communication that conveys information with the expectation that action will ensue. See <i>Messages (OOM)</i> on page 138.
Self Message			Recursive message: the sender and the receiver are the same object. See <i>Messages (OOM)</i> on page 138.
Procedure Call Message			Procedure call message with a default activation. See <i>Messages (OOM)</i> on page 138.
Self Call Message			Procedure call recursive message with a default activation. See <i>Messages (OOM)</i> on page 138.
Return Message			Specifies the end of a procedure. Generally associated with a Procedure Call, the Return message may be omitted as it is implicit at the end of an activation. See <i>Messages (OOM)</i> on page 138.
Self Return Message			Recursive message with a Return control flow type. See <i>Messages (OOM)</i> on page 138.

Activity Diagram Basics

An *activity diagram* is a UML diagram that provides a graphical view of a system behavior, and helps you functionally decompose it in order to analyze how it will be implemented.

Whereas a statechart diagram focuses on the implementation of operations in which most of the events correspond precisely to the end of the preceding activity, the activity diagram does not differentiate the states, the activities and the events.

The activity diagram gives a simplified representation of a process, showing control flows (called transitions) between actions performed in the system (called activities). These flows represent the internal behavior of a model element (use case, package, classifier or operation) from a start point to several potential end points.

You can create several activity diagrams in a package or a model. Each of those diagrams is independent and defines an isolated context in which the integrity of elements can be checked.

Analyzing a Use Case

An activity diagram is frequently used to graphically describe a use case. Each activity corresponds to an action step and the extension points can be represented as conditional branches.

Analyzing a Business Process

Beyond object-oriented modeling, activity diagrams are increasingly used to model the business processes of an enterprise. This kind of modeling takes place before the classic UML modeling of an application, and permits the identification of the important processes of the enterprise and the domains of responsibility of each organizational unit within the enterprise.

For more information about business process modeling with PowerDesigner, see the Business Process Modeling guide.

Activity Diagram Objects

PowerDesigner supports all the objects necessary to build activity diagrams.

Object	Tool	Symbol	Description
Start			Starting point of the activities represented in the activity diagram. See <i>Starts (OOM)</i> on page 182.
Activity			Invocation of an action. See <i>Activities (OOM)</i> on page 161.
Composite activity	N/A		Complex activity decomposed to be further detailed. See <i>Activities (OOM)</i> on page 161.
Object node			A specific state of an activity. See <i>Object Nodes (OOM)</i> on page 192.
Organization unit			A company, a system, a service, an organization, a user or a role. See <i>Organization Units (OOM)</i> on page 174.
Flow			Path of the control flow between activities. See <i>Flows (OOM)</i> on page 189.
Decision			Decision the control flow has to take when several flow paths are possible. See <i>Decisions (OOM)</i> on page 185.
Synchronization			Enables the splitting or synchronization of control between two or more concurrent actions. See <i>Synchronizations (OOM)</i> on page 187.
End			Termination point of the activities described in the activity diagram. See <i>Ends (OOM)</i> on page 183.

Creating an Activity Diagram

You can create an activity diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Activity Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Activity Diagram**.

To create a new OOM with an activity diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Activity Diagram** as the first diagram, and click **OK**.

Statechart Diagram Basics

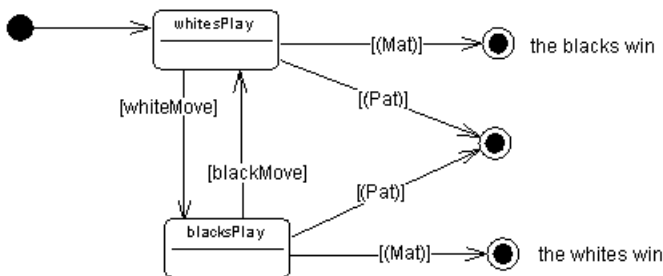

A *statechart diagram* is a UML diagram that provides a graphical view of a State Machine, the public behavior of a classifier (component or class), in the form of the changes over time of the state of the classifier and of the events that permit the transition from one state to another.

It is assumed that the classifier has previously been identified in another diagram and that a finite number of states can be identified for it.

Unlike the interaction diagrams, the statechart diagram can represent a complete specification of the possible scenarios pertaining to the classifier. At any given moment, the object must be in one of the defined states.

You can create several statechart diagrams for the same classifier, but then the states and transitions represented should relate to a different aspect of its evolution. For example; a person can be considered on one hand as moving between the states of studying, working, being unemployed, and being retired, and on the other as transitioning between being single, engaged, married, and divorced.

Statechart diagrams show classifier behavior through execution rules explaining precisely how actions are executed during transitions between different states; these states correspond to different situations during the life of the classifier.

The example above shows the states of a game of chess.

The first step in creating a statechart diagram consists in defining the initial and final states and the set of possible states between them. Then you link the states together with transitions, noting on each, the event that sets off the transition from one state to another.

You can also define an action that executes at the moment of the transition. Similarly, the entry to or exit from a state can cause the execution of an action. It is even possible to define the internal events that do not change the state. Actions can be associated with the operations of the classifier described by the diagram.

It is also possible to decompose complex states into sub-states, which are represented in sub-statechart diagrams.

A statechart diagram requires the previous identification of a classifier. It can be used to describe the behavior of the classifier, and also helps you to discover its operations via the specification of actions associated with statechart events.

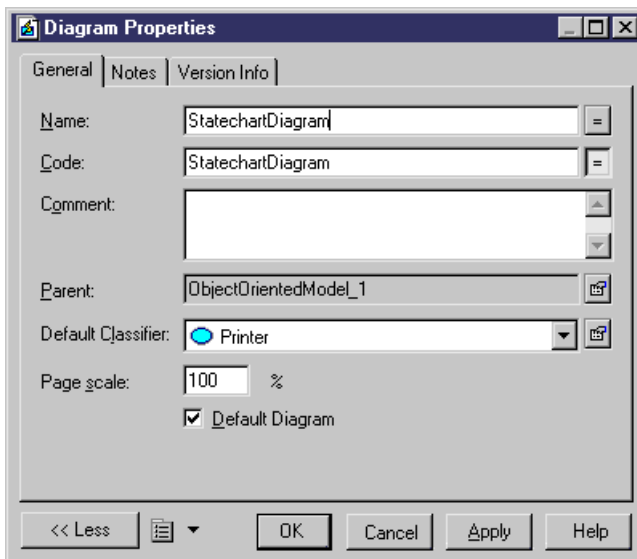

You can also use the transitions identified to establish the order in which operations can be invoked. This type of diagram is called a "protocol state machine".

Another potential use is the specification of a Graphic User Interface (GUI) where the states are the distinct screens available with possible transitions between them, all depending on keyboard and mouse events produced by the user.

Defining a Default Classifier in the Statechart Diagram

You can define the classifier of a state using the Classifier list in the state property sheet. This allows you to link the state to a use case, a component or a class.

At the diagram level, you can also specify the context element of a state by filling in the Default Classifier list in the statechart diagram property sheet. As a result, each state that is created in a diagram using the State tool is automatically associated with the default classifier specified in the statechart diagram property sheet.

By default new diagrams are created with an empty value in the Default Classifier list, except sub-statechart diagrams that automatically share the same Classifier value defined on the parent decomposed state. The Default Classifier value is an optional value in the statechart diagram.

For general information about diagram properties, see "Diagram properties" in the Diagrams and Symbols chapter of the *Core Features Guide*.

Statechart Diagram Objects

PowerDesigner supports all the objects necessary to build statechart diagrams.

Object	Tool	Symbol	Description
Start			Starting point of the states represented in the statechart diagram. See <i>Starts (OOM)</i> on page 182.
State			The situation of a model element waiting for events. See <i>States (OOM)</i> on page 194.
Action	N/A	N/A	Specification of a computable statement. See <i>Actions (OOM)</i> on page 204.
Event	N/A	N/A	Occurrence of something observable, it conveys information specified by parameters. See <i>Events (OOM)</i> on page 201.
Transition			Path on which the control flow moves between states. See <i>Transitions (OOM)</i> on page 199.
Junction point			Divides a transition between states. Used particularly when specifying mutually exclusive conditions. See <i>Junction Points (OOM)</i> on page 207.
Synchronization			Enables the splitting or synchronization of control between two or more concurrent states. See <i>Synchronizations (OOM)</i> on page 187.
End			Termination point of the states described in the statechart diagram. See <i>Ends (OOM)</i> on page 183.

Creating a Statechart Diagram

You can create a statechart diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Statechart Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Statechart Diagram**.

To create a new OOM with a statechart diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Statechart Diagram** as the first diagram, and click **OK**.

Interaction Overview Diagram Basics

An *interaction diagram* is a UML diagram that provides a high-level graphical view of the control flow of your system as it is decomposed into sequence and other interaction diagrams.

You can include references to sequence diagrams, communication diagrams, and other interaction diagrams.

In the following example, a control flow is shown linking two sequence diagrams:

Interaction Overview Diagram Objects

PowerDesigner supports all the objects necessary to build interaction overview diagrams.

Object	Tool	Symbol	Description
Start			Starting point of the interactions represented in the diagram. See <i>Starts (OOM)</i> on page 182.
Interaction activity			Reference to a sequence diagram, communication diagram, or interaction overview diagram. See <i>Interaction References and Interaction Activities (OOM)</i> on page 155.
Flow			Flow of control between two interactions. See <i>Flows (OOM)</i> on page 189.
Decision			Decision the flow has to take when several paths are possible. See <i>Decisions (OOM)</i> on page 185.
Synchronization			Enables the splitting or synchronization of control between two or more flows. See <i>Synchronizations (OOM)</i> on page 187.
End			Termination point of the interactions described in the diagram. See <i>Ends (OOM)</i> on page 183.

Creating an Interaction Overview Diagram

You can create an interaction overview diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Interaction Overview Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Interaction Overview Diagram**.

To create a new OOM with an interaction overview diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Interaction Overview Diagram** as the first diagram, and click **OK**.

Messages (OOM)

A *message* is a communication between objects. The receipt of a message will normally have an outcome.

A message can be created in the following diagrams:

- Communication Diagram
- Sequence Diagram

Objects can cooperate by using several kinds of requests (send a signal, invoke an operation, create an object, delete an existing object, etc.). Sending a signal is used to trigger a reaction from the receiver in an asynchronous way and without a reply. Invoking an operation will apply an operation to an object in a synchronous or asynchronous mode, and may require a reply from the receiver. All these requests constitute *messages*. They correspond to stimulus in the UML language.

A message has a sender, a receiver, and an action. The *sender* is the object or actor that sends the message. The *receiver* is the object or actor that receives the message. The action is executed on the receiver. You can also create recursive messages, where the same object is the sender and receiver.

The message symbol is an arrow showing its direction, and can also display the following information:

- A sequence number indicating the order in which messages are exchanged (see *Sequence numbers* on page 149)
- The message name (or the name of the associated operation)
- The condition
- The return value
- The argument

Reusing Messages

The same message can be used in a sequence and a communication diagram or in multiple diagrams of either type. When you drag a message from one diagram to another, it is dropped with both extremities if they do not exist, and (in a communication diagram) it is attached to a default instance link.

The sequence number attached to a message is identical in all diagrams if the message is reused.

When you copy a message, its name does not change. You can either keep its original name, or rename the message after copy.

Any change on the Action or Control Flow value of the message is reflected in all diagrams. However, if the change you want to perform is not valid, the change will not be possible. For example, you are not allowed to move a Create message if a Create message already exists between the sender and the receiver.

Messages in a Communication Diagram

In a communication diagram, each message is associated with an instance link. An instance link may have several associated messages, but each message can be attached to only one instance link. The destruction of an instance link destroys all the messages associated with it.

Messages in a Sequence Diagram

A message is shown as a horizontal solid arrow from the lifeline of one object or actor, to the lifeline of another. The arrow is labeled with the name of the message. You can also define a *control flow type* that represents both the relationship between an action and its preceding and succeeding actions, and the waiting semantics between them.

In a sequence diagram you can choose between the following types of messages:

- Message
- Self Message
- Procedure Call Message
- Self Call Message
- Return Message
- Self Return Message

You can create activations on the lifeline of an object to represent the period of time during which it is performing an action.

A message can be drawn from an actor to an object, or inversely. It is also possible to create a message between two actors but it will be detected, and displayed as a warning during the check model process.

Note: If you need to fully describe, or put a label on a message, you can write a note using the Note tool, and position the note close to the message.

Creating a Message

You can create a message in any of the following ways:

- Use the Message tool (or, in a sequence diagram, the Self Message, Procedure Call Message, or Self Call Message tool) in the diagram Palette
- Select **Model > Messages** to access the List of Messages, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Message**
- Open the property sheet of an instance link (in a communication diagram), click the Messages tab, and click the Create a New Message tool.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Message Properties

You can modify an object's properties from its property sheet. To open a message property sheet, double-click its diagram symbol or its Browser entry in the Messages folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for use cases.

A message has the following general properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the message
Sequence number	Allows you to manually add a sequence number to the message. It is mainly used in communication diagrams to describe the order of messages, but can also be used in sequence diagrams
Stereotype	Extends the semantics of the object beyond the core UML definition.
Sender	Object the message starts from. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.

Property	Description
Receiver	Object the message ends on. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object. Click the Reverse direction tool beside this box to invert the sender and receiver. You cannot invert the direction of a message when the message is a Create or Destroy message.

Note: You can right-click a message in the diagram and select Reverse from the contextual menu to invert its direction.

Message Property Sheet Detail Tab

The Detail tab in the message property sheet includes the following properties:

Property	Description
Action	<p>Specifies the type of message action. You can choose between:</p> <ul style="list-style-type: none"> • Create – the sender object instantiates and initializes the receiver object. A message with a create action is the first message between a sender and a receiver. • Destroy – the sender object destroys the receiver object. A large X is displayed on the lifeline of the receiver object. A message with a destroy action is the last message between a sender and a receiver. • Self-Destroy – (only available if the control flow property is set to "Return") the sender object warns the receiver object that it is destroying itself. A large X is displayed on the lifeline of the sender object. A message with a self-destroy action is the last message between a sender and a receiver.
Control flow	<p>Specifies the mode in which messages are sent. You can choose between:</p> <ul style="list-style-type: none"> • Asynchronous – the sending object does not wait for a result, it can do something else in parallel. <i>No-wait semantics</i> • Procedure Call – Call of a procedure. The sequence is complete before the next sequence resumes. The sender must wait for a response or the end of the activation. <i>Wait semantics</i> • Return – Generally associated with a Procedure Call. The Return arrow may be omitted as it is implicit at the end of an activation • Undefined – No control flow defined

Property	Description
Operation	<p>Links the message to an operation of a class. If the receiver of a message is an object, and the object has a class, the message, as a dynamic flow of information, invokes an operation. You can therefore link a message to an existing operation of a class but also operations defined on parent classes, or you can create an operation from the Operation list in the message property sheet.</p> <p>If an operation is linked to a message, you can replace the message name with the name of the method that one object is asking the other to invoke. This process can be very useful during implementation. To display the name of the operation instead of the name of the message, select the Replace by Operation Name display preference in the message category.</p> <p>You can link a Create message to a Constructor operation of a class if you wish to further detail a relation between a message and an operation. You are not allowed however to link a message with a Return control flow to an operation.</p> <p>If you change the generalization that exists between classes, the operation that is linked to the message may no longer be available. In this case, the operation is automatically detached from the message. The same occurs when you reverse the message direction, unless the new receiver object has the same class.</p>
Arguments	Arguments of the operation
Return value	Function return value stored in a variable and likely to be used by other functions
Predecessor list	Made of a list of sequence numbers followed by "/", the predecessor list defines which messages must be exchanged before the current message could be sent. Example: sequence numbers 1, 2, 4 before 3 = "1,2,4/ 3"
Condition	Condition attached to the message. May be specified by placing Boolean expressions in braces on the diagram. Example: condition for timing: [dialing time < 30 sec]
Begin time	User-defined time alias, used for defining constraints. Example: Begin time = t1, End time = t2, constraint = {t2 - t1 < 30 sec}
End time	User-defined time alias, used for defining constraints.
Support delay	<p>Specifies that the message may have duration. The message symbol may slant downwards.</p> <p>If this option is not selected, the message is instantaneous, or fast, and the message symbol is horizontal.</p> <p>You can specify Support delay as a default option in the Model Options dialog box.</p> <p>Support delay is not available with a recursive message: it is selected and grayed out.</p>

Control Flow

By default, a message has an Undefined control flow.

If you want to make a diagram more readable, you can draw the Return arrow to show the exact time when the action is returned back to the sender. It is an explicit return that results in returning a value to its origin.

In the example below, the explicit Return causes values to be passed back to the original activation.

You can combine message control flows and message actions according to the following table:

Control flow	Symbol	No action	Create	Destroy	Self-Destroy
Asynchronous	—>				—
Procedure Call	—>				—
Return	- ->		—	—	
Undefined	—>				—

= allowed

— = not allowed

Note: You can access the Action and Control flow values of a message by right clicking the message symbol in the diagram, and selecting Action/Control flow from the contextual menu.

Creating Create and Destroy Messages in a Sequence Diagram

Create and Destroy messages are specified via the Action property on the Detail tab of their property sheet.

Creating Create Messages

A message can create an object if it is the first message received by the object and you set its Action property to "Create".

You cannot create an actor or use the create action with a recursive message.

When a message creates an object in a sequence diagram, the message is drawn with its arrowhead on the object; both object and message are at the same level.

In a sequence diagram, you can also create a create message automatically as follows:

1. Click the Message tool in the Palette.
2. Click the lifeline of the sender object or actor and, while holding down the mouse button, drag the cursor towards the receiver object.
3. Release the mouse button on the object symbol of the receiver (and not on its lifeline).

If the message is the first message to be received by the receiver object, the receiver object symbol moves down to line up with the create message.

Creating Destroy Messages

A message can destroy an object if it is the last message received by the object and you set its Action property to "Destroy".

You cannot destroy an actor or use the destroy action with a recursive message.

A destroyed object lifeline is marked by an X at the intersection point between the object lifeline and the message. The Destroy action ends both activation and object lifeline at this same point.

Note that the Destroy action does not destroy the object, but only represents this destruction in the diagram. The object lifeline ends at a precise point in time; it is not possible to graphically pull the lifeline downwards any more.

There are two possible forms of destroy messages:

- Destroy message
- Self-Destroy message

Creating a Destroy Message

To create a destroy message:

1. Click the Message tool in the Palette.
2. Click the lifeline of the sender object or actor and, while holding down the mouse button, drag the cursor towards the lifeline of the receiver object.
3. Release the mouse button on the lifeline of the receiver, and then double-click the newly created message symbol to display its property sheet.
4. Select Destroy from the Action list in the Detail tab (this action is not available if the message is not the last message on the receiver lifeline).
5. Click OK. An X is placed at the intersection point between the Destroy message arrow and the receiver object lifeline.

**Creating a Self-Destroy Message**

To create a self-Destroy Message:

1. Click the Message tool in the Palette.
2. Click the lifeline of the sender object and, while holding down the mouse button, drag the cursor towards the lifeline of the receiver object.
3. Release the mouse button on the object symbol of the receiver, and then double-click the newly created message symbol to display its property sheet.
4. Select Self-Destroy from the Action list in the Detail tab.
5. Select Return from the Control flow list.
6. Click OK. The lifeline of the self-destroyed object is marked by an X.

Creating a Recursive Message in a Sequence Diagram

A message is recursive when the object sends the message to itself. In this case, the arrow starts and finishes on the lifeline of the same object.

The Create and Self-Destroy actions, and the Support delay option are not available with a recursive message.

When you create Undefined or Return recursive messages from the tool palette, the control flow value is already selected:

Message type	Symbol
Undefined recursive message	
Return recursive message	

You can also create an Undefined recursive message and change the control flow value afterwards.

Example

You can choose to create a recursive message with or without activation from the tool palette.

When you create a recursive message with activation, the recursive message is automatically attached to an activation and its control flow value is a Procedure Call which, by default, starts the activation.

Activation symbols are automatically created on the object lifeline as shown below:

Creating a Recursive Message Without Activation

To create a recursive message without activation:

1. Click the Self Message tool in the palette.
2. Click the object lifeline to create a recursive message.

Creating a Recursive Message with Activation

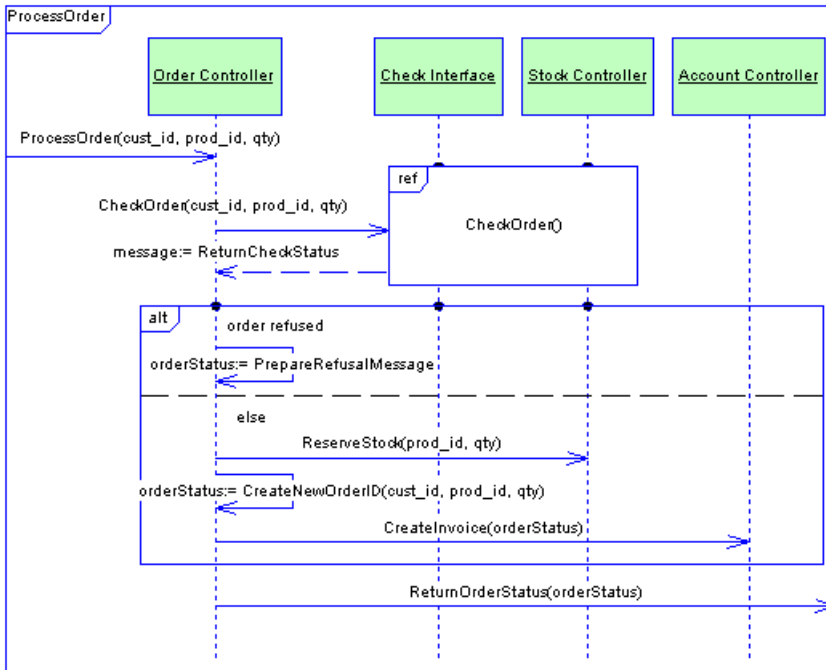

To create a recursive message with activation:

1. Click the Self Call Message tool in the palette.
2. Click the object lifeline to create a recursive message with activation.

Messages and Gates

In UML 2, you can send messages to and from the interaction frame that surrounds your sequence diagram. The frame represents the outer edge of the system (or of the part of the system) being modeled and can be used in place of an actor (actors are no longer used in UML 2 sequence diagrams, but continue to be supported for backwards compatibility in PowerDesigner). A message originating from a point on the frame is said to be sent from an *input gate*, while a message arriving there is received by an *output gate*.

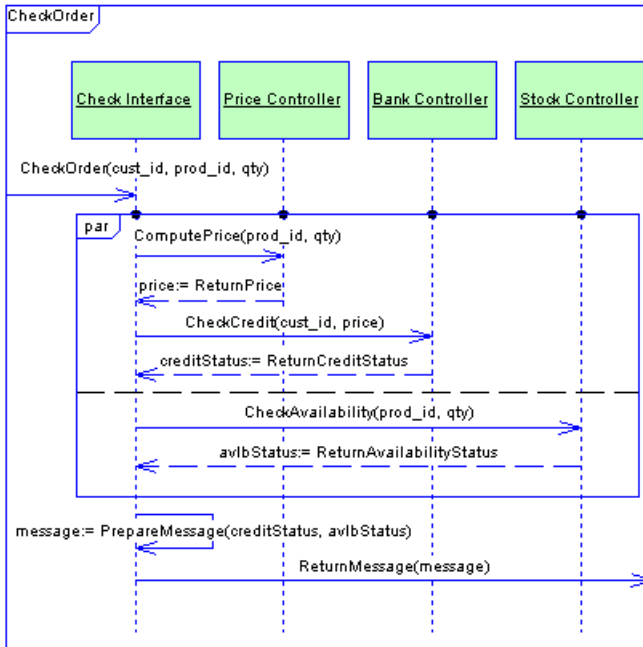

In the example below, a high-level sequence diagram, ProcessOrder, shows a series of communications between a user and an sales system:

The message ProcessOrder originates from an input gate on the ProcessOrder interaction frame, and is received as an input message by the Order Controller object. Once the order processing is complete, the message ReturnOrderStatus is received by an output gate on the ProcessOrder interaction frame.

The message CheckOrder originates from the Order Controller object, and is received as an input message by an input gate on the CheckOrder interaction reference frame. Once the order checking is complete, the ReturnCheckStatus message is sent from an output gate on the CheckOrder interaction reference frame and is received by the Order Controller object.

The following diagram shows the CheckOrder sequence diagram which illustrates the detail of the order checking process:

Here, the message **CheckOrder** originates from an input gate on the **CheckOrder** interaction frame, and is received as an input message by the **Check Interface** object. Once the order processing is complete, the message **ReturnMessage** is received by an output gate on the **CheckOrder** interaction frame.

Note: PowerDesigner allows you to use actors and interaction frames in your diagrams in order to provide you with a choice of styles and to support backwards compatibility. However, since both represent objects exterior to the system being modeled, we recommend that you do intermingle actors and frames in the same diagram. You cannot send messages between an actor and an interaction frame.

Sequence Numbers

Sequence numbers can be assigned to messages in both communication and sequence diagrams, but they are most important in communication diagrams.

When you create a message in a communication diagram, the default value of the sequence number is calculated with regards to the most recently created or modified message. The first sequence number created is 1.

A succession of sequence numbers is built from the most recent sequence number plus 1. For example, $3 + 1 \Rightarrow 4$, or $2.1 + 1 \Rightarrow 2.2$

The creation of sequence numbers respects the syntax of numbers already used in the diagram (1, 2, 3, etc... or 1.1, 1.2, etc.).

By convention, the addition of letters to sequence numbers signifies that the messages are parallel. For example, the messages with sequence numbers 3.1a and 3.1b are sent at the same time.

If you need to change sequence numbers manually, you can move or insert messages in the diagram or increase and decrease the sequence numbers.

Moving Sequence Numbers

You can move and insert message numbers within the communication diagram.

When you move an existing number and attach it to another message, the sequence numbers are recalculated with respect to the following rules:

- For a number "x", all numbers equal to or greater than number "x" are modified
- Any gap is filled with the sequence number that is immediately available after the move

Example 1

The sequence numbers in a communication diagram are 1, 2, 3, 4, 5, and 6.

When you change sequence number 6 and place it in third position, sequence number 6 becomes sequence number 3: all numbers between 3 and 6 are modified as follows:

Example 2

When you change sequence number 4 and place it in second position, sequence number 4 becomes sequence number 2: all numbers between 2 and 4 are modified, 5 and 6 remain:

Example 3

When you change sequence number 2 and place it in fifth position, sequence number 2 becomes sequence number 5: all numbers between 2 and 5 are modified as follows:

Example 4

The sequence numbers in a communication diagram are:

- 1
- 1.1:msg_a
- 1.1.1:msg_a1
- 1.1.2:msg_a2
- 1.2:msg_b
- 2
- 3

When you change sequence number 1.1:msg_a to sequence number 3, the following changes occur:

Note: You can use the Undo feature whenever needed while manipulating these elements within communication diagrams.

Inserting Sequence Numbers

When you insert a new message with a new sequence number in an existing communication diagram, the sequence numbers are recalculated with respect to the following rule: for each number after the insertion, all numbers are incremented by 1.

In the same manner, a parent changes its children. For example, the number is incremented by 1 for numbers like 1.1, 1.2, 1.3 as follows: $1.1 + 1 = 1.2$.

The syntax of sequence numbers currently used in the diagram is respected: that means that the number is incremented by 1 regardless of the syntax (1, 2, 3... or 1.1, 1.2, 1.3...).

Increasing Sequence Numbers in a Communication Diagram

You can increment a sequence number using the following methods:

- Right-click the message in the diagram and select Increase Number from the contextual menu.

or

Select the message in the diagram and press ctrl and the numpad + sign to increment the number by 1.

Decreasing Sequence Numbers in a Communication Diagram

You can decrease a sequence number using the following methods:

- Right-click the message in the diagram and select Decrease Number from the contextual menu.

or

Select the sequence number in the diagram and press ctrl and + sign to decrease the number by 1.

Activations (OOM)

Activations are optional symbols that represent the time required for an action to be performed. They are created on the lifeline of an object. They are purely symbols and do not have property sheets.

An activation can be created in the following diagrams:

- Sequence Diagram

In a communication diagram, messages that are passed during the period represented by an activation are given sub-numbers. Thus an activation created by message 1, may give rise to messages 1.1 and 1.2.

You can attach or detach a message to an activation. You can also move, resize, and cause the activation to overlap other activations.

Creating an Activation

You can create an activation when you create a Procedure Call message or afterwards for any type of message. A Procedure Call generally starts an activation, that is why the message is automatically attached to an activation.

Creating an Activation at Creation of the Message

To create an activation at creation of the message:

1. Select the Procedure Call Message tool in the Palette.
2. Click the lifeline of the sender object or actor and, while holding down the mouse button, drag the cursor towards the receiver object.
3. Release the mouse button on the object symbol of the receiver.

The message is created along with activations on the lifelines of both the sender and receiver (note that activations are not created on the lifelines of actors).

Creating an Activation from a Diagram:

To create an activation from a diagram:

1. Select the Activation tool in the Palette.
2. Click the lifeline of an object to create an activation symbol at the click position. If you create the activation on top of an existing message, it is automatically attached to the activation.

Attaching a Message to an Activation

A message is attached to an activation when its begin or endpoint is on the activation symbol and not on the object lifeline. Attachment symbols appear at the endpoints of the message arrow (if attachment symbols are not displayed, select **Tools > Display Preferences**, and select the Activation Attachment display preference in the Message category).

You can attach an existing message that touches an activation but which does not display an activation symbol, by dragging the message inside the activation, while holding the ctrl key down.

When a message is attached to an activation, you cannot move it outside the limits of the activation symbol as shown below:

If you delete an activation with a message attached, the message will be detached from the activation but will not be deleted.

Message Control Flow and Activation

When a message is attached to an activation, the control flow value of the message influences the position of the activation towards the message:

- Procedure Call - A Procedure Call message attached to an activation starts the activation on the receiver lifeline, that is to say the arrival point of the message is located at the top of the activation.
- Return - A Return message attached to an activation finishes the activation on the sender lifeline, that is to say the starting point of the message is located at the bottom of the activation.

Procedure Call and Return messages are the only messages defined on a definite location in the activation: a Procedure Call message is at the top of the activation, a Return message is at

the bottom of the activation. Other messages attached to an activation can be moved without any constraint inside the activation.

Detaching a Message from an Activation

You can detach a message from an activation by dragging the message outside the activation, while holding the ctrl key down.

Overlapping Activations

An activation can overlap other existing activations.

For example, you may want an activation to overlap another one to represent an action in a loop. The action is done repeatedly until it reaches its goal, this loop can start and finish at the same time another activation is representing another action.

You can make activations overlap this way to show concurrent activities.

Moving an Activation

If you move an activation with a message attached to it, the message does not move. Thus, it is possible to move the activation up and down until its top or bottom reaches the message level.:

If you move the endpoint of a message with Support Delay, the inclination angle of the message is preserved as shown below:

Resizing an Activation

You may want to resize an activation by pulling the top or bottom of the activation symbol. This will resize the activation vertically.

When you resize an activation, the following rules apply:

- A Procedure Call message is always attached to the top of the activation on the receiver lifeline. The Procedure Call message stays at the top of the activation if the activation is moved up, or resized upwards.
- A Return message is always attached to the bottom of the activation on the sender lifeline. The Return message stays at the bottom of the activation if the activation is moved down.
- Messages that are covered by the activation after resizing are not automatically attached to the activation.

To change the activation of a message, press ctrl and click to select the begin or endpoint of the message and drag it onto another activation.

Interaction References and Interaction Activities (OOM)

An interaction reference is used to represent one sequence diagram in the body of another. This feature allows you to modularize and reuse commonly-used interactions across a range of sequence diagrams.

An interaction reference can be created in the following diagrams:

- Sequence Diagram

Interaction activities are similar, but are able to represent a sequence diagram, communication diagram, or interaction overview diagram. Interaction activities can be created in the following diagrams:

- Sequence Diagram

For an interaction activity, right-click the activity and select **Composite View > Read-only (Sub-Diagram)** to see the referenced diagram displayed in the symbol. Select **Adjust to read-only view** from the contextual menu to automatically resize the symbol to optimize the display of the referenced diagram.

Example: Interaction Reference in Activity Diagram

In the example below, the user must log in before passing a request to the account page of a website. As the log in process will form a part of many interactions with the site, it has been abstracted to another sequence diagram called "Log In", and is represented here by an interaction reference.

Creating an Interaction Reference

You can create an interaction reference in any of the following ways:

- Use the Interaction Reference tool in the diagram Palette. You can either click near the lifeline of an object to create an interaction reference attached to that lifeline, or click and hold while drawing a box that will overlap and attach to several lifelines. The Select a sequence diagram dialog box opens to allow you to specify the sequence diagram to which the reference refers. Select an existing or new diagram and click OK.
- Drag another sequence diagram from the browser and drop it into the present sequence diagram.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Creating an Interaction Activity

You can create an interaction activity in any of the following ways:

- Use the Interaction Activity tool in the diagram Palette.

The Select a diagram dialog box opens to allow you to specify the diagram to which the activity refers. Select an existing or new diagram and click OK.

- Drag a sequence, communication or interaction overview diagram from the browser and drop it into an interaction overview diagram.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Interaction Reference and Interaction Activity Properties

You can modify an object's properties from its property sheet. To open an interaction reference property sheet, double-click its diagram symbol in the top-left corner near the operator tag.

The General Tab contains the following properties:

Property	Description
Referenced Diagram	Specifies the sequence diagram that will be represented in the current diagram by the interaction reference. You can click on the Create tool to the right of the box to create a new sequence diagram.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Arguments	Specifies the arguments to be passed to the first message in the referenced diagram.
Return value	Specifies the value to be returned by the last message in the referenced diagram.

Manipulating Interaction References

You can move interaction references, resize them, and generally manipulate them freely.

When you cause the symbol to overlap an object lifeline, it attaches to it automatically, and this attachment is represented by a small bump on the top edge of the symbol where it meets the lifeline. If you drag or resize the symbol away from a lifeline, it detaches automatically.

If you move an object that is attached to an interaction, the symbol resizes itself automatically to remain attached to the object lifeline.

You can manually control whether object lifelines are attached to an interaction reference that passes over them by clicking the attachment point.

Note that an interaction reference cannot be copied or re-used in another diagram. However, multiple references to the same diagram can be created.

Interaction Fragments (OOM)

An interaction fragment allows you to group related messages in a sequence diagram. Various predefined fragment types are available allowing you to specify alternate outcomes, parallel messages, or looping.

An interaction fragment can be created in the following diagrams:

- Sequence Diagram

In the example below, the User sends a request to the Account Page. The two alternative responses and the conditions on which they depend, are contained within an interaction fragment.

Creating an Interaction Fragment

You can create an interaction fragment as follows:

- Use the Interaction Fragment tool in the diagram Palette. You can either click near the lifeline of an object to create an interaction fragment attached to that lifeline, or click and hold while drawing a box that will overlap and attach to several lifelines.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Interaction Fragment Properties

You can modify an object's properties from its property sheet. To open an interaction fragment property sheet, double-click its diagram symbol in the top-left corner near the operator tag.

The following sections detail the property sheet tabs that contain the properties most commonly entered for interaction fragments.

The General Tab contains the following properties:

Property	Description
Operator	<p>Specifies the type of fragment. You can choose between:</p> <ul style="list-style-type: none"> • Alternative (alt) – the fragment is split into two or more mutually exclusive regions, each of which has an associated guard condition. Only the messages from one of these regions will be executed at runtime. • Assertion (assert) – the interaction must occur exactly as indicated or it will be invalid. • Break (break) – if the associated condition is true, the parent interaction terminates at the end of the fragment. • Consider (consider) – only the messages shown are significant. • Critical Region (critical) – no other messages can intervene until these messages are completed. • Ignore (ignore) – some insignificant messages are not shown. • Loop (loop) – the interaction fragment will be repeated a number of times. • Negative (neg) – the interaction is invalid and cannot happen. • Option (opt) – the interaction only occurs if the guard condition is satisfied. • Parallel (par) – the fragment is split into two or more regions, all of which will be executed in parallel at runtime. • Strict Sequencing (strict) – the ordering of messages is strictly enforced. • Weak Sequencing (seq) – the ordering of messages is enforced on each lifeline, but not between lifelines. <p>The operator type is shown in the top left corner of the interaction fragment symbol.</p>
Stereotype	Extends the semantics of the object beyond the core UML definition.
Condition	<p>Specifies any condition associated with the fragment. This may be the evaluation of a variable, such as:</p> <p>$X > 3$</p> <p>Or, for a loop fragment, the specification of the minimum and (optionally) maximum number of times that the loop will run. For example:</p> <p>1,10</p> <p>For the Consider or Ignore operators, this field lists the associated messages.</p> <p>This field is not available if the fragment does not support conditions.</p>

Interaction Fragment Property Sheet Sub-Regions Tab

The Interaction Sub-Regions Tab lists the regions contained within the fragment. It is only displayed if you select an operator that requires more than one region.

You can add or delete regions and (if appropriate) specify conditions for them.

Manipulating Interaction Fragments

You can manipulate interaction fragments with some limitations.

Moving and Resizing Fragments

You can move interaction fragments, resize them, and generally manipulate them freely. When you cause the symbol to overlap an object lifeline, it attaches to it automatically, and this attachment is represented by a small bump on the top edge of the symbol where it meets the lifeline. If you drag or resize the symbol away from a lifeline, it detaches automatically.

If you move an object that is attached to an interaction fragment, the symbol resizes itself automatically to remain attached to the object lifeline.

You can manually control whether object lifelines are attached to an interaction fragment that passes over them by clicking the attachment point.

Moving Messages

Any message that is entirely enclosed within an interaction fragment will be moved with the fragment up and down the object lifeline to which it is attached. However, if you move the fragment away from either of the lifelines to which it is attached, the message will be detached from the fragment and not moved.

You can move messages freely in and out of interaction fragments. If you move a message so that it is completely contained within a fragment, it will be attached to that fragment. If you move a message so either of its ends is outside the fragment, then it is detached from the fragment.

Messages and Regions

When a fragment is split into two or more regions, you can move messages freely between regions. However, you cannot move the dividing line between two regions over a message. You can resize a region by moving the dividing line below it. Such resizing will affect the total size of the fragment. To resize the last region, at the bottom of the fragment, you must select and move the bottom edge of the fragment.

If you delete a region, then the space that it occupied and any messages it contained will be merged with the region above.

Note that an interaction fragment cannot be copied as a shortcut in another diagram.

Activities (OOM)

An *activity* is the invocation of a manual or automated action, such as "send a mail", or "increment a counter". When the activity gains control, it performs its action and then, depending on the result of the action, the transition (control flow) is passed to another activity.

An activity can be created in the following diagrams:

- Activity Diagram

PowerDesigner's support for UML 2 allows you a great deal of flexibility in the level of detail you provide in your activity diagrams. You can simply link activities together to show the high-level control flow, or refine your model by specifying the:

- parameters that are passed between the activities (see *Specifying activity parameters* on page 164)
- action type of the activity and associate it with other model objects (see *Specifying action types* on page 165)

In the example above, the ReceiveCheckLogin activity has an action type of "Accept call" (see *Specifying action types* on page 165), and passes the two output parameters "login" and "password" (see *Specifying activity parameters* on page 164) to a series of decisions that lead to the ReplyCheckLogin. This last activity has an input parameter called "Result" and an action type of Reply Call.

Atomic and Decomposed Activities

An activity can be atomic or decomposed. Decomposed activities contain sub-activities, which are represented in a sub-diagram. For more information, see *Decomposed activities and sub-activities* on page 171.

A PowerDesigner activity is equivalent to a UML activity (ActionState or SubactivityState) and an activity graph. In UML, an ActionState represents the execution of an atomic action, and the SubactivityState is the execution of an activity graph (which is, in turn, the description of a complex action represented by sub-activities).

The following table lists the mappings between UML and PowerDesigner terminology and concepts:

UML Objects	PowerDesigner Objects
ActionState	Activity
SubactivityState	Composite activity
Activity Graph	Composite activity

PowerDesigner combines a SubactivityState and an activity graph into a decomposed activity so that you can define sub-activities directly under the parent without defining an additional object. If you do need to highlight the difference, you can create activities directly under the model or the package, and use activity shortcuts to detail the activity implementation, so that the SubactivityState corresponds to the shortcut of a decomposed activity.

Creating an Activity

You can create an activity in any of the following ways:

- Use the Activity tool in the diagram Palette
- Select **Model > Activities** to access the List of Activities, and click the Add a Row tool
- Right-click the model, package, or decomposed activity in the Browser, and select **New > Activity**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Activity Properties

You can modify an object's properties from its property sheet. To open an activity property sheet, double-click its diagram symbol or its Browser entry in the Activities folder. The

following sections detail the property sheet tabs that contain the properties most commonly entered for activities.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Organization unit	<p>Specifies the organization unit (see <i>Organization Units (OOM)</i> on page 174) linked to the activity and also allows you to assign the Committee Activity value (see <i>Displaying a committee activity</i> on page 176) to a decomposed activity to graphically show the links between organization units designed as swimlanes and sub-activities. A Committee Activity is an activity realized by more than one organization unit.</p> <p>You can click the Ellipsis button beside the Organization unit list to create a new organization unit or click the Properties tool to display its property sheet.</p>
Composite status	<p>Specifies whether the activity is decomposed into sub-activities. You can choose between:</p> <ul style="list-style-type: none"> • Atomic Activity – (default) The activity does not contain sub-activities • Decomposed Activity – the activity can contain sub-activities. A Sub-Activities tab is displayed in the property sheet to list these sub-activities, and a sub-diagram is created below the activity in the Browser to display them. <p>If you revert the activity from Decomposed to Atomic status, then any sub-activities that you have created will be deleted.</p>

Activity Property Sheet Action Tab

The Action tab defines the nature, the type and the duration of an action that an activity executes. It contains the following properties:

Property	Description
Action type	Specifies the kind of action that the activity executes. For more information, see <i>Specifying action types</i> on page 165.
[action object]	Depending on the action type you choose, an additional field may be displayed, allowing you to specify an activity, classifier, attribute, event, expression, operation, or variable upon which the action acts. You can use the tools to the right of the list to create an object, browse the available objects or view the properties of the currently selected object.

Property	Description
Pre-Conditions / Actions / Post-Conditions	These sub-tabs provide a textual account of how the action is executed. For example, you can write pseudo code or information on the program to execute.
Duration	Specifies the estimated or statistic duration to execute the action. This information is for documentation purposes only; estimate on the global duration is not computed.
Timeout	Zero by default. If the value is not set to zero, it means that a timeout exception occurs if the execution of the activation takes more than the specified timeout limit. You can type any alphanumeric value in the Timeout box (example: 20 seconds).

Activity Property Sheet Input Parameters and Output Parameters Tabs

These tabs list the input and output parameters required by the activity.

For more information, see *Specifying activity parameters* on page 164.

Activity Property Sheet Sub-Activities Tab

This tab is displayed only if the Composite status of the activity is set to Decomposed, and lists its sub-activities.

Specifying Activity Parameters

Activity parameters are values passed between activities. They are represented as small squares on the edges of activity symbols. In the example below, the parameters login and password are passed from the Enter login activity to the Check login activity:

1. Open the property sheet of an activity and click the Input Parameters or Output Parameters tab.
2. Use the tools to add an existing parameter or to create a new one.

Note: You can also create parameters as a part of specifying an activity action type. See *Specifying action types* on page 165.

Activity parameters can have the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Data type	Specifies the data type of the parameter. You can choose a standard data type or specify a classifier. You can use the tools to the right of the list to create a classifier, browse the available classifiers or view the properties of the currently selected classifier.
State	Specifies the object state linked to the parameter. You can enter free text in the field, or use the tools to the right of the list to create a state, browse the available states or view the properties of the currently selected state.

Specifying Action Types

You can add additional detail to your modeling of activities by specifying the type of action performed and, in certain cases, associating it with a specific model object that it acts upon, and the parameters that it passes.

1. Open the property sheet of an activity and click the Action tab.
2. Select an action type. The following list details the available action types, and specifies where appropriate, the required action object:
 - *<Undefined>* [no object] - default. No action defined
 - *Reusable Activity* [no object] – a top-level container.
 - *Call*[operation or activity] – calls an operation or activity. See *Example: Using the Call action type* on page 166
 - *Accept Call* [operation or activity] – waits for an operation or activity to be called.
 - *Reply Call* [operation or activity] – follows an Accept Call action, and responds to an operation or activity.
 - *Generate Event* [event] – generates an event. Can be used to raise an exception.
 - *Accept Event* [event] – waits for an event to occur.
 - *Create Object* [classifier] – creates a new instance of a classifier
 - *Destroy Object* [classifier] – destroys an instance of a classifier
 - *Read Attribute* [classifier attribute] – reads an attribute value from a classifier instance
 - *Write Attribute* [classifier attribute] – writes an attribute value to a classifier instance

- *Read Variable* [variable] – writes a value to a local variable. The variable can be used to store an output pin provided by an action to reuse later in the diagram. See *Example: Reading and writing variables* on page 169.
 - *Write Variable* [variable] - reads a value from a local variable. See *Example: Reading and writing variables* on page 169.
 - *Evaluate Expression* [expression text] – evaluates an expression and returns the value as an output pin.
 - *Unmarshall*[no object] – breaks an input object instance into several outputs computed from it.
 - *Region* [no object] – a composite activity that isolates a part of the graph. Equivalent to the UML Interruptible Activity Region.
 - *For Each* [no object] – loops an input collection to execute a set of actions specified into the decomposed activity. Equivalent to the UML Expansion Region.
 - *Loop Node* [expression text] – expression text
3. If the action type requires an action object, an additional field will be displayed directly below the Action Type list, allowing you to specify an activity, classifier, attribute, event, expression, operation, or variable upon which the action acts. You can use the tools to the right of the list to create an object, browse the available objects or view the properties of the currently selected object.
 4. Click OK to save your changes and return to the diagram.

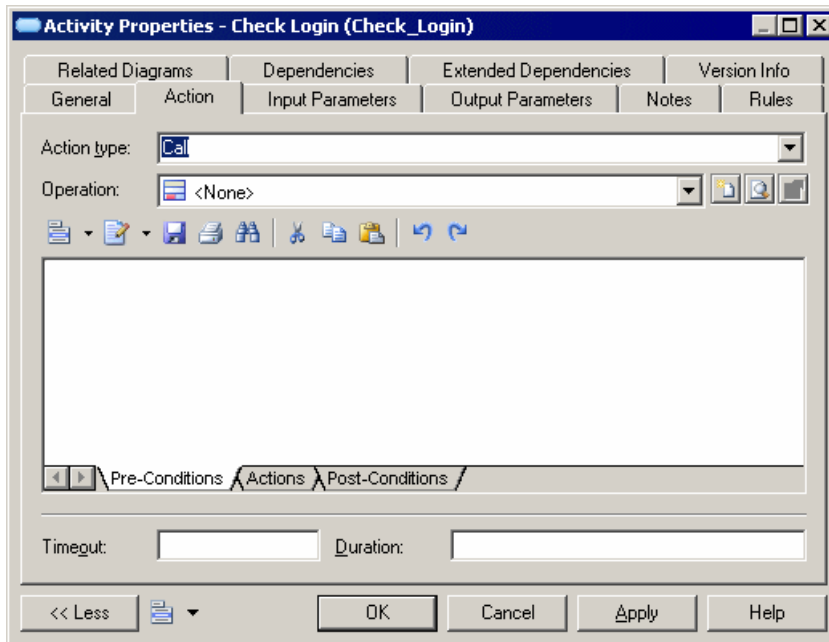

Example: Using the Call Action Type

One of the most common action types is Call, which allows an activity to invoke a classifier operation (or another activity).

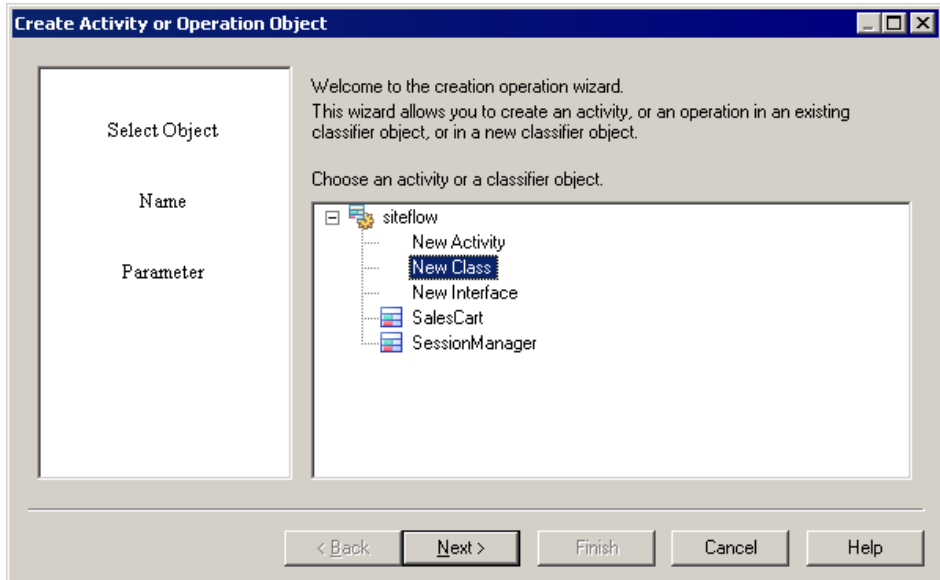

1. Create an activity and call it Check Login.

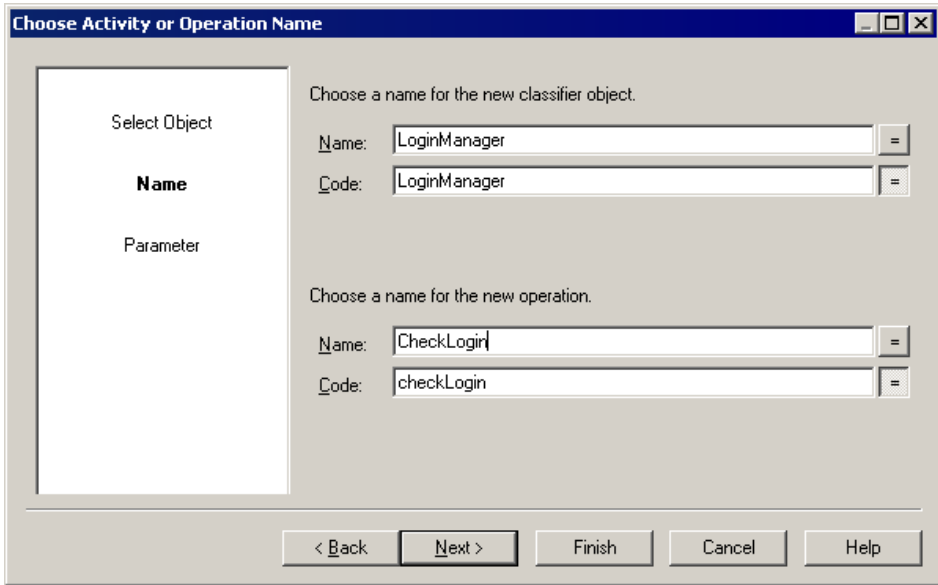

2. Open its property sheet, click the Action tab, and select Call from the Action type list. The Operation field appears:

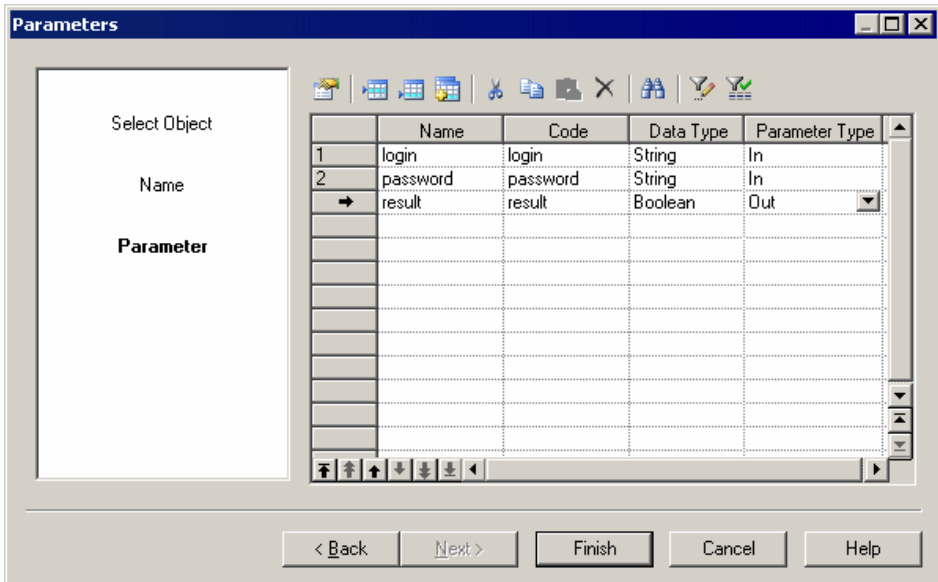

3. Click the Create tool to the right of the new field to open a wizard to choose an operation:

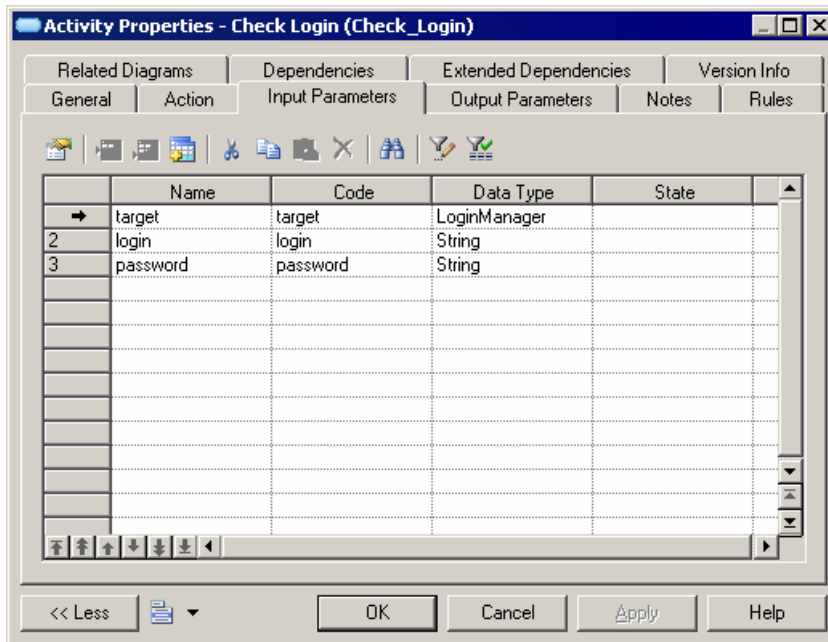

4. You can choose an existing classifier or activity, or select to create one. Select New Class, and then click Next:

5. Specify a name for the class and for the operation that you want to create, and then click Next:

6. Create two input and one output parameter for the operation, and then click Finish. The property sheet of the new operation opens to allow you to further specify the operation. When you are finished, click OK to return to the Activity property sheet and click the Input Parameters tab to view the parameters you have created:

Note that, in addition to the two input parameters, PowerDesigner has created a third, called "target", with the type of the new class.

7. Click Ok to save the changes and return to the diagram:

The activity now displays its two input and one output parameter (the target parameter is hidden by default). The class and operation that you have created are available in the Browser for further use.

Example: Reading and Writing Variables

Variables hold temporary values that can be passed between activities. You can create and access variables using the Write Variable and Read Variables action types

Variable Properties

Variables can have the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.

Property	Description
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Data type	Specifies the data type of the variable. You can choose a standard data type or specify a classifier. You can use the tools to the right of the list to create a classifier, browse the available classifiers or view the properties of the currently selected classifier.
Multiplicity	<p>Specifies the number of instances of the variable. If the multiplicity is a range of values, it means that the number of variables can vary at run time.</p> <p>You can choose between:</p> <ul style="list-style-type: none"> • * – none to unlimited • 0..* – zero to unlimited • 0..1 – zero or one • 1..* – one to unlimited • 1..1 – exactly one

Creating a Variable

To create a variable:

1. Open the property sheet of an activity and click the Action tab.
2. Select an action type of Write Variable, and then click the Create tool to the right of the variable field to create a new variable and open its property sheet.
3. Specify the name and other properties of the variable and click OK to return to the activity property sheet.

Writing to an Existing Variable

To write to an existing variable:

1. Open the property sheet of an activity and click the Action tab.
2. Select an action type of Write Variable, and then click the Select Object tool to the right of the variable field to choose the variable.
3. Select the appropriate variable in the list and click OK to return to the activity property sheet.

Reading from a Variable:

To read from a variable:

1. Open the property sheet of an activity and click the Action tab.
2. Select an action type of Read Variable, and then click the Create or Select Object tool to the right of the variable field to create a new variable or select an existing one.

Decomposed Activities and Sub-Activities

A decomposed activity is an activity that contains sub-activities. It is equivalent to a SubactivityState and an activity graph in UML. The decomposed activity behaves like a specialized package or container. A sub-activity can itself be decomposed into further sub-activities, and so on.

Note: To display all activities in the model in the List of Activities, including those belonging to decomposed activities, click the Include Composite Activities tool.

You can decompose activities either directly in the diagram using an editable composite view or by using sub-diagrams. Sub-objects created in either mode can be displayed in both modes, but the two modes are not automatically synchronized. **Editable** composite view allows you to quickly decompose activities and show direct links between activities and subactivities, while **Read-only (Sub-Diagram)** mode favors a more formal decomposition and may be more appropriate if you decompose through many levels.

You can choose the mode for viewing composite activities on a per-object basis, by right-clicking the symbol and selecting the desired mode from the **Composite View** menu.

You cannot create a package or any other UML diagram type in a decomposed activity, but you can use shortcuts to packages.

Working in Editable Composite View Mode

You can decompose an activity and create sub-activities within it simply by creating or dragging another activity onto its symbol. You can resize the parent symbol as necessary and create any number of sub-activities inside it. You can decompose a sub-activity by creating or dragging another activity onto its symbol, and so on.

Flows can link activities at the same level, or can link activities in the parent diagram with sub-activities in the Live Composite View:

Converting an Atomic Activity to a Decomposed Activity

You can convert an atomic activity to a decomposed activity in any of the following ways:

- Press CTRL and double-click the activity symbol (this will open the sub-activity directly)
- Open the property sheet of the activity and, on the General tab, select the Decomposed Activity radio button
- Right-click the activity and select Decompose Activity from the contextual menu

When you create a decomposed activity, a sub-activity diagram, which is empty at first, is added below its entry in the browser:

To open a sub-activity diagram, press CTRL and double-click on the decomposed activity symbol, or double-click the appropriate diagram entry in the Browser.

You can add objects to a sub-activity diagram in the same way as you add them to an activity diagram. Any activities that you add to a sub-activity diagram will be a part of its parent decomposed activity and will be listed under the decomposed activity in the Browser.

You can create several sub-activity diagrams within a decomposed activity, but we recommend that you only create one unless you want to design exception cases, such as error management.

Note: You can locate any object or any diagram in the Browser tree view from the current diagram window. To do so, right-click the object symbol, or the diagram background and select **Edit > Find in Browser**.

Converting an Activity Diagram to a Decomposed Activity

You can convert an activity diagram to a decomposed activity using the Convert Diagram to Activity wizard. The conversion option is only available once objects have been created in the diagram. By converting a diagram to a decomposed activity, you can then use the decomposed activity in another activity diagram.

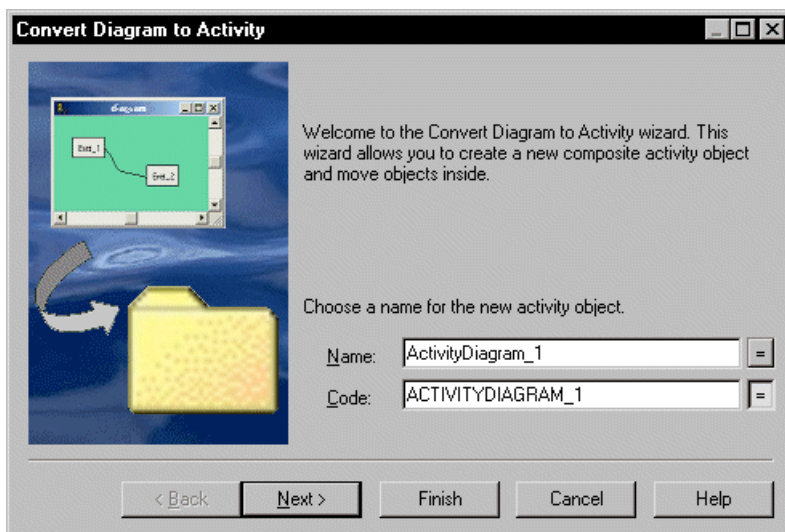

1. Right-click the diagram node in the Browser and select **Convert to Composite Activity** from the contextual menu.

or

Right-click the diagram background and select **Diagram > Convert to Composite Activity** from the contextual menu.

or

Select **Tools > Convert to Composite Activity**.

2. Specify a name and a code in the Convert Diagram to Activity page, and then click **Next** to open the **Selecting Objects to Move** page.
3. Select the activities that you want to move to the new decomposed activity diagram. Activities that you select will be moved in the Browser to under the new decomposed activity. Those that you do not select will remain in their present positions in the Browser and will be represented in the new sub-activity diagram as shortcuts.

4. Click Finish to exit the wizard. The new decomposed activity and its sub-activity diagram will be created, and any objects selected to be moved will now appear beneath the decomposed object in the Browser

Organization Units (OOM)

An *organization unit* can represent a company, a system, a service, an organization, a user or a role, which is responsible for an activity. In UML, an organization unit is called a swimlane, while in the OOM, "swimlane" refers to the symbol of the organization unit.

Note: To enable the display of organization unit swimlanes, select **Tools > Display Preferences**, and select the **Organization unit swimlane** checkbox on the **General** page, or right-click in the diagram background and select **Enable Swimlane Mode**.

An organization unit can be created in an activity diagram and can contain any of the other activity diagram objects:

Creating an Organization Unit

Create an organization unit to show the participant responsible for the execution of activities .

In order to add Organization Unit Swimlanes to your diagrams, you must select **Tools > Display Preferences** and select the **Organization Unit Swimlanes** checkbox.

- Use the Organization Unit Swimlane tool in the diagram Palette.
- Select **Model > Organization Units** to access the List of Organization Units, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Organization Unit**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Creating Organization Units with the Swimlane Tool

Use the Organization Unit Swimlane tool in the Palette to quickly create organization unit swimlanes.

Click in or next to an existing swimlane or pool of swimlanes to add a swimlane to the pool.

Click away from existing swimlanes to create a new pool.

Organization Unit Properties

You can modify an object's properties from its property sheet. To open an organization unit property sheet, double-click its swimlane symbol header or its Browser entry in the Organization Units folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Specifies a descriptive comment for the object.
Stereotype	<p>Extends the semantics of an object derived from existing objects but specific to your needs. You can type stereotypes directly in this field, or add stereotypes to the list by specifying them in your model's resource file or in an extended model definition. An organization unit has the following pre-defined stereotypes:</p> <ul style="list-style-type: none"> • Role – specifies a role a user plays • User • Group – specifies a group of users • Company • Organization – specifies an organization as a whole • Division – specifies a division in a global structure • Service – specifies a service in a global structure

Property	Description
Parent organization	<p>Specifies another organization unit as the parent to this one.</p> <p>For example, you may want to describe an organizational hierarchy between a department Dpt1 and a department manager DptMgr1 with DptMgr1 as the parent organization of Dpt1.</p> <p>The relationship between parent and child organization units can be used to group swimlanes having the same parent. For more information, see <i>Grouping and Ungrouping Swimlanes</i> on page 178 .</p>

Attaching Activities to Organization Units

Attach activities to organization units to graphically assign responsibility for them. When activities are attached to an organization unit displayed in a swimlane, the organization unit name is displayed in the Organization Unit list of their property sheets.

You attach activities to an organization unit by creating them in (or moving existing ones into) the required swimlane. Alternately, you can select an organization unit name from the Organization Unit list of the activity property sheet, and click OK to attach it.

To detach activities from an organization unit, drag them outside the swimlane or select <None> in the activity property sheet.

Displaying a Committee Activity

A committee activity is a decomposed activity whose sub-activities are managed by several organization units.

1. Open the property sheet of a decomposed activity.
2. Select **Committee Activity** from the Organization Unit list and click **OK**.

This value is only available for decomposed activities.

3. In the diagram, resize the decomposed activity symbol to cover all the appropriate swimlanes.

The symbol background color changes on the swimlanes depending on whether each is responsible for sub-activities.

In the following example, all sub-activities of Payment are managed in the Accountancy organization unit:

The symbol background of the committee activity is lighter and hatched on Sales and Delivery since they do not:

- Manage any sub-activities
- Have any symbol in the sub-activity diagram

Note that this display does not appear in composite view mode.

Managing Swimlanes and Pools

Each group of one or more swimlanes forms a pool. You can create multiple pools in a diagram, and each pool is generally used to represent a separate organization.

To select an individual swimlane in a pool, click its header:

To select a pool, click any of its swimlanes or position the cursor above the pool, until you see a vertical arrow pointing to the frame, then click to display the selection frame:

Moving, Copying and Pasting Swimlanes

You can move, copy, and paste swimlanes and pools in the same or in another diagram.

Diagram	What happens...
Same	When you move a swimlane or pool within the same diagram, all symbols inside the swimlane(s) are moved at the same time (even if some elements are not formally attached), so as to preserve the layout of the diagram.
Different	When you move or copy a swimlane or pool to another folder or diagram, the symbols inside the swimlane(s) are not copied.

If a swimlane is dropped on or near another swimlane or pool, it joins the pool.

In the following example, Sales forms a pool with Accountancy and Delivery, and is moved to another pool containing Customer and Customer Service:

After the move, Sales has moved from its original pool, and joined the pool containing Customer and Customer Service:

If the moved swimlane is dropped away from another swimlane or pool, it forms a new pool by itself, as in the following example:

If you move linked objects inside a swimlane, the width or height of the swimlane varies with them.

Note: The auto-layout function is unavailable with organization units displayed as swimlanes.

Grouping and Ungrouping Swimlanes

Group organization unit swimlanes within a pool to organize them under a common parent or user-defined name.

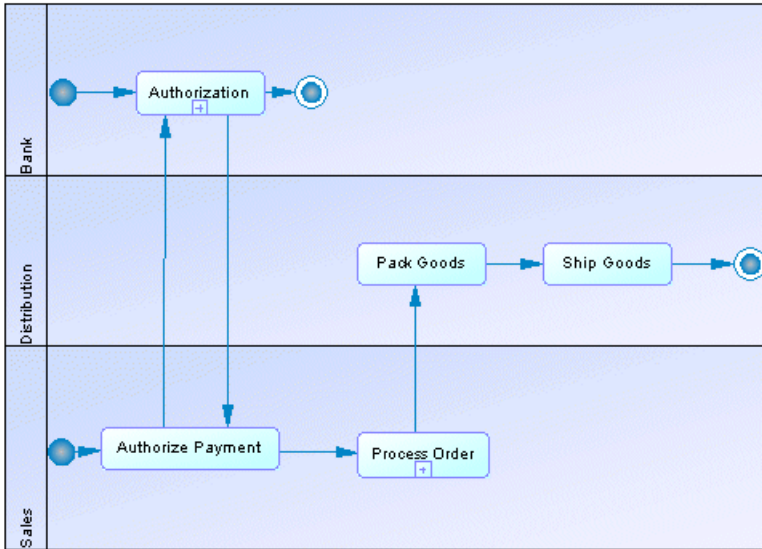

To group swimlanes within a pool, right-click the pool, select **Swimlane Group Type**, and then select one of the following options:

- **By Parent** - to assign the name of the last common parent for the group. This name comes from the Parent Organization Unit field in the swimlanes property sheet.

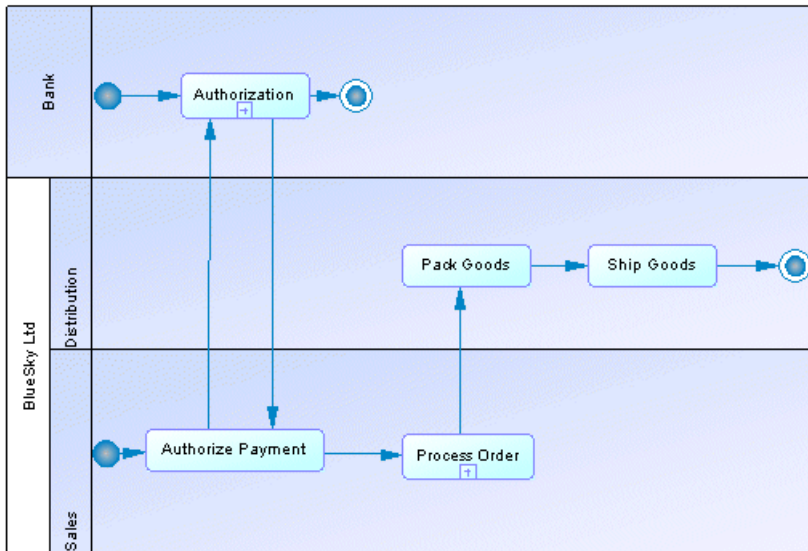

- **User-Defined** - to assign a name of your choice for the group. Then, you must select at least two attached swimlanes, and select **Symbol > Group Symbols** from the menu bar to display a default name that you can modify.

To ungroup swimlanes, select **Ungroup Symbols** from the pool contextual menu or **Select Symbol > Ungroup Symbols**.

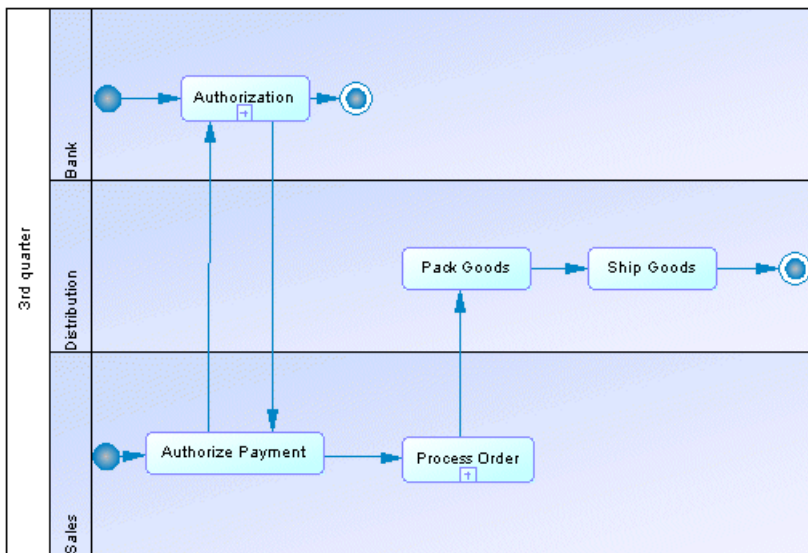

The following example shows a pool without any group:

In the following example, Sales and Distribution are grouped by their BlueSky Ltd common parent:

In the following example, the pool is assigned a user-defined group named 3rd quarter:

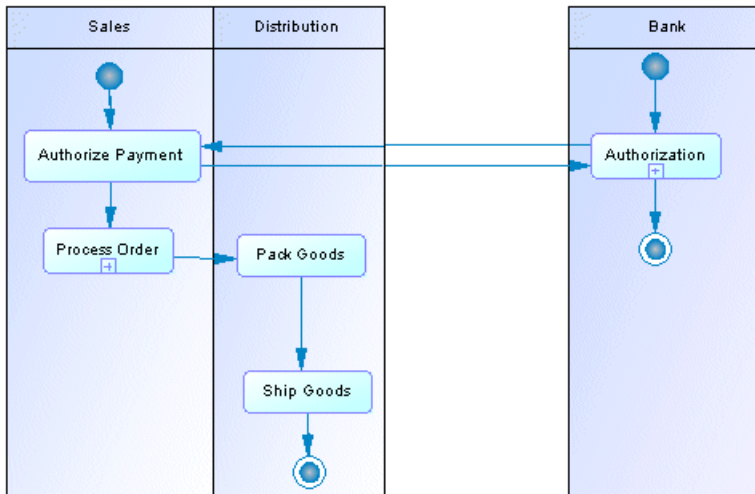

Creating Links Between Pools of Swimlanes

Create links between pools or between activities in separated pools to represent interactions between them.

To create links between pools of swimlanes, simply click the **Flow** tool in the Palette and drag a flow from one activity in a pool to another in a different pool or from one pool to another.

In the following example, flows pass between Authorize Payment in the Sales swimlane in one pool and Authorization in the Bank swimlane in another pool:

Note: Such links between activities in separate pools are not visible when the swimlanes are not in composite view mode.

Changing the Orientation of Swimlanes

You can change the orientation of swimlanes so that they run vertically (from top to bottom) or horizontally (from left to right). All swimlanes in a diagram must have the same orientation.

1. Select **Tools > Display Preferences** to open the Display Preferences dialog box.
2. Select the appropriate radio button in the Organization unit swimlane groupbox, and click **OK**.

Resizing Swimlanes

You can resize swimlanes within a pool by clicking the dividing line between them and dragging it.

When you change the width or height of an individual swimlane, all activity symbols attached to the swimlane keep their position.

You can resize a pool by selecting one of the handles around the pool, and dragging it into any direction. Any other pools your diagram may contain may also be resized to preserve the diagram layout.

Changing the Format of a Swimlane

You can change the format of swimlanes or a pool using the Symbol Format dialog box. Format changes apply to all swimlanes in the pool.

1. Right-click the swimlane or a pool, and select **Format** to display the Symbol Format dialog box.
2. Enter or select changes in the different tabs, and click **OK** to return to the diagram.

Starts (OOM)

A *start* is a starting point of the flow represented in the diagram.

A start can be created in the following diagrams:

- Activity Diagram - one or more per diagram

- Statechart Diagram - one or more per diagram
- Interaction Overview Diagram - one only per diagram

You should not use the same start in two diagrams, and you cannot create shortcuts of starts.

Note: The start is compared and merged in the Merge Model feature, which checks that there is no additional start in decomposed activities.

Creating a Start

You can create a start in any of the following ways:

- Use the Start tool in the diagram Palette
- Select **Model > Starts** to access the List of Starts, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Start**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Start Properties

You can modify an object's properties from its property sheet. To open a start property sheet, double-click its diagram symbol or its Browser entry in the Starts folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Specifies a descriptive comment for the object.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs. You can type stereotypes directly in this field, or add stereotypes to the list by specifying them in your model's resource file or in an extended model definition.

Ends (OOM)

An *end* is a termination point of the flow represented in the diagram.

An end can be created in the following diagrams:

- Activity Diagram
- Statechart Diagram
- Activity Overview Diagram

You can create several ends within the same diagram, if you want to show divergent end cases, like errors scenarios:

If there is no end, the diagram contains an endless activity. However, a decomposed activity must always contain at least one end.

You should not use the same end in more than one diagram. You are not allowed to use shortcuts of ends, but graphical synonyms are permitted.

Creating an End

You can create an end in any of the following ways:

- Use the End tool in the diagram Palette
- Select **Model > Ends** to access the List of Ends, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > End**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

End Properties

You can modify an object's properties from its property sheet. To open an end property sheet, double-click its diagram symbol or its Browser entry in the Ends folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Specifies a descriptive comment for the object.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs. You can type stereotypes directly in this field, or add stereotypes to the list by specifying them in your model's resource file or in an extended model definition.

Property	Description
Termination	Specifies whether the end is the termination of the entire activity or simply one possible flow.

Decisions (OOM)

A *decision* specifies which path to take, when several paths are possible.

A decision can be created in the following diagrams:

- Activity Diagram
- Interaction Overview Diagram

A decision can have one or more input flows and one or more output flows, each labeled with a distinct *guard condition*, a condition that must be satisfied for an associated flow to execute some action. Your guard conditions should avoid ambiguity by not overlapping, yet should also cover all possibilities in order to avoid process freeze.

A decision can represent:

- A conditional branch: one input flow and several output flows. In the following example, the control flow passes to the left if the age given in the application form is <18, to the right if the age is >65, and takes the another route if the age is not mentioned:

You can display a condition on the decision symbol in order to factorize the conditions attached to the flows. In the following example, the condition $Total * NB + VAT > 10.000$ is entered in the Condition tab in the decision property sheet, and True and False are entered in the Condition tabs of the flows:

- A merge: several input flows and one output flow. In the following example, the Subscription and Charge account flows merge to become the Ship order flow:

A decision allows you to create complex flows, such as:

- if ... then ... else ...
- switch ... case ...
- do ... while ...
- loop
- for ... next ...

Note: It is not possible to attach two flows of opposite directions to the same corner on a decision symbol.

Creating a Decision

You can create a decision in any of the following ways:

- Use the Decision tool in the diagram Palette
- Select **Model > Decisions** to access the List of Decisions, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Decision**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Decision Properties

You can modify an object's properties from its property sheet. To open a decision property sheet, double-click its diagram symbol or its Browser entry in the Decisions folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs. You can type stereotypes directly in this field, or add stereotypes to the list by specifying them in your model's resource file or in an extended model definition.
Type	Calculated read-only value showing the type of the decision that can have the following values: <ul style="list-style-type: none"> • Incomplete - No input or no output transition has been defined or exactly one input and one output transitions have been defined • Conditional branch – One input and several outputs have been defined • Merge - Several inputs and one output have been defined

Decision Property Sheet Condition Tab

The Condition tab contains the following properties:

Properties	Description
Alias	Specifies a short name for the condition, to be displayed next to its symbol in the diagram.
Condition (text box)	Specifies a condition to be evaluated to determine how the decision should be traversed. You can enter any appropriate information in this box, as well as open, insert and save text files. You can open the Condition tab by right-clicking the decision symbol, and selecting Condition in the contextual menu.

Synchronizations (OOM)

A *synchronization* enables the splitting or synchronization of control between two or more concurrent actions.

A synchronization can be created in the following diagrams:

- Activity Diagram
- Statechart Diagram

- Interaction Overview Diagram

Synchronizations are represented as horizontal or vertical lines. You can change the orientation of the symbol by right-clicking it and selecting Change to Vertical or Change to Horizontal from the contextual menu.

A synchronization can be either a:

- Fork - Splits a single input flow into several independent output flows executed in parallel:

- Join – Merges multiple input flows into a single output flow. All input flows must reach the join before the single output flow continues:

In the following example, the flow coming into the first synchronization is split into two separate flows, which pass through Check Customer Account and Check Stock. Then both flows are merged into a second synchronization giving a single flow, which leads to Process Order:

Creating a Synchronization

You can create a synchronization in any of the following ways:

- Use the Synchronization tool in the diagram Palette
- Select **Model > Synchronizations** to access the List of Synchronizations, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Synchronization**

By default, the synchronization symbol is created horizontally. To toggle between horizontal and vertical display, right-click the symbol and select Change to Vertical or Change to Horizontal in the contextual menu.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Synchronization Properties

You can modify an object's properties from its property sheet. To open a synchronization property sheet, double-click its diagram symbol or its Browser entry in the Synchronizations folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Specifies a descriptive comment for the object.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs. You can type stereotypes directly in this field, or add stereotypes to the list by specifying them in your model's resource file or in an extended model definition.
Timeout	Defines a timeout limit for waiting until all transitions end. It is empty when the value = 0.
Type	[read-only] Calculates the form of the synchronization <ul style="list-style-type: none"> • Incomplete - No or exactly one input or no output transition has been defined • Conditional branch – One input and several outputs have been defined • Merge - Several inputs and one output have been defined

Flows (OOM)

A *flow* is a route the control flow takes between objects . The routing of the control flow is made using guard conditions defined on flows. If the condition is true, the control is passed to the next object.

A flow can be created in the following diagrams:

- Activity Diagram
- Interaction Overview Diagram

A flow between an activity and an object node indicates that the execution of the activity puts an object in a specific state. When a specific event occurs or when specific conditions are satisfied, the control flow passes from the activity to the object node. A flow from an object

node to an activity means that the activity uses this specific state in its execution. In both cases, the flow is represented as a simple arrow.

In the following example the flow links Process Order to Ship US Postal Ground:

A flow can link shortcuts. A flow accepts shortcuts on both extremities to prevent it from being automatically moved when a process is to be moved. In this case, the process is moved and leaves a shortcut, but contrary to the other links, the flow is not moved. Shortcuts of flows do not exist, and flows remain in place in all cases.

The following rules apply:

- *Reflexive flows* (same source and destination process) are allowed on processes.
- Two flows between the same source and destination objects are permitted, and called *parallel flows*.

Note: When flows are compared and merged by the Merge Model feature, they are matched by trigger event first, and then by their calculated name. When two flows match, the trigger actions automatically match because there cannot be more than one trigger action.

Creating a Flow

You can create a flow in any of the following ways:

- Use the Flow/Resource Flow tool in the diagram Palette
- Select **Model > Flows** to access the List of Flows, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Flow**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Flow Properties

You can modify an object's properties from its property sheet. To open a flow property sheet, double-click its diagram symbol or its Browser entry in the Flows folder.

The General tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.

Property	Description
Comment	Specifies a descriptive comment for the object.
Source	Specifies the object that the flow leads from. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object. You can also open the property sheet of the source object by clicking the Source button located at the top part of the current object property sheet.
Destination	Specifies the object that the flow leads to. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object. You can also open the property sheet of the destination object by clicking the Destination button located at the top part of the current object property sheet.
Stereotype	Extends the semantics of an object derived from existing objects but specific to your needs. You can type stereotypes directly in this field, or add stereotypes to the list by specifying them in your model's resource file or in an extended model definition.
Flow type	Specifies the type of the flow. You can create your own type of flow in the list, or choose one of the following values: <ul style="list-style-type: none"> • Success - defines a successful flow • Timeout - defines the occurrence of a timeout limit • Technical error • Business error • Compensation - defines a compensation flow <p>The flow type is unavailable if you associate an event with the flow on the Condition tab.</p>
Weight	Specifies the number of objects consumed on each traversal.

Note: You can view input and output flows of a process from its property sheet by clicking the Input Flows and Output Flows sub-tabs of the Dependencies tab.

Flow Property Sheet Condition Tab

Parameter	Description
Alias	Short name for the condition, to be displayed next to its symbol in the diagram.

Parameter	Description
Condition (text box)	Specifies a condition to be evaluated to determine how the flow should be traversed. You can enter any appropriate information in this box, as well as open, insert and save text files. You can open the Condition tab by right-clicking the flow symbol, and selecting Condition in the contextual menu.

Flow Property Sheet Parameters Tab

The Parameters tab lists the parameters that are passed along the flow. The list is automatically completed if you draw the flow between two activity parameters .

Flow Property Sheet Transformation Tab

The Transformations tab specifies a data transformation to apply to input tokens. For example, it could extract a single attribute value from an input object.

Object Nodes (OOM)

An *object node* is the association of an object (instance of a class) and a state. It represents an object in a particular state.

Its symbol is a rectangle as shown below:

An object node can be created in the following diagrams:

- Activity Diagram

The same object can evolve after several actions defined by activities, have been executed. For example, a document can evolve from the state initial, to draft, to reviewed, and finally turn into a state approved.

You can draw flows from an activity to an object node and inversely:

- A flow from an activity to an object node - means that the execution of the activity puts the object in a specific state. It represents the result of an activity
- A flow from an object node to an activity - means that the activity uses this specific state in its execution. It represents a data flow between them

When an activity puts an object in a state and this object is immediately reused by another activity, it shows a transition between two activities with some data exchange, the object node representing the data exchange.

For example, the object nodes Order approved and Invoice edited, are linked to the classes Order and Invoice, which are represented in a separate class diagram:

Creating an Object Node

You can create an object node in any of the following ways:

- Use the Object Node tool in the diagram Palette
- Select **Model > Object Nodes** to access the List of Object Nodes, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Object Node**
- Drag and drop a classifier from the Browser onto an activity diagram. The new object node will be linked to and display the name of the classifier.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Object Node Properties

You can modify an object's properties from its property sheet. To open an object node property sheet, double-click its diagram symbol or its Browser entry in the Object Nodes folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Data type	Specifies the data type of the object node. You can use the tools to the right of the list to create a classifier, browse the complete tree of available classifiers or view the properties of the currently selected classifier.
State	Specifies the state of the object node. You can type the name of a state here or, if a classifier has been specified as the data type, select one of its states from the list. You can use the tools to the right of the list to create a state, browse the complete tree of available states or view the properties of the currently selected state.

States (OOM)

A *state* represents a situation during the life of a classifier that is usually specified by conditions. It can also be defined as the situation of a classifier waiting for events. Stability and duration are two characteristics of a state.

A state can be created in the following diagrams:

- Statechart Diagram

A state can be atomic or decomposed:

- An atomic state does not contain sub-states, and has the following symbol:

- A decomposed state contains sub-states, which are represented in a sub-diagram, and has the following symbol:

For more information on decomposed states, see *Decomposed states and sub-states* on page 196.

Several states in a statechart diagram correspond to several situations during the life of the classifier.

Events and condition guards on output transitions define the stability of a state. Some actions can be associated with a state, especially when the object enters or exit the state. Some actions can also be performed when events occur inside the state; those actions are called internal transitions, they do not cause a change of state.

You cannot decompose shortcuts of states.

Drag a Class, Use Case or Component in a Statechart Diagram

The statechart diagram describes the behavior of a classifier. To highlight the relationship between a classifier and a state, you can define the context classifier of a state using the Classifier list in the state property sheet. This links the state to a use case, a component or a class.

You can also move, copy and paste, or drag a class, use case or component and drop it into a statechart diagram to automatically create a state associated with the element that has been moved.

Creating a State

You can create a state in any of the following ways:

- Use the State tool in the diagram Palette
- Select **Model > States** to access the List of States, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > State**
- Drag and drop a class, use case or component into the diagram

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

State Properties

You can modify an object's properties from its property sheet. To open a state property sheet, double-click its diagram symbol or its Browser entry in the States folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for states.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Classifier	Classifier linked to the state. It can be a use case, a class or a component. When a classifier is selected, it is displayed in between brackets after the state name in the Browser. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object
Composite status	If you select the Decomposed state option, the state becomes a decomposed state. If you select the Atomic state option, the state becomes an atomic state, and all its child objects are deleted

State Property Sheet Actions Tab

You can specify a set of internal actions on an atomic or decomposed state from the Actions tab in the state property sheet. They represent actions performed within the scope of the state when some events occur. You can create and define the properties of the action from the Actions tab, or double-click the arrow at the beginning of a line to display the action property sheet.

Note: You can open the Actions tab by right clicking the state symbol in the diagram, and selecting Actions from the contextual menu.

For more information on actions, see *Actions (OOM)* on page 204.

State Property Sheet Deferred Events Tab

The Deferred Events tab contains an Add Objects tool that allows you to add already existing events but not to create new events. This list is similar to the list of Business Rules that only reuse elements and does not create them.

The difference between an event and a *deferred event* is that an event is always instantaneous and dynamically handled by a state, whereas a deferred event is an event that occurs during a particular state in the object life cycle but it is not directly used up by the state.

A deferred event occurs in a specific state, is then handled in a queue, and is triggered by another state of the same classifier later.

State Property Sheet Sub-States Tab

The Sub-States tab is displayed when the current state is decomposed in order to display a list of child states. You can use the Add a row and Delete tools to modify the list of child states.

The Sub-States tab disappears when you turn the current state to atomic because this action deletes the children of the state.

Decomposed States and Sub-states

A decomposed state is a state that contains sub-states. The decomposed state behaves like a specialized package or container. A sub-state can itself be decomposed into further sub-states, and so on.

Note: To display all states in the model in the List of States, including those belonging to decomposed states, click the Include Composite States tool.

You can decompose states either directly in the diagram using an editable composite view or by using sub-diagrams. Sub-objects created in either mode can be displayed in both modes, but the two modes are not automatically synchronized. **Editable** composite view allows you to quickly decompose states and show direct links between states and substates, while **Read-only (Sub-Diagram)** mode favors a more formal decomposition and may be more appropriate if you decompose through many levels.

You can choose how to view composite states on a per-object basis, by right-clicking the symbol and selecting the desired mode from the **Composite View** menu.

You cannot create a package or any other UML diagram type in a decomposed state, but you can use shortcuts to packages.

Working in Editable Composite View Mode

You can decompose a state and create substates within it simply by creating or dragging another state onto its symbol. You can resize the parent symbol as necessary and create any

number of substates inside it. You can decompose a substate by creating or dragging another state onto its symbol, and so on.

Transitions can link states at the same level, or can link states in the parent diagram with substates in the Editable Composite View mode:

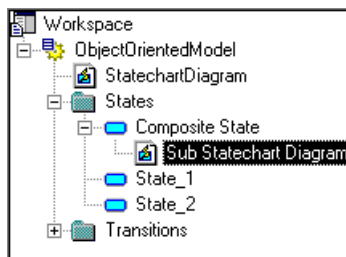

Working with Sub-State Diagrams

You can convert an atomic state to a decomposed state in any of the following ways:

- Press CTRL and double-click the state symbol (this will open the sub-state directly)
- Open the property sheet of the state and, on the General tab, select the Decomposed State radio button
- Right-click the state and select Decompose State

When you create a decomposed state, a sub-state diagram, which is empty at first, is added below its entry in the browser:

To open a sub-state diagram, press CTRL and double-click on the decomposed state symbol, or double-click the appropriate diagram entry in the Browser.

You can add objects to a sub-state diagram in the same way as you add them to an state diagram. Any states that you add to a sub-state diagram will be a part of its parent decomposed state and will be listed under the decomposed state in the Browser.

You can create several sub-state diagrams within a decomposed state, but we recommend that you only create one unless you want to design exception cases, such as error management.

Note: You can locate any object or any diagram in the Browser tree view from the current diagram window. To do so, right-click the object symbol, or the diagram background and select **Edit > Find in Browser**.

Converting a Statechart Diagram to a Decomposed State

You can convert a statechart diagram to a decomposed state using the Convert Diagram to State wizard. The conversion option is only available once objects have been created in the diagram. By converting a diagram to a decomposed state, you can then use the decomposed state in another statechart diagram.

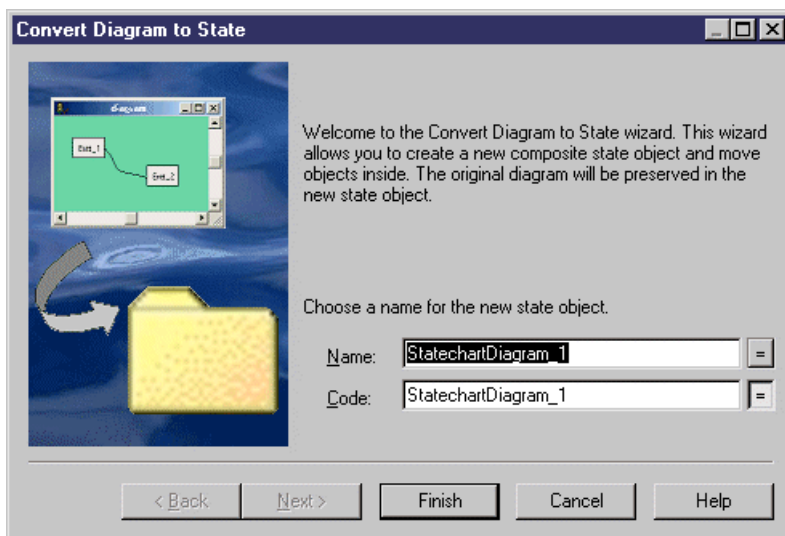

1. Right-click the diagram node in the Browser and select Convert to Decomposed State from the contextual menu.

or

Right-click the diagram background and select **Diagram > Convert to Decomposed State** from the contextual menu.

or

Select **Tools > Convert to Decomposed State**.

2. Specify a name and a code in the Convert Diagram to State page, and then click Next to open the Selecting Objects to Move page.
3. Select the states that you want to move to the new decomposed state diagram. States that you select will be moved in the Browser to under the new decomposed state. Those that you do not select will remain in their present positions in the Browser and will be represented in the new sub-state diagram as shortcuts.

- Click Finish to exit the wizard. The new decomposed state and its sub-state diagram will be created, and any objects selected to be moved will now appear beneath the decomposed object in the Browser

Transitions (OOM)

A *transition* is an oriented link between states, which indicates that an element in one state can enter another state when an event occurs (and, optionally, if a guard condition is satisfied). The expression commonly used in this case is that a transition is fired.

A transition can be created in the following diagrams:

- Statechart Diagram

The statechart diagram transition is quite similar to the flow in the activity diagram, with the addition of a few properties:

- A trigger event: it is the event that triggers the transition (when you copy a transition, the trigger event is also copied)
- A trigger action: it specifies the action to execute when the transition is triggered

The activity diagram is a simplification of the statechart diagram in which the states have only one action and the transition has a triggered event corresponding to the end of the action.

The transition link is represented as a simple arrow. The associated event, the condition and the action to execute are displayed above the symbol.

The following rules apply:

- Reflexive transitions* only exist on states
- A trigger event can only be defined if the source is a start or a state
- Two transitions can not be defined between the same source and destination objects (*parallel transitions*). The Merge Model feature forbids this.

Note: When transitions are compared and merged by the Merge Model feature, they are matched by trigger event first, and then by their calculated name. When two transitions match, the trigger actions automatically match because there cannot be more than one trigger action.

Creating a Transition

You can create a transition in any of the following ways:

- Use the Transition tool in the diagram Palette
- Select **Model > Transitions** to access the List of Transitions, and click the Add a Row tool

- Right-click the model or package in the Browser, and select **New > Transition**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Transition Properties

You can modify an object's properties from its property sheet. To open an transition property sheet, double-click its diagram symbol or its Browser entry in the Transitions folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users. Displays a read-only value named after both extremities of the transition.
Code	Specifies the technical name of the object, which is used for generating code or scripts. Displays a read-only value named after both extremities of the transition.
Comment	Descriptive comment for the object.
Source	Where the transition starts from. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object
Destination	Where the transition ends on. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object
Stereotype	Extends the semantics of the object beyond the core UML definition.
Flow type	Represents a condition that can be attached to the transition. You can choose between the following default types or create your own: <ul style="list-style-type: none"> • Success – Defines a successful flow • Timeout – Defines a timeout limit • Exception – Represents an exception case

Transition Property Sheet Condition Tab

The Condition tab contains the following properties:

Property	Description
Alias	Short name for the condition, to be displayed next to its symbol in the diagram.
Condition (text box)	Specifies a condition to be evaluated to determine whether the transition should be traversed. You can enter any appropriate information in this field, as well as open, insert and save text files.

Transition Property Sheet Trigger Tab

The Trigger tab contains the following properties:

Property	Description
Trigger event	Specifies the event (see <i>Events (OOM)</i> on page 201) that triggers the transition. You can click the Properties tool beside this box to display the event property sheet. It is available only for transitions coming from a state or a start and is not editable in other cases. When you define a trigger event, the inverse relationship is displayed in the Triggered Objects tab of the corresponding event property sheet. The Triggered Objects tab lists transitions that the event can trigger.
Event arguments	Specifies a comma-separated list of event arguments (arg1, arg2,...).
Trigger action	Specifies the action to execute when the transition is triggered.
Operation	Read-only list that lists operations of the classifier associated with the state that is the source of the transition. It allows you to specify the action implementation using an operation. It is grayed and empty when the classifier is not a class
Operation arguments	Arguments of an event defined on an operation

Events (OOM)

An *event* is the occurrence of something observable. The occurrence is assumed to be instantaneous and should not have duration.

An event can be created in the following diagrams:

- Statechart Diagram

Events convey information specified by parameters. They are used in the statechart diagram in association with transitions: they are attached to transitions to specify which event fires the transition. They are also used in association with actions: the event can trigger the change of state of a classifier or the execution of an internal action on a state.

The same event can be shared between several transitions and actions. It is reusable by nature because it is not dependent on the context.

The event icon in the Browser is the following symbol:

Predefined Events

You can select an event from the Trigger Event list in the action and transition property sheets. You can also select a predefined event value from the Trigger Event list if you define the event on an action.

The list of events contains the following predefined values:

- Entry: the action is executed when the state is entered
- Do: a set of actions is executed after the entry action
- Exit: the action is executed when the state is exited

Examples

An event could be:

- A boolean expression becoming true
- The reception of a signal
- The invocation of an operation
- A time event, like a timeout or a date reached

You can display the arguments of an event in the statechart diagram.

For more information on arguments of an event, see *Defining event arguments* on page 204.

Creating an Event

You can create an event in any of the following ways:

- Select **Model > Events** to access the List of Events, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Event**
- Double-click a transition to open its property sheet, click the Trigger tab, and then click the Create tool to the right of the Trigger event box

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Event Properties

You can modify an object's properties from its property sheet. To open an event, double-click its Browser entry in the Events folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.

Property	Description
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.

Event Property Sheet Dependencies Tab

The Dependencies tab contains a Triggered Objects tabbed tab that displays the actions on states and on transitions that are triggered by this event.

Event Property Sheet Parameters Tab

The Parameters tab lists all the parameters associated with the event. It allows you to define event parameters that correspond to the event signature.

You can add a parameter in the list by clicking the Add a Row tool, and then open its property sheet by clicking on the Properties tool. A parameter has the following properties:

Property	Description
Parent	Event to which the parameter belongs
Name	Name of the parameter
Code	Reference name of the parameter
Comment	Descriptive comment for the parameter
Data type	Set of instances sharing the same semantics
Array	When selected, indicates that the data type is a table format
Parameter Type	<p>Direction of information flow for the parameter. Indicates what is returned when the parameter is called by the event during the execution process. You can choose from the following:</p> <ul style="list-style-type: none"> • In – Input parameter passed by value. The final value can not be modified and information is not available to the caller • In/Out – Input parameter that may be modified. The final value may be modified to communicate information to the caller • Out – Output parameter. The final value may be modified to communicate information to the caller

Property	Description
Default value	<p>Default value when a parameter is omitted. For example:</p> <p>Use an operation <code>oper(string param1, integer param2)</code>, and specify two arguments <code>oper(val1, val2)</code> during invocation. Some languages, like C++, allow you to define a default value that is then memorized when the parameter is omitted during invocation.</p> <p>If the declaration of the method is <code>oper(string param1, integer param2 = default)</code>, then the invocation <code>oper(val1)</code> is similar to <code>oper(val1, default)</code>.</p>

Defining Event Arguments

Event arguments are slightly different from event parameters. Event arguments are defined on the action or on the transition that receives the event, they are dependent on the particular context that follows this receipt.

It is a text field defined on the action or the transition. You can edit it and separate arguments with a comma, for example: `arg1, arg2`. There is no control of coherence between event parameters and event arguments in PowerDesigner.

Example

An event can have a parameter "person" that is for example, a person sending a request. Within the context of a transition triggered by this event, you may clearly know that this parameter is a customer, and then purposefully call it "customer" instead of "person".

Actions (OOM)

An *action* is a specification of a computable statement. It occurs in a specific situation and may comprise predefined events (entry, do and exit) and internal transitions.

An action can be created in the following diagrams:

- Statechart Diagram

Internal transitions can be defined on a state, they are internal to the state and do not cause a change of state; they perform actions when triggered by events. Internal transitions should not be compared to reflexive transitions on the state because the entry and exit values are not executed when the internal event occurs.

An action contains a *Trigger Event* property containing the specification of the event that triggers the action.

For more information on events, see *Events (OOM)* on page 201.

Action on State and on Transition

In an OOM, an action is used in the statechart diagram in association with states: the action is executed in the state during entry or exit. It is also used in association with transitions: the action is executed when the transition is triggered.

In UML, the difference is that an action is displayed in interaction diagrams (in association with messages) and in statechart diagrams.

When you define an action on a state, you can define several actions without any limitation. When you define an action on a transition, there can only be *one* action as the transition can execute only one action. An action defined on a state can contain the event that triggers it: the action property sheet contains the event property sheet. An action defined on a transition does not contain the event that triggers it: you can only enter the action in a text field.

In the following figure, you can see actions defined on states, and actions defined on transitions together with the order of execution of actions:

The action icon in the Browser is a two-wheel symbol, it is defined within a state node but does not appear within a transition node.

Creating an Action

You can create an action in any of the following ways:

- Open the Actions tab in the property sheet of a state, and click the Add a Row tool
- Open the Trigger tab in the property sheet of a transition, and type the action name in the Trigger action box

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Action Properties

You can modify an object's properties from its property sheet. To open an action property sheet, double-click its diagram symbol or its Browser entry in the Actions folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Trigger event	<p>Specifies the role an action plays for a state or the event that triggers its execution. You can:</p> <ul style="list-style-type: none"> • Add an event to an action by choosing it from the list. • Add multiple events by clicking the ellipsis tool next to the list. • Create a new event by clicking the Create tool. • Select an event created in the current model or other models by clicking the Select Trigger Event tool. <p>Click the Properties tool to display the event property sheet. When a trigger event is defined on an action, the inverse relationship is displayed in the Triggered Objects sub-tab of the Dependencies tab of the event property sheet (see <i>Events (OOM)</i> on page 201).</p>
Event arguments	Arguments of an event defined on a state. Arguments are instances of parameters or names given to parameters in the context of executing an event. You can specify a list of event arguments (arg1, arg2,...) in this box
Operation	Read-only list that lists operations of the classifier associated with the state. It allows you to specify the action implementation using an operation. It is grayed and empty when the classifier is not a class
Operation arguments	Arguments of an event defined on an operation

Action Property Sheet Condition Tab

You can specify an additional condition on the execution of an action when the event specified by the trigger event occurs. The Condition tab is available for actions defined on states. It displays the following property:

Alias

The Alias allows you to edit or summarize a condition attached to an action. You can also use a text zone in which you detail the condition. For example, you can write information on the condition to execute, as well as open, insert and save any text files containing valuable information.

It is recommended that you write an alias (short expression) when you use a long condition so as to display the alias instead of the condition in the diagram.

The condition of an action is displayed between brackets:

Junction Points (OOM)

A *junction point* can merge and/or split several input and output transitions. It is similar to the decision in the activity diagram.

A junction point can be created in the following diagrams:

- Statechart Diagram

You are not allowed to use shortcuts of a junction point. A junction point may be dependent on event parameters if the parameters include some split or merge variables for example.

You can attach two transitions of opposite directions to the same junction point symbol.

The symbol of a junction point is an empty circle:

Creating a Junction Point

You can create a junction point in any of the following ways:

- Use the Junction Point tool in the diagram Palette
- Select **Model > Junction Points** to access the List of Junction Points, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Junction Point**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Junction Point Properties

You can modify an object's properties from its property sheet. To open a junction point property sheet, double-click its diagram symbol or its Browser entry in the Junction Points folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.

CHAPTER 5 Building Implementation Diagrams

The diagrams in this chapter allow you to model the physical environment of your system, and how its components will be deployed. PowerDesigner provides two types of diagrams for modeling your system in this way:

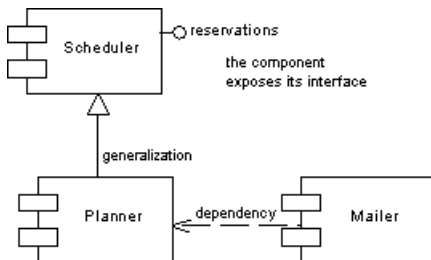

- A *component diagram* represents your system decomposed into self-contained components or sub-systems. It can show the classifiers that make up these systems together with the artifacts that implement them, and exposes the interfaces offered or required by each component, and the dependencies between them. For more information, see *Component Diagram Basics* on page 209.
- A *deployment diagram* allows you to represent the execution environment for a project. It describes the hardware on which each of your components will run and how that hardware is connected together. For more information, see *Deployment Diagram Basics* on page 211.

Component Diagram Basics

A *component diagram* is a UML diagram that provides a graphical view of the dependencies and generalizations among software components, including source code components, binary code components, and executable components.

For information about Java- and .NET-specific components, see *Chapter 13, Working with Java* on page 353 and *Chapter 17, Working with VB .NET* on page 459.

The following example shows relationships between components in a showroom reservation system:

Component diagrams are used to define object dependencies and relationships at a higher level than class diagrams.

Components should be designed in order to be reused for several applications, and so that they can be extended without breaking existing applications.

You use component diagrams to model the structure of the software, and show dependencies among source code, binary code and executable components so that the impact of a change can be evaluated.

A component diagram is useful during analysis and design. It allows analysts and project leaders to specify the components they need before having them developed and implemented. The component diagram provides a view of components and makes it easier to design, develop, and maintain components and help the server to deploy, catalog, and find components.

Component Diagram Objects

PowerDesigner supports all the objects necessary to build component diagrams.

Object	Tool	Symbol	Description
Component			Represents a shareable piece of implementation of a system. See <i>Components (OOM)</i> on page 212.
Interface			Descriptor for the externally visible operations of a class, object, or other entity without specification of internal structure. See <i>Interfaces (OOM)</i> on page 52.
Port			Interaction point between a classifier and its environment. See <i>Ports (OOM)</i> on page 62.
Part			Classifier instance playing a particular role within the context of another classifier. See <i>Parts (OOM)</i> on page 60.
Generalization			A link between a general component and a more specific component that inherits from it and add features to it. See <i>Generalizations (OOM)</i> on page 97.
Realization			Semantic relationship between classifiers, in which one classifier specifies a contract that another classifier guarantees to carry out. See <i>Realizations (OOM)</i> on page 103.
Require Link			Connects components to interfaces. See <i>Require Links (OOM)</i> on page 105.
Assembly Connector			Connects parts to each other. See <i>Assembly Connectors (OOM)</i> on page 106.
Delegation Connector			Connects parts to ports on the outside of components. See <i>Delegation Connectors (OOM)</i> on page 108.

Object	Tool	Symbol	Description
Dependency			Relationship between two modeling elements, in which a change to one element will affect the other element. See <i>Dependencies (OOM)</i> on page 100.

Creating a Component Diagram

You can create a component diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Component Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Component Diagram**.

To create a new OOM with a component diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Component Diagram** as the first diagram, and click **OK**.

Deployment Diagram Basics

A *deployment diagram* is a UML diagram that provides a graphical view of the physical configuration of run-time elements of your system.

The deployment diagram provides a view of nodes connected by communication links. It allows you to design nodes, file objects associated with nodes that are used for deployment, and relationships between nodes. The nodes contain instances of component that will be deployed into and execute upon database, application or web servers.

Deployment diagrams are used for actual deployment of components into servers. A deployment can represent the ability to use instances.

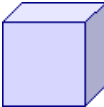

You use the deployment diagram to establish the link to the physical architecture. It is suitable for modeling network topologies, for instance.

You can build a deployment diagram to show the following views, from a high level architecture that describes the material resources and the distribution of the software in these resources, to final complete deployment into a server:

- Identify the system architecture: use nodes and node associations only
- Identify the link between software and hardware: use component instances, split up their route, identify and select the servers
- Deploy components into the servers: include some details, add physical parameters

Deployment Diagram Objects

PowerDesigner supports all the objects necessary to build deployment diagrams.

Object	Tool	Symbol	Description
Node			Physical element that represents a processing resource, a physical unit (computer, printer, or other hardware units). See <i>Nodes (OOM)</i> on page 222.
Component instance			Instance of a deployable component that can run or execute on a node. See <i>Component Instances (OOM)</i> on page 225.
Node association			An association between two nodes means that the nodes communicate to each other. See <i>Node Associations (OOM)</i> on page 229.
Dependency			Relationship between two modeling elements, in which a change to one element will affect the other element. See <i>Dependencies (OOM)</i> on page 100.

Creating a Deployment Diagram

You can create a deployment diagram in an existing OOM in any of the following ways:

- Right-click the model in the Browser and select **New > Deployment Diagram**.
- Right-click the background of any diagram and select **Diagram > New Diagram > Deployment Diagram**.

To create a new OOM with a deployment diagram, select **File > New Model**, choose to create an object-oriented model from the Model type list, choose **Deployment Diagram** as the first diagram, and click **OK**.

Components (OOM)

A *component* is a physical, replaceable part of a system that packages implementation, conforms to and provides the realization of a set of interfaces. It can represent a physical piece of implementation of a system, like software code (source, binary or executable), scripts, or command files. It is an independent piece of software developed for a specific purpose but not a specific application. It may be built up from the class diagram and written from scratch for the new system, or it may be imported from other projects and third party vendors.

A component can be created in the following diagrams:

- Component Diagram

The symbol of the component is as follows:

A component provides a 'black box' building block approach to software construction. For example, from the outside, a component may show two interfaces that describe it, whereas from the inside, it would reflect both interfaces realized by a class, both operations of the interfaces being the operations of the class.

A component developer has an internal view of the component: its interfaces and implementation classes, whereas one who assembles components to build another component or an application only has the external view (the interfaces) of these components.

A component can be implemented in any language. In Java, you can implement EJB, servlets, and JSP components, for example.

For more information on other types of components: EJB, servlets, JSP and ASP.NET, see *Chapter 13, Working with Java* on page 353 and *Chapter 17, Working with VB .NET* on page 459.

If you start developing a component with classes and interfaces in an OOM and you later want to store them in a database, it is possible to create a manual mapping of objects so that OOM objects correspond to PDM objects. Similarly, if you have an existing OOM and an existing PDM and both models must be preserved; you can handle the link between the object-oriented environment and the physical database through the *object to relational mapping*. Using this mapping, you can make your components communicate to each other and evolve in an object environment, as well as retrieve data stored in a database.

For more information on O/R Mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

Creating a Component

You can create a component in any of the following ways:

- Use the Component tool in the diagram Palette
- Select **Model > Components** to access the List of Components, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Component**
- Select **Tools > Create Component** to access the Standard Component Wizard

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

For more information on other types of components: EJB, servlets, JSP and ASP.NET, see *Chapter 13, Working with Java* on page 353 and *Chapter 17, Working with VB .NET* on page 459.

Using the Standard Component Wizard

PowerDesigner provides a wizard to help you in creating components from classes.

1. Open a class or composite structure diagram and select the class or classes that you want to include in the new component.
2. Select **Tools > Create Component** to open the Standard Component Wizard.

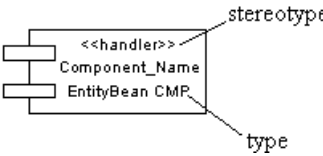

3. Type a name and a code for the component and click Next.
4. If you want the component to have a symbol and appear in a diagram, then select the Create Symbol In checkbox and specify the diagram in which you want it to appear (you can choose to create a new diagram). If you do not select this checkbox, then the component is created and visible from the Browser but will have no symbol.
5. If you want to create a new class diagram to regroup the classes selected, then select the Create Class Diagram for Component Classifiers.

Component Properties

You can modify an object's properties from its property sheet. To open a component property sheet, double-click its diagram symbol or its Browser entry in the Components folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for components.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	<p>Extends the semantics of the object beyond the core UML definition. The following standard stereotypes are available by default:</p> <ul style="list-style-type: none"> • <<Document>> - Generic file that is not a source file or an executable • <<Executable>> - Program file that can be executed on a computer system • <<File>> - Physical file in the context of the system developed • <<Library>> - Static or dynamic library file • <<Table>> - Database table <p>You can modify an existing stereotype or create a new one from an object language. You can also use the extended model definition to create new sets of stereotypes.</p> <p>For more information on how to manipulate categories and entries in the object language, see the Resource Files and the Public Metamodel chapter in the <i>Customizing and Extending PowerDesigner manual</i>.</p>
Type	<p>Defines the type of component. You can use a standard or a specific component. A standard component is useful if no specific implementation of the component has been defined. A specific component includes EJB, JSP, Servlet or ASP.NET.</p> <p>For more information on specific component types, see <i>Chapter 6, Working with Web Services</i> on page 233.</p> <p>To display the type of a component, select Tools > Display Preferences and select the Type option in the component category.</p>  <p>Whenever you change the type of a component after creation, the modification triggers a conversion from one type to another: all relevant interfaces, classes, and dependencies are automatically created and initialized. Such a change will affect some property sheets, the Check Model feature, and code generation.</p> <p>For example, if you convert a standard component to an EJB Entity Bean, it will automatically generate a Bean class and a primary key class of the EJB, as well as home and component interfaces. If you convert an EJB to a standard component, the classes and interfaces of the EJB are preserved in the model.</p>

Property	Description
Transaction	Used for a component with transactional behavior.
Class diagram	Diagram with classes and interfaces linked to the component. It is automatically created and updated. For more information, see <i>Creating a class diagram for a component</i> on page 221.
Web service	Indicates that the component is a Web service.

The following tabs list objects associated with the component:

- Related Diagrams - lists the model diagrams that are related to the component. You can add diagrams in this tab. For more information see "Defining related diagrams" in the Diagrams and Symbols chapter of the *Core Features Guide*.
- Interfaces - see *Component Property Sheet Interfaces Tab* on page 216.
- Classes - see *Component Property Sheet Classes Tab* on page 218.
- Ports - lists the ports associated with the component. You can create ports directly in this tab. For more information, see *Ports (OOM)* on page 62.
- Parts - lists the parts associated with the component. You can create parts directly in this tab. For more information, see *Parts (OOM)* on page 60.
- Files - see *Component Property Sheet Files Tab* on page 219.
- Operations - see *Component Property Sheet Operations Tab* on page 220.

Component Property Sheet Interfaces Tab

Interfaces contained in the component are interfaces exposed by the component. This indicates that the component implements the services provided by the interface.

Each component uses one or several interfaces. It also uses or requires interfaces from other components. These interfaces are visible entry points and services that a component makes available to other software components and classes. If dependencies among components originate from interfaces, these components can be replaced by other components that use the same interfaces.

Component interfaces are shown as circles linked to the component side by an horizontal or a vertical line:

The symbol of a component interface is visible if you have selected the Interface symbols display preference from **Tools > Display Preferences**. The symbol of an interface can be moved around the component symbol, and the link from the component to the interface can be extended.

If you are working with EJB, some of the interfaces have a special meaning (local interface, remote interface, etc...).

For more information on EJB interfaces, see *Defining Interfaces and Classes for EJBs* on page 373.

Interfaces of a component can be in the same model or in another model. If they are in another model, you can use external shortcuts of interfaces.

You can define an interface for a component from the Interfaces tab of the component property sheet.

Defining Interfaces for a Component

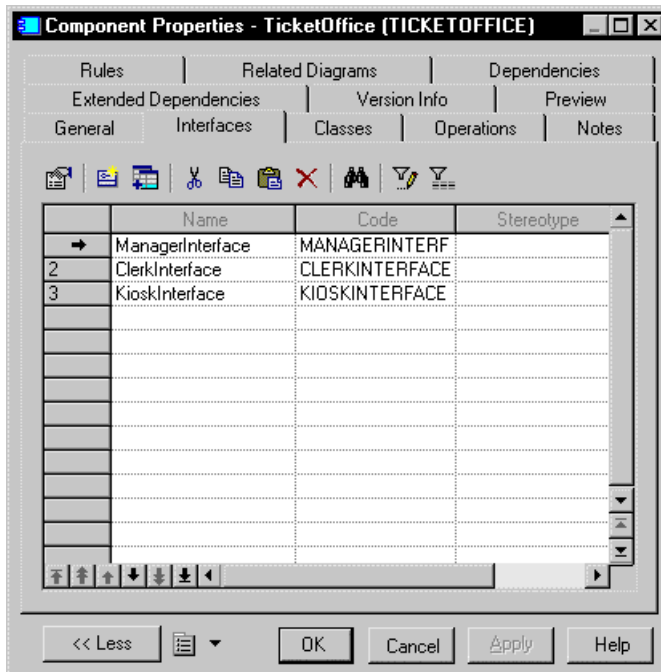

To define interfaces for a component:

1. Click the Create a New Interface tool to create a new interface. The interface property sheet is displayed.
2. Type a name and a code and click OK.

or

Click the Add Objects tool to display a Selection window.

Select the interfaces you want to attach to the component and click OK.

The interfaces appear in the list, and their definitions are added to the current component definition. Interfaces are created in the same package as the component.

Component Property Sheet Classes Tab

Classes contained in the component are classes implementing the component.

A component has one or several classes. It usually uses one implementation class as the main class, while other classes are used to implement the functions of the component. Typically, a component consists of many internal classes and packages of classes but it may also be assembled from a collection of smaller components.

These classes have no symbol in the component diagram, unlike interfaces. However, the relationship between the class and the component is visible from the Classes tab of the component property sheet, and from the Components tabbed page in the Dependencies tab of the class property sheet.

Classes of a component can be in the same model or in another model. If they are in another model, you can use external shortcuts of classes.

You can define a class for a component from the Classes tab of the component property sheet.

Defining a Class for a Component

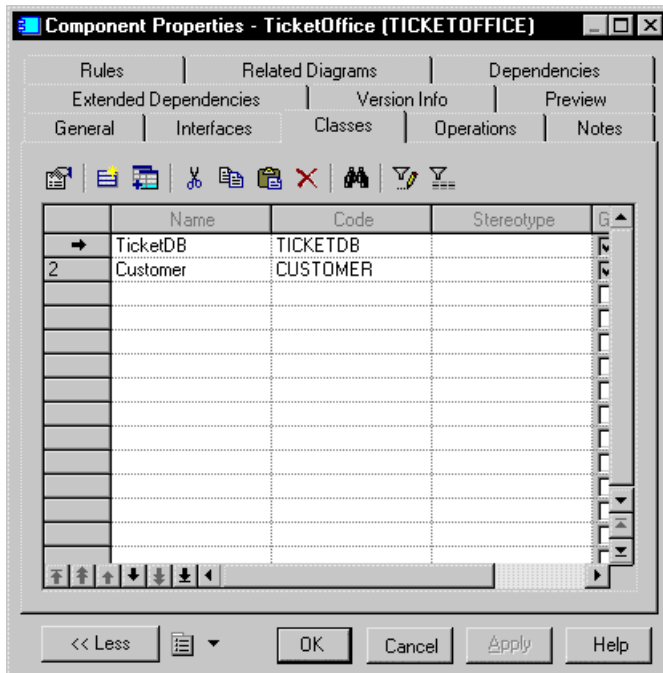

To define a class for a component:

1. Click the Create a New Class tool to create a new class. The class property sheet is displayed.
2. Type a name and a code and click OK.

or

Click the Add Objects tool to display a Selection window.

Select the classes you want to attach to the component and click OK.

The classes appear in the list, and their definitions are added to the current component definition. Classes are created in the same package as the component.

Component Property Sheet Files Tab

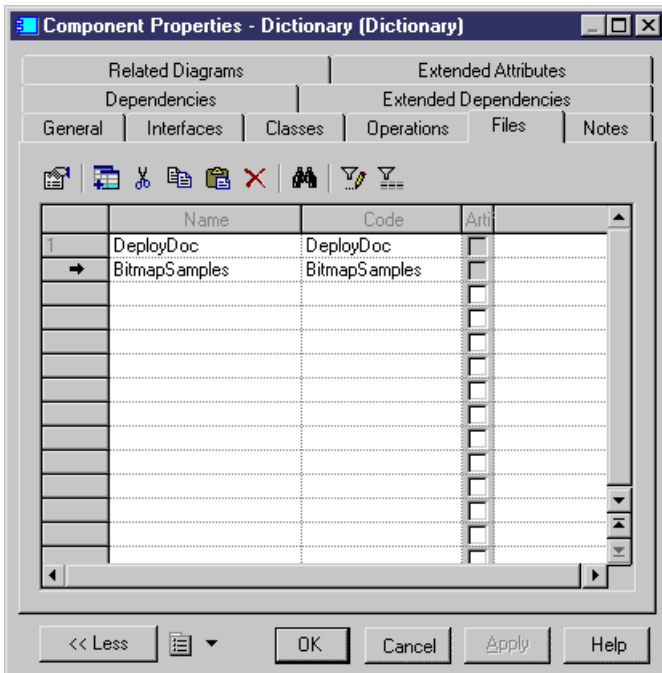

You can define file objects to be attached to a component from the Files tab in the component property sheet.

This file object is a file containing text or images. It can be attached to a component that you will later deploy into a server. The advantage of this is that the information contained within the file object travels with the component, and it is deployed at the same time as the component.

Defining a File Object for a Component:

To define a file object for a component:

1. Click the Add Objects tool to display a Selection window.
2. Select the file object you want to attach to the component and click OK.

The name of the file object is displayed in the list.

3. Click OK to close the component property sheet.

Component Property Sheet Operations Tab

Operations contained in the component are operations declared in the component interfaces.

You can select a specific interface, or you can select all interfaces of the component and display their properties from the list of the Operations tab in the component property sheet.

It is not possible however to create an operation from the Operations tab of the component property sheet, this tab is only used to view the operations of the component. You need to create an operation directly from the interface property sheet.

Viewing Operations of a Component

To View Operations of a Component:

1. Select one interface or <All interfaces> from the list.
2. The operations of the interface appear in the list. You can double-click an arrow at the beginning of a line to display an operation property sheet.

Creating a Class Diagram for a Component

You can create a class diagram for a selected component to have an overall view of the classes and interfaces associated with the component. You can only create one class diagram per component.

The Create/Update Class Diagram feature from the component contextual menu, acts as follows:

- Creates a class diagram if none exists
- Attaches a class diagram to a component
- Adds symbols of all related interfaces and classes in the class diagram
- Completes the links in the diagram

This feature also allows you to update a class diagram after you have made some modifications to a component.

The Open Class Diagram feature, available from the component contextual menu, opens the specific class diagram if it exists, or it creates a new default class diagram.

For EJB components for example, the Open Class Diagram feature opens the class diagram where the Bean class of the component is defined.

If you delete a component that is attached to a class diagram, the class diagram is also deleted. Moreover, the classes and interfaces symbols are deleted in the class diagram, but the classes and interfaces objects remain in the model.

Right-click the component in the component diagram and select Create/Update Class Diagram from the contextual menu.

A new class diagram, specific to the component, is displayed in the diagram window and the corresponding node is displayed under in the Browser. You can further create objects related to the component in the new class diagram.

Note: To open the class diagram for a component, right-click the component in the diagram and select Open Class Diagram from the contextual menu or press ctrl and double-click the component.

Deploying a Component to a Node

Deploying a component to a node allows you to set an instance of the component within a node. You can deploy a component from the component diagram or from the Browser. After deployment, a shortcut of the component and a new component instance are created within the deployment node.

You can only select one component to deploy at a time.

1. Right-click the component symbol and select Deploy Component to Node to open the Component to Node Deployment window:

2. Select either an existing node to deploy the component to or click the New Node button to create a new node and deploy the component to it.
3. Click OK to create a new component instance inside the selected node.

Nodes (OOM)

A node is the main element of the deployment diagram. It is a physical element that represents a processing resource, a real physical unit, or physical location of a deployment (computer, printer, or other hardware units).

In UML, a node is defined as Type or Instance. This allows you to define for example 'BackupMachine' as node Type, and 'Server:BackupMachine' as Instance. As a matter of simplification, PowerDesigner handles only one element, called node, which actually represents a node instance. If you need to designate the type, you can use a stereotype for example.

A node can be created in the following diagrams:

- Deployment Diagram

The symbol of a node is a cube:

A node *cannot* contain another node, however it can contain component instances and file objects: the software component instances and/or associated file objects that are executed within the nodes. You can use shortcuts of component as well.

You can add a component instance from the node property sheet. You can display the list of component instances in the node symbol as well, by selecting the option Components in the node display preferences.

Composite View

You can add component instances and file objects to a node by dropping them onto the node symbol. By default, these sub-objects are displayed inside the symbol. To disable the display of these sub-objects, right click the node symbol and select **Composite View > None**. To redisplay them, select **Composite View > Editable**.

For more information about symbol composite views, see "Using Composite View to Display Sub-Objects within a Symbol" in the Diagrams and Symbols chapter of the *Core Features Guide*.

Creating a Node

You can create a node in any of the following ways:

- Use the Node tool in the diagram Palette
- Select **Model > Nodes** to access the List of Nodes, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Node**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Node Properties

You can modify an object's properties from its property sheet. To open a node property sheet, double-click its diagram symbol or its Browser entry in the Nodes folder. The following sections detail the property sheet tabs that contain the properties most commonly entered for nodes.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.

Property	Description
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the node.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Cardinality	Specific numbers of instances that the node can have, for example: 0..1.
Network address	Address or machine name.

Node Property Sheet Component Instances Tab

The node property sheet includes a Component Instances tab that lists all instances of components that can run or execute on the current node. It allows you to define component instances directly from the node definition without any drill down into the node diagram. Once defined, the component instances can be displayed within the node symbol, provided the Component Instances option is selected in the node display preferences.

For more information on component instances, see *Component Instances (OOM)* on page 225.

Node Diagrams

You can expand a node in a diagram owned by the node, in order to define its contents: the associated component instances and its file objects.

This diagram is a deployment diagram within a node. It is called a *node diagram*.

Creating a Node Diagram

You create a node diagram from the symbol of the parent node.

Press ctrl and double-click the parent node symbol from the deployment diagram.

A default deployment diagram opens in the diagram window. The node of the parent node is marked with a + sign in the Nodes category of the Browser.

If you expand the node of the parent node, you see that a deployment diagram is automatically created. It is the node diagram in which you can create any component instances and file objects associated with the node.

Opening a Node Diagram

You can open a node diagram using the following methods:

- Press ctrl and double-click on the parent node symbol.
or
Select Open Diagram from the contextual menu of the parent node.

The node diagram opens in the diagram window.

Closing a Node Diagram

You can close a node diagram using the following methods:

- Press ctrl + u in the node diagram to go up to the parent diagram.
or
Select **Diagram > Go Up One Level** from the contextual menu.

Component Instances (OOM)

A component instance is an instance of a component that can run or execute on a node. Whenever a component is processed into a node, a component instance is created. The component instance plays an important role because it contains the parameter for deployment into a server.

A component instance can be created in the following diagrams:

- Deployment Diagram

The component instance symbol is the same as the component symbol in the component diagram.

The component instance relationship with the node is similar to a composition; it is a strong relationship, whereas the file object relationship with the node is different because several nodes can use the same file object according to deployment needs.

Drag and Drop a Component in a Deployment Diagram

You can drag a component from the Browser and drop it into a deployment diagram to automatically create a component instance linked to the component.

The component instance that inherits from the component automatically inherits its type: the type of the component is displayed in the property sheet of the component instance.

Deploy Component to Node from the Component Diagram

You can create a component instance from a component. To do this, use the Deploy Component to Node feature. This feature is available from the contextual menu of a component (in the component diagram) or from the Browser. This creates a component instance and attaches the component instance to a node. If you display the node symbol in a deployment diagram, the component instance name is displayed within the node symbol to which it is attached.

For more information, see *Deploying a component to a node* on page 221.

Creating a Component Instance

You can create a component instance in any of the following ways:

- Use the Component Instance tool in the diagram Palette
- Select **Model > Component Instances** to access the List of Component Instances, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Component Instance**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Component Instance Properties

You can modify an object's properties from its property sheet. To open a component instance property sheet, double-click its diagram symbol or its Browser entry in the Component instances folder.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the component instance.
Stereotype	Extends the semantics of the object beyond the core UML definition.

Property	Description
Cardinality	Specific number of occurrences that the component instance can have, for example: 0...1.
Component	Component of which the component instance is an instance. If you change the component name in this box, the name of the component instance is updated in the model.
Component type	Read-only box that shows the type of the component from which the component instance is coming.
Web service	Indicates that the component instance is an instance of a Web service component.

If you want to list all component instances of a component, click the Component Instances tabbed page in the Dependencies tab of the component property sheet.

Files (OOM)

A file object can be a bitmap file used for documentation, or it can be a file containing text that is used for deployment into a server.

A file can be created in the following diagrams:

- All Diagrams

The symbol of a file object is as follows:

File_1

The file object can have a special function in a deployment diagram, where it can be specified as an artifact (by selecting the Artifact property) and generated during the generation process.

When you want to associate a file object to a node, you can drag a dependency from the file object to the node:

You can also use ctrl and double-click on the parent node symbol, then create the file object into the node diagram.

You can edit a file object by right-clicking its symbol in the deployment diagram and selecting **Open Document** or **Open With > text editor of your choice** from the contextual menu.

For more information on file objects, see "File Objects" in the Objects chapter of the *Core Features Guide*.

Creating a File Object

You can create a file object in any of the following ways:

- Use the File tool in the diagram Palette
- Select **Model > Files** to access the List of Files, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > File**
- Drag and drop a file from Windows Explorer to your diagram or the PowerDesigner Browser

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

File Object Properties

You can modify an object's properties from its property sheet. To open a file object, right-click its diagram symbol or its Browser entry in the Files folder and select Properties from the contextual menu.

The General Tab contains the following properties:

Property	Description
Name	Specifies the name of the item, which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the object.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Location Type	Specifies where PowerDesigner can find the file. You can choose between: <ul style="list-style-type: none">• Embedded File – saved within the project• External File• URL
Location	Specifies the path to the file. This option is not available if you specify an embedded file.
Extension	Specifies the extension to be used when generating an embedded file.
Generate	The file object is automatically included among the objects generated from the model when you launch a generation process.

Property	Description
Artifact	<p>The code of an artifact file object is generated as part of the generation process. Only file objects that have the Artifact property selected are generated. Their contents may be edited using the editor of your choice.</p> <p>An artifact file object can be edited in the internal editor of PowerDesigner if its extension corresponds to an extension defined in the Editors page of the General Options dialog box (Tools menu), and if the <internal> keyword is defined in the Editor Name and Editor Command columns for this extension. In this case the Contents tab is displayed in the file object property sheet, it allows you to directly edit the content of the artifact file object.</p>

For more information on file objects, see "File Objects" in the Objects chapter of the *Core Features Guide*.

Node Associations (OOM)

You can create associations between nodes, called node associations. They are defined with a role name and a multiplicity at each end. An association between two nodes means that the nodes communicate with each other, for example when a server is sending data to a backup server.

A node association can be created in the following diagrams:

- Deployment Diagram

A node association symbol is as follows:

Creating a Node Association

You can create a node association in any of the following ways:

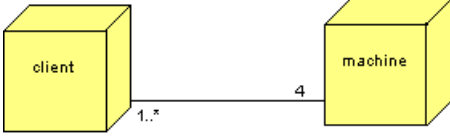

- Use the Node Association tool in the diagram Palette
- Select **Model > Node Associations** to access the List of Node Associations, and click the Add a Row tool
- Right-click the model or package in the Browser, and select **New > Node Association**

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Node Association Properties

You can modify an object's properties from its property sheet. To open a node association property sheet, double-click its diagram symbol or its Browser entry in the Node Associations folder.

The General Tab contains the following properties:

Property	Description
Name	The name of the item which should be clear and meaningful, and should convey the item's purpose to non-technical users.
Code	Specifies the technical name of the object, which is used for generating code or scripts.
Comment	Descriptive comment for the node association.
Stereotype	Extends the semantics of the object beyond the core UML definition.
Role A	One side of a node association. Each role can have a name and a cardinality and be navigable.
Node A	Name of the node at one end of the node association. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Multiplicity A	<p>Multiplicity indicates the maximum and minimum number of instances of the node association. You can choose between:</p> <ul style="list-style-type: none"> • 0..1 – zero or one • 0..* – zero to unlimited • 1..1 – exactly one • 1..* – one to unlimited • * – none to unlimited <p>For example, in a computer environment, there can be 100 clients and 100 machines but there is a constraint that says that a machine can accept at most 4 clients at the same time. In this case, the maximum number of instances is set to 4 in the Multiplicity box on the machine side:</p> 
Role B	One side of a node association. Each role can have a name and a cardinality and be navigable.

Property	Description
Node B	Name of the node at the other end of the node association. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object.
Multiplicity B	Multiplicity indicates the maximum and minimum number of instances of the node association. For more details, see Multiplicity A, above.

CHAPTER 6 Working with Web Services

A Web service is a service offered via the web. The principle on which a Web service works is the following: a business application sends a request to a service at a given URL address. The request can use the SOAP protocol over HTTP. The service receives the request, processes it, and returns a response. An example that is most commonly used for a Web service is a stock quote service in which the request asks for the price of a specific stock and the response gives the stock price.

In an OOM, you design a Web service as a *component* (EJB, servlet, or standard component) that includes a Web service implementation class.

When you work with Web services in an OOM, you use the class, component and deployment diagrams. They allow you to do the following:

- Create new Web Service component
- Reverse engineer WSDL to create Web Service component
- Browse UDDI to search WSDL
- Generate WSDL from Web Service component definition
- Generate server side Web Services code for Java (AXIS, JAXM, JAX-RPC, Web Services for J2EE)
- Generate server side Web Services code for .NET (C# and VB .NET)
- Generate client proxy for Java
- Generate client proxy for .NET
- Reverse engineer for Java and .NET

What Do You Need to Work with Web Services?

You need a Java, C# or Visual Basic .NET compiler.

For Java, you also need a WSDL-to-Java and a Java-to-WSDL tool to generate Java proxy code and JAX-RPC compliant server side code. The WSDL-to-Java and Java-to-WSDL tools are used by the extended model definition named 'WSDL for Java'. For example, the WSDP (Web Service Developer Pack) provides a XRPPC tool, Apache AXIS provides a wsdl2java and a java2wsdl tool.

The WSDP and the appropriate SDK can be downloaded from the Sun Java Development Site: <http://java.sun.com/index.jsp>.

Apache AXIS can be downloaded from: <http://ws.apache.org/axis>.

To generate client proxy code for .NET, you will need to use the WSDL.exe included in Visual Studio .NET and declare the path to the WSDL.exe in the General Options dialog box (**Tools > General Options**) when you create the WSDL environment variables.

Defining Web Services Tools

A Web Service is an interface that describes a collection of operations that are accessible on the network through SOAP messages.

Web services operate over the Internet or a corporate intranet in the exact same way as you locate a web site: either you type in the URL address or you use a search engine to locate the site. You may know the address of the Web service you want to invoke, the address of its interface (WSDL for example), or you must search for the service by querying a Web service registry. The UDDI specification defines a standard mechanism for publishing and locating the existence of businesses and the services they provide.

WSDL is a language that describes what a Web service is capable of and how a client can locate and invoke that service. The Web Services Description Language (WSDL) 1.1 document, available at <http://www.w3.org/TR/wsdl>, describes WSDL documents as follows:

"A WSDL document defines services as collections of network endpoints, also called ports. In WSDL, the abstract definition of endpoints and messages is separated from their concrete network deployment. This allows the reuse of abstract definitions: *messages* are abstract descriptions of the data being exchanged, and *port types* are abstract collections of operations. The concrete protocol and data format specifications for a particular port type constitutes a reusable binding. A port is defined by associating a network address with a reusable binding, and a collection of ports defines a service. Hence, a WSDL document uses the following elements in the definition of network services:

- *Types*: a container for data type definitions using some type system (such as XSD)
- *Message*: an abstract, typed definition of the data being communicated
- *Operation*: an abstract description of an action supported by the service
- *Port Type*: an abstract set of operations supported by one or more endpoints
- *Binding*: a concrete protocol and data format specification for a particular port type
- *Port*: a single endpoint defined as a combination of a binding and a network address
- *Service*: a collection of related endpoints"

Interface and Implementation

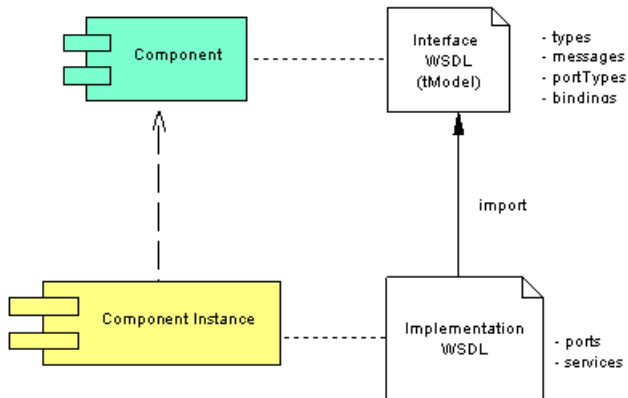

WSDL is used to define the Web service interface, the Web service implementation, or both. As a result, it is possible to use two WSDL files, one for the interface and one for the implementation.

In an *interface WSDL*, you declare the procedures that allow you to create a Web service.

In an *implementation WSDL*, you define how to implement these procedures through services and ports (access endpoints URLs).

In an OOM, an interface WSDL is associated with a component, and an implementation WSDL is associated with a component instance. You can save both WSDL files within the model.

For detailed information about WSDL, see <http://www.w3.org/2002/ws/desc>.

What Is SOAP?

SOAP stands for Simple Object Access Protocol. It is a protocol based upon XML for exchange of information in a distributed environment. It represents the invocation mechanism within a Web service architecture. WSDL allows a user to understand which format of the SOAP message should be sent to invoke the service and what is the expected return message format.

What Is UDDI?

UDDI stands for Universal Description Discovery and Integration. It is an XML-based registry for businesses worldwide. This registry lists all Web services on the Internet and handles their addresses.

In UDDI, an organization or a company, called a *businessEntity* usually publishes a WSDL to describe Web services interfaces as *tModel*. Another company may implement it, and then publish in the UDDI the following items that describe how to invoke the Web service:

- The company, called *businessEntity*
- The service, called *businessService*
- The access endpoints, called the *bindingTemplate*
- The specification, called the *tModel*

Supported Web Services

For Web Services Implemented Using .NET

PowerDesigner generates .asmx files for C# or VB .NET, WSDL files and client proxies in C# or VB .NET.

For Web Services Implemented Using Java

PowerDesigner allows you to use one of the following models: AXIS, JAXM, JAX-RPC and Web Services for J2EE (Stateless Session Bean).

Defining Web Services Targets

The following OOM languages support Web services:

The following OOM languages support Web services:

- Java
- .NET: C# and Visual Basic .NET

In general, a WSDL can be generated by the server where the Web service is deployed. As a result, the WSDL generated by the server contains both the interface and implementation definition.

When you work with Java, C# or VB.NET in an OOM, an *extended model definition* is automatically attached to the model. It is used to complement the definition of these languages within the context of Web services.

Defining Web Service Components

A Web service is represented as a component that you can display in a component diagram. From a component diagram, you can display the Web service interface and implementation code, eventually, you can also deploy Web service components to nodes if you want to describe deployment of components into servers.

For more information on how to deploy components, see *Deploying a Component to a Node* on page 221.

A component can be a Web service Interface or a Web service Implementation type. You have to check the Web Service check box in the component property sheet to declare your component as a Web service.

The following Web service types are supported for the Java language:

- *Java Web Service*: exposes a Java class with the .jws extension as a Web service using Apache Axis.
- *Axis RPC*: exposes a Java class as a Web service using the Apache Axis RPC model.
- *Axis EJB*: exposes a Stateless Session Bean as a Web service using the Apache Axis EJB model.
- *JAX-RPC*: uses a Java class and an interface to implement the JAX-RPC model.
- *JAXM*: exposes a Servlet as a Web service using JAXM.
- *Web Service for J2EE*: exposes a Stateless Session Bean as a Web service using the Web Service for J2EE (JSR109) model.

Web Service Component Properties

You can double-click any Web service component to display its properties.

Web Service Tab of the Component

The Web Service tab in the component property sheet includes the following properties:

Property	Description
Web service class	Web service class name. You can click the Properties tool beside this box to display the class property sheet, or click the Create tool to create a class. If the Web service component is a Stateless Session Bean, the Web service class is the bean class as well
Application namespace	Usually a package name within the server. The application namespace is used to generate the URL for the Web service in the server. By default, it uses the component package code or the model code, but you can modify it
WSDL URL	Indicates where the WSDL is published on the web.
Web service type	Interface or Implementation type. Interface refers to a component that defines the service interface only. Implementation refers to a component that implements a service interface
Use external WSDL	Indicates that the WSDL is published at a specific URL and that the original WSDL will be preserved. When you import a WSDL, this option is selected by default

Note

For Session Beans, the Web service class and the bean class are synchronized; if you apply some changes in the EJB tab, the Web Service tab is automatically synchronized.

A Web service component may have an external WSDL if it is created from an external WSDL URL. In this case, the WSDL may be published by another organization, and you can either use it, or implement it. A Web service component created from a class can have its own WSDL.

You cannot change the WSDL URL of an external WSDL.

WSDL Tab of the Component

The WSDL tab in the component property sheet includes the following properties:

Property	Description
Target name-space	URL linked to a method that ensures the uniqueness of the Web service and avoid conflicts with other Web services of the same name. By default, it is <i>http://tempuri.org</i> for .NET and <i>urn:%Code%Interface</i> for Java. It is recommended to change it to ensure the service name uniqueness
Prefix	Allows you to define the target namespace prefix
Encoding style	You can choose the SOAP data types (soap:xxx) or the XML-Schema data types (xsd:xxx) for the WSDL
Comment	Description of the WSDL file. It is used during WSDL generation
WSDL editor	You can use the text zone at the bottom of this tab to edit the contents of the WSDL. When you click the User-Defined tool, you make the contents user-defined. Once the tool is clicked, the contents can be overridden. When a WSDL is not user-defined, it is regenerated each time and can be displayed in the Preview tab of the component property sheet

WSDL Schema Tab of the Component

The WSDL Schema tab in the component property sheet includes a text zone that contains some shared schema definitions from the WSDL schema. This part of the schema defines the data types used by the input, output and fault messages.

The other part of the schema is defined within the different Web methods (operations) as SOAP input message data types, SOAP output message data types, and SOAP fault data types.

For more information on the other part of the WSDL schema, see *Defining SOAP data types of the WSDL schema* on page 252.

Preview Tab of the Component

You can preview the code of a Web service component by clicking the Preview tab in the component property sheet. It allows you to preview the code of the following items:

- Web Service class and interfaces (for Java)
- .ASMX file (for .NET)

Note: You can display some of the tabs of a component property sheet by right-clicking the component symbol in the diagram and selecting the appropriate tab from the contextual menu.

Extended Attributes Tab of the Component

You can preview the extended attributes associated with a Web service component by clicking the UDDI or the Extended attributes tab in the component property sheet.

Name	Internal code	Description
SOAP binding style	SoapBindingStyle	Defines the SOAP binding style. It could be a document or rpc
SOAP binding transport	SoapBindingTransport	Defines the SOAP binding transport URI
SOAP body namespace	SoapBodyNamespace	Defines the namespace of the XML schema data types in the WSDL
Business name	BusinessName	Stores the name of the business found in a UDDI registry
Business description	BusinessDescription	Stores the business description of the Web Service found in a UDDI registry
Business key	BusinessKey	Stores the key of the business found in a UDDI registry
Namespaces	Namespaces	Stores additional namespace that are not automatically identified by PowerDesigner
Service name	ServiceName	Stores the name of the service found in a UDDI registry
Service description	ServiceDescription	Stores the service description of the Web Service found in a UDDI registry
Service key	ServiceKey	Stores the key of the service found in a UDDI registry
tModel name	tModelName	Stores the name of the tModel found in a UDDI registry
tModel key	tModelKey	Stores the key of the tModel found in a UDDI registry
tModel URL	tModelURL	Stores the URL of the tModel found in a UDDI registry. It allows you to retrieve the WSDL
UDDI operator URL	UDDIOperatorURL	Stores the URL of the UDDI registry operator URL used to find the WSDL

Creating a Web Service with the Wizard

You can create a Web service with the *wizard* that will guide you through the creation of the component. The wizard is invoked from a *class diagram* and is only available if you use the Java or the .NET family.

You can either create a Web service without selecting any class, or use the standard approach that consists in selecting an existing class first and then start the wizard from the contextual menu of the class.

You can also create several Web services of the same type by selecting several classes at the same time. The wizard will automatically create one Web service per class. The classes you have selected in the class diagram become Web service classes, they are renamed to match the naming conventions standard, and they are linked to the new Web service component.

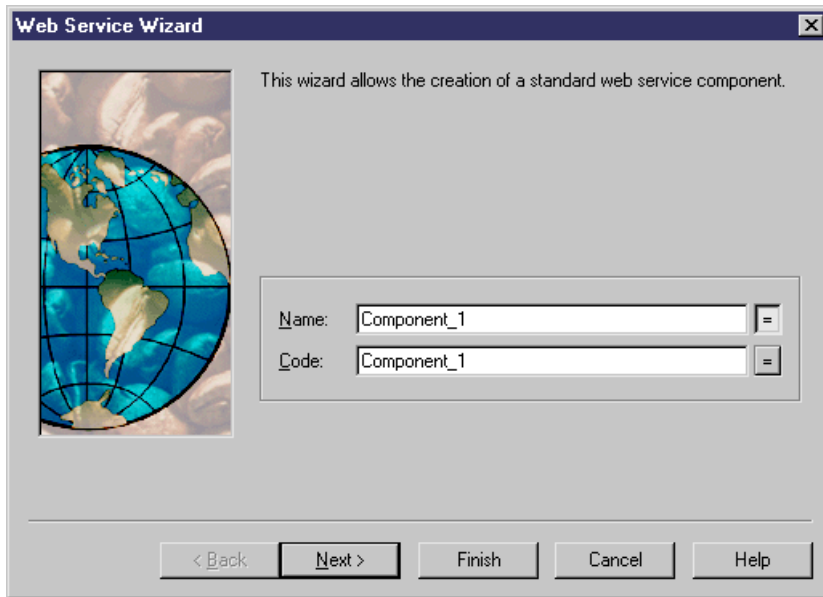

Note: You must create the Web service component within a package so that the package acts as a namespace.

The wizard for creation of Web services lets you define the following parameters:

Property	Description
Name	Name of the Web service component
Code	Code of the Web service component
Web service type	Interface or Implementation. Interface refers to a component that defines the service interface only. Implementation refers to a component that implements a service interface
Component type	The component type depends on the web service type. You can select among a list of web service interface or implementation protocols
Web service implementation class	Defines the class that is used to implement the Web service
Create symbol	Creates a component symbol in the diagram specified beside the Create symbol In check box. If a component diagram already exists, you can select one from the list. You can also display the diagram properties by selecting the Properties tool
Create Class Diagram for component classifiers	Available only for stateless session beans and servlets. It creates a class diagram with a symbol for each class and interface. If you have selected classes and interfaces before starting the wizard, they are used to create the component. This option allows you to display these classes and interfaces in a diagram

1. Select **Tools > Create Web Service Component** from a class diagram.

The Web Service Wizard dialog box is displayed.

2. Type a name and code for the Web service component and click Next.

Note: If you have selected classes before starting the wizard, some of the following steps are omitted because the different names are created by default according to the names of the selected classes.

When you create a Web service with the wizard, you have to select the type of the Web service and the type of the component that is used as a source. The following table maps available component types to Web service types in Java:

Component type	Java service interface	Java service implementation	Use
Standard		—	Java class
Axis RPC	—		Java class
Axis EJB	—		EJB Stateless Session Bean
Java Web Service (JWS)	—		Java class with .jws extension
JAXM	—		Java Servlet
JAX-RPC	—		Java class
Web Service for J2EE	—		EJB Stateless Session Bean

= allowed

— = not allowed

3. Select a Web service type and a component type and click Next.
4. Select a Web service implementation class and click Next.
5. At the end of the wizard, you have to define the creation of symbols.

When you have finished using the wizard, the following actions are executed:

- A Web service component flagged as 'Web service' is created
- A Web service implementation class is created and visible in the Browser. It is named after the original class if you have selected a class before starting the wizard. If you have not selected a class beforehand, it is prefixed after the original default component name to preserve coherence
- A default operation with the "Web method" flag is created
- Depending on the component type, required interfaces associated with the component are added

Creating a Web Service from the Component Diagram

You can also create a web service from the component diagram.

1. Click the Component tool in the palette and click in the diagram to create a component.
2. Click the Pointer tool or right-click to release the Component tool.
3. Double-click the component symbol to display the property sheet.
4. Select the Web Service check box in the General tab.
5. Click OK.

Defining Data Types for WSDL

WSDL uses XML Schema to define data types for message structures.

WSDL Data Type Mappings

To generate WSDL, it is necessary to map Java or .NET types to XML types.

In an OOM, there are three data type maps named WSDL2Local Data Types, Local2SOAP Data Types, and Local2XSD Data Types. They are defined in the WSDL extended model definition.

- The WSDL2Local map is used to convert WSDL types to Java or .NET types
- The Local2SOAP map is used to convert Java or .NET types to SOAP types for SOAP encoding
- The Local2XSD map is used to convert Java or .NET types to XML Schema types for XML Schema encoding

Selecting WSDL Data Types

If you need to use a specific data type, you can select the WSDL data type for the operation return type or the parameter type.

You can select a WSDL data type from the list in the operation and parameter property sheets. This box includes basic data types for XML Schema encoding or SOAP encoding.

You can also click the Properties button beside the WSDL data type box to open the WSDL Schema tab in the component property sheet. This tab shows the contents of the WSDL schema.

As long as the WSDL data type is not manually changed, it is synchronized with the Java or .NET data type. You can use the Preview tab in the property sheet of the class to verify the code at any time.

1. From the Web Method tab in the operation property sheet, select or type a new data type in the WSDL data type box.

or

From the parameter property sheet, select or type a new data type from the WSDL data type box.

2. Click Apply

Declaring Data Types in the WSDL

Classes used as data types are declared as Complex Types inside the <types> section of WSDL.

Web Service Implementation Class

A Web service requires one implementation class. This class is used to implement the Web service.

An implementation class can only be associated with one Web service component. In .NET languages, the implementation class can be generated inside the .asmx file or outside.

Detail Tab of the Class

The Detail tab in the class property sheet includes the following properties:

Property	Description
Web service component	Web service component name linked to the Web service class. You can click the Properties tool beside this box to display the component property sheet
Serialization class	Class used to convert an object into a text or binary format. You can click the Properties tool beside this box to display the class property sheet
Deserialization class	Class used to convert a text, XML or binary format into an object. You can click the Properties tool beside this box to display the class property sheet

Java

In Java, a Web service class can have a *serialization* and a *deserialization* class.

Preview Tab of the Class

You can preview the code of a class by clicking the Preview tab in the class property sheet. It allows you to preview the code of the following items:

- The Web service implementation class in Java
- The .ASMX file in .NET
- The interface WSDL generated from the component and implementation class in Java and .NET (it is in read-only mode)

Managing Web Service Methods

You can define one or several methods as part of a Web Service. In PowerDesigner, you use operations to create Web service methods.

Creating a Web Service Method

A Web service method is an operation with the Web Service Method property selected.

A web service method can call other methods that are not exposed as Web service methods. In this case, these internal methods are not generated in the WSDL.

Web service methods can belong to the component implementation class or to component interfaces.

Interfaces linked to a Web service component can be used to design different groups of methods representing different port types.

A component interface containing at least one operation with the Web Service Method property selected is considered as a port type.

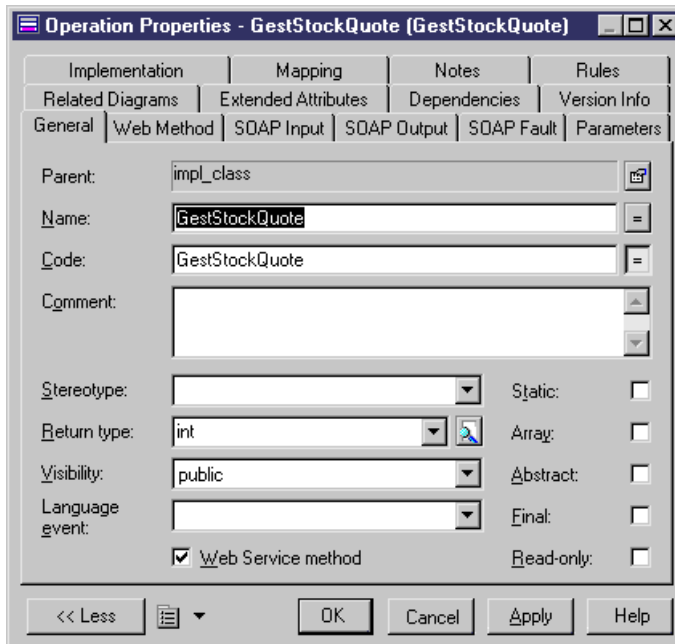

Interface methods use the same extended attributes as classes methods for WSDL customization, as explained in *Defining Web service method extended attributes* on page 251.

Three extended attributes are used to decide which Port Type should be generated: SOAPPortType, HttpGetPortType and HttpPostPortType. If a Web method is created in an interface, only the SOAPPortType attribute is set to True. This method is automatically added to the implementation class of the component.

For JAXM Web Service component, the implementation of the Web Service must be done in the onMessage() method. To be able to generate the correct WSDL, you have to declare a Web Service method without implementation to define the input SOAP message and the output SOAP message.

For more information on method implementation see *Implementing a Web service method in Java* on page 246 and *Implementing a Web service method in .NET* on page 251.

1. Open the property sheet of the Web Service class or interface.
2. Click the Operation tab, then click the Insert a row tool to create a new operation.
3. Click Apply and click the Properties tool to display the operation property sheet.
4. Select the Web Service method check box in the General tab.

5. Click OK.

Web Service Method Properties

When the Web Service method check box is selected in the operation property sheet, a Web Method tab is displayed. The Web Method tab in the operation property sheet includes the following properties:

Property	Description
SOAP extension class	Used for .NET. At creation of the class, new default functions are added. In .NET, a method can have a SOAP extension class to handle the serialization and de-serialization for the method and to handle security of other SOAP extensions features. You can use the tools to the right of the list to create an object, browse the complete tree of available objects or view the properties of the currently selected object

Property	Description
WSDL data type	Data type for the return type. It includes basic data types from the object language and complex data types from the WSDL Schema. You can click the Properties tool beside this box to display the WSDL Schema tab of the component property sheet. This tab shows the contents of the WSDL schema

The SOAP Input tab defines the name and schema of the SOAP input message element.

The SOAP Output tab defines the name and schema of the SOAP output message element.

The SOAP Fault tab defines the default name and schema of the SOAP fault message element.

Implementing a Web Service Method in Java

To implement a Web service method, you have to define the following:

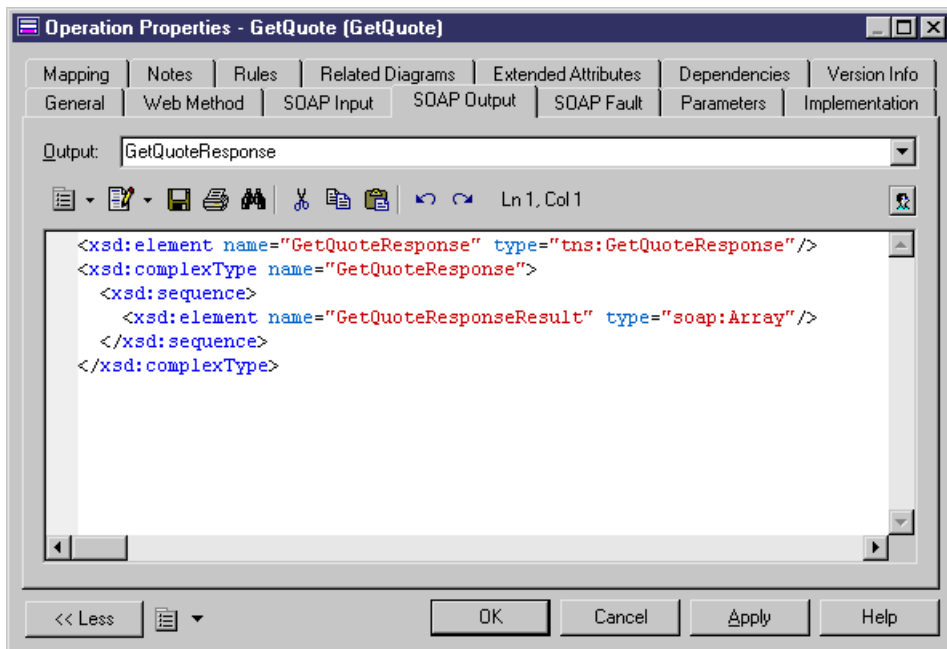

- The operation return type
- The operation parameters
- The operation implementation

Defining the Return Type of an Operation

To define the return type of an operation you have to specify:

- *The return type for the Java method:* in the General tab of the operation property sheet. If the return value in Java is a Java class or an array of Java class, PowerDesigner will generate an output message type based on the return class structure
- *The output message type for WSDL:* for simple return value, the output message type for WSDL can be defined in the Web Method tab of the operation property sheet

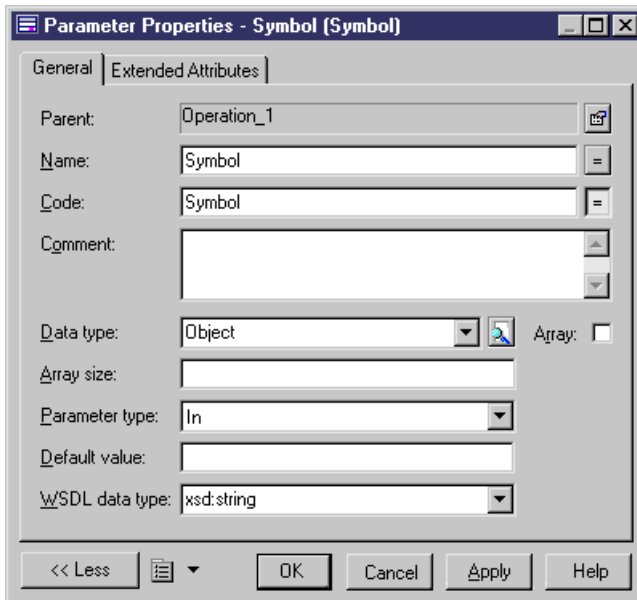

For more complex return types, you can manually define the output message schema using the SOAP Output tab of the operation property sheet.

Defining the Parameters of an Operation

To define the parameters of an operation, you have to specify:

- The *parameters type* for the Java method using the Data Type list in the Parameter property sheet
- The *input message type* for WSDL using the WSDL Data Type list in the Parameter property sheet. This list displays basic data types from the object language and complex data types from the WSDL Schema. You can click the Properties tool beside this box to display the WSDL Schema tab of the component property sheet. This tab shows the contents of the WSDL schema

For simple parameter values, the input message type is generated from the WSDL types of the parameters. If a parameter is a class or an array of class, PowerDesigner will only generate SOAP binding.

For detailed information about SOAP, see <http://www.w3.org/2000/xml/Group>.

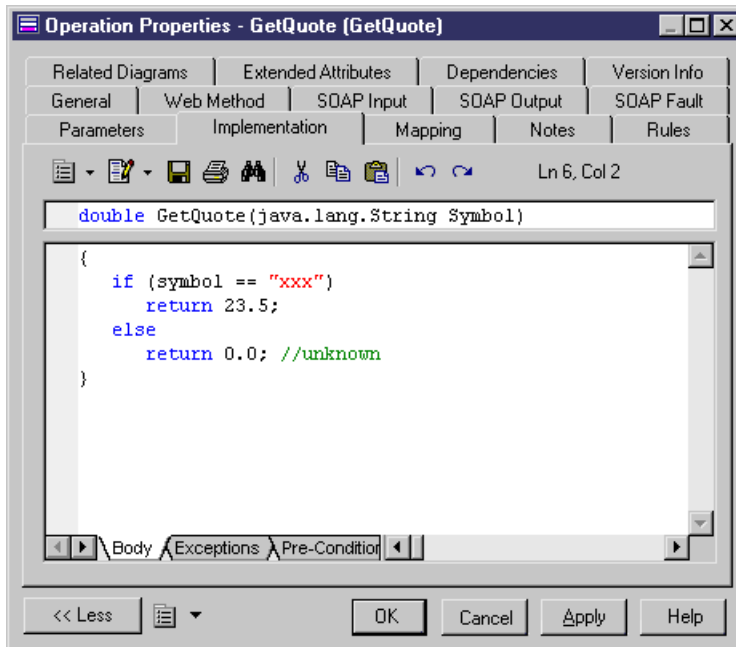

For more complex parameter types and input message types, you can manually define the input message schema using the SOAP Input tab in the operation property sheet.

Implementing the Operation

You implement a Web Service method as a normal Java method.

The following example, shows the implementation of Web service method GetQuote.

For a Web Service method in a JAXM Web Service, you have to implement the `onMessage()` method. You have to process the input SOAP message, generate an output SOAP message and return the output message.

Implementing a Web Service Method in .NET

To implement a Web service method in .NET, you have to define input parameters and return type.

These procedures are described in *Implementing a Web service method in Java* on page 246.

By default, PowerDesigner generates the C# or VB .NET Web Service class inside the .asmx file. If you want to generate the C# or VB .NET class in a separate file and use the CodeBehind mode for the .asmx file, you have to modify a generation option: in the Options tab of the Generation dialog box, set the value of Generate Web Service code in .asmx file to False.

You can preview the .asmx file code and the WSDL code from the Preview tab of the class property sheet.

Defining Web Service Method Extended Attributes

You can customize the WSDL generation using extended attributes. They allow you to modify input message name, output message name, SOAP operation style, port types to generate, SOAP action, Web method type, and so on.

1. Open the operation property sheet.

2. Click the WSDL attributes tab and modify extended attributes.

Operation Properties - GetQuote (getQuote)

General | Web Method | SOAP Input | SOAP Output | SOAP Fault | Parameters
Implementation | Mapping | WSDL attributes | JavaDoc | Notes | Extended Attributes

HTTP get port type

HTTP post port type

Input HTTP get message name: %Code%HttpGetIn

Input HTTP post message name: %Code%HttpPostIn

Input SOAP body parts:

Input SOAP body use: literal

Input SOAP message name: %Code%SoapIn

Output HTTP get message name: %Code%HttpGetOut

Output HTTP post message name: %Code%HttpPostOut

Output SOAP body parts:

Output SOAP body use: literal

Output SOAP message name: %Code%SoapOut

Port type: SOAP and HTTP

Return MIME type: text/xml

Return name: %Code%Result

SOAP action:

SOAP body namespace:

SOAP operation style: document

SOAP port type

Web method type: Request-Response

More >> | [List Icon] | OK | Cancel | Apply | Help

Defining SOAP Data Types of the WSDL Schema

Each Web method has an *input*, *output* and *fault* data type to be defined. A data type has a name and a schema definition.

For Reverse Engineered Web Services

Input, output and fault data types are set to the value found in the reversed WSDL schema. Data types that are not associated with any input, output, or fault are considered as shared

schema definitions and are available in the component. They are displayed in the WSDL Schema tab of the component property sheet.

For Newly Created Operations

Input and output data types are automatically set to a default value, and are synchronized with parameter changes. Default data type name and schema are defined in the WSDL extended model definition and can be customized. However once modified, a data type becomes user-defined and cannot be synchronized any more. Fault data types are always user-defined.

It is possible to reuse an existing data type defined in another operation. A check is available on components to make sure that no data type has different names inside the same component. You can use the Check Model feature to check the validity of your OOM at any time by selecting **Tools > Check Model**.

For more information on this check, see *Chapter 10, Checking an OOM* on page 313.

When *generating*, the WSDL schema is composed of the shared schema definitions from the component, and a computed combination of all SOAP input, output, and fault definitions from the operations.

You can type the SOAP input, SOAP output and SOAP fault data type names in the appropriate tabs in the operation property sheet. Each tab contains a box, and a text zone in which you can edit the data type definition from the WSDL schema.

Defining Web Service Component Instances

The deployment diagram is used with Web services to model the Web services deployment. This diagram is useful if you want to deploy a Web service into one or several servers, and if you want to know which Web service is deployed where, as deployment diagrams can display network addresses, access endpoints and access types.

A component instance defines the ports, the access type, and the access endpoint that is the full URL to invoke the Web service.

When the Web Service check box is selected in the property sheet of the component instance, it means that the component instance is an instance of a Web service component. A component instance that inherits from a component inherits its type: the type of the component is displayed in the property sheet of the component instance.

When the Web Service check box is selected, a Web Service tab and a WSDL tab automatically appear in the property sheet of the component instance.

For more information on the deployment diagram, see *Chapter 5, Building Implementation Diagrams* on page 209.

Web Service Tab of the Component Instance

The Web Service tab in the property sheet of the component instance includes the following properties:

Property	Description
Access point URL	Displays the full URL to invoke the Web service. It is a calculated value that uses the network address located in the node. You can also type your own URL by using the User-Defined tool to the right of the box. Once clicked, the URL can be overridden
WSDL URL	Indicates where the WSDL should be published on the web. You can type your own URL by using the User-Defined tool to the right of the box. Once clicked, the URL can be overridden
Use external WSDL	Indicates that the WSDL is published at a specific URL

When a WSDL is not user-defined, it is regenerated each time and can be displayed in the Preview tab of the component instance property sheet. An external WSDL has a user-defined WSDL text.

Access Point URL Examples

Here are some examples of the syntax used in .NET and Java:

For .NET, the default syntax is:

```
accesstype://machine_networkaddress:port/application_namespace/  
webservice_code.asmx
```

For example: <http://doc.sybase.com:8080/WebService1/StockQuote.asmx>.

For Java, the default syntax is:

```
accesstype://machine_networkaddress:port/application_namespace/  
webservice_code
```

For example: <http://doc.sybase.com/WebService1/StockQuote>.

Computed attributes AccessType and PortNumber for code generator & VBScript are computed from the access point URL. For example: http, https.

WSDL URL Examples

For .NET, the default syntax is:

```
accesstype://machine_networkaddress:port/application_namespace/  
Webservice_code.asmx?WSDL
```

For Java, the default syntax is:

```
accesstype://machine_networkaddress:port/application_namespace/  
wsdl_file
```

WSDL Tab of the Component Instance

The WSDL tab in the property sheet of the component instance includes the following properties:

Property	Description
Target namespace	URL linked to a method that ensures the uniqueness of the Web service and avoids conflicts with other Web services of the same name. By default, it is: <code>http://tempuri.org/</code> for .NET, and <code>urn:%Component.targetNamespace%</code> for Java
Import interface WSDL	When selected, means that the implementation WSDL imports the existing interface WSDL
Comment	Used as the description of the WSDL file during WSDL generation and WSDL publishing in UDDI
WSDL editor	You can also use a text zone below the Comment area to display the contents of the WSDL. When you click the User-Defined tool among the available tools, you make the contents user-defined. Once clicked, the contents can be overridden

Note: You can display some of the tabs of the property sheet of a component instance by right-clicking the component instance symbol in the diagram and selecting the appropriate tab from the contextual menu.

Using Node Properties

The node property sheet includes the following property, specific to Web services:

Property	Description
Network address	Address or machine name. For example: <code>doc.sybase.com</code> , or <code>123.456.78.9</code>

Since a machine can be used for several services and each service may have a different access type, port number and path, the machine Network address is only used as a default value. You can redefine the real URL of each component instance in the property sheet of the component instance at any time.

Generating Web Services for Java

You can generate client side or server side implementation classes, interfaces, deployment descriptor, JAR, WAR, or EAR from the Generate object language command in the Language menu.

Web services *server side* code generation consists in generating the following items:

- Generate Web service implementation classes and interfaces (Java class, Stateless Session Bean, Servlet, etc.)
- Generate Web services deployment descriptor for Java using the Web Service for J2EE (JSR109) specification. The deployment descriptor is an XML file that must be in every WAR archive, it is named WEB.xml by convention and contains information needed for deploying a Web service
- Generate interface WSDL and implementation WSDL files (WSDL files can be generated separately because they can be used for UDDI or client applications)

In general, once a Web service is deployed, the server is capable of generating an implementation WSDL.

Web services *client side* code generation consists in generating proxy classes.

PowerDesigner supports several Web service implementation types in Java:

- JAXM: <http://java.sun.com/xml/jaxm/index.html>
- JAX-RPC: <http://java.sun.com/xml/jaxrpc/index.html>
- Web Service for J2EE (JSR 109): <http://www.jcp.org/en/jsr/detail?id=109>
- AXIS RPC and EJB and Java Web Service (JWS): <http://ws.apache.org/axis/>

Generating JAXM Web Services

JAXM is a Java API for XML messaging that provides a standard way to send XML documents over the Internet from the Java platform.

If the Web service implementation type is JAXM, PowerDesigner uses the JAXM model for implementation. JAXM Web Service components provide the flexibility for handling complex message formats.

The JAXM Java class uses the `onMessage()` method to get the SOAP input message and return the output SOAP message. To generate correct WSDL, you have to define a Web Service method with the correct name, input message format and output message format but without implementation. The `onMessage()` method should not be defined as a Web Service method.

To Use JAXM, you can use the Java Web Services Developer Pack (JWSDP) 1.1 or higher from Sun or a Servlet container or J2EE server that supports JAXM. You can download JWSDP from <http://java.sun.com/webservices/>.

To compile JAXM Web service components, you need the `jaxm-api.jar`, `jaxp-api.jar` and `saaj-api.jar` files in your CLASSPATH environment variable. You can also define a JAVACLASSPATH variable in PowerDesigner to define the classpath specific to PowerDesigner, in this case the JAVACLASSPATH variable replaces the CLASSPATH environment variable

You need an application server or a Servlet container that supports JAXM. JWSDP ships with Apache Tomcat that supports JAXM.

1. Select Language > Generate Java Code.

2. Select a directory where you want to generate the code.
3. In the Tasks tab, select the command Java: Package J2EE application in an EAR file. This command will create a .WAR file and a .EAR file.
4. Click OK.

Generating JAX-RPC Web Services

JAX-RPC is a Java API for XML-based RPC (Remote Procedure Calling protocol). It facilitates RPC over the Internet allowing XML formatted parameters to be passed to remote services and allowing XML formatted values to be returned.

If the Web service implementation type is JAX-RPC, PowerDesigner uses the JAX-RPC model for implementation. JAX-RPC defines RPC type invocation for Web Services but it is limited to simple message formats. You can use very complex Objects/XML mapping.

Using the JAX-RPC model implies to:

- Generate the Web Service Java class and interface code
- Compile the Web Service Java class and interface
- Run a JAX-RPC tool to generate server side artifacts and client side proxy to handle the Web Service
- Package all the compiled code, WSDL and deployment descriptor in a .WAR file
- Deploy the .WAR file in a server that supports JAX-RPC

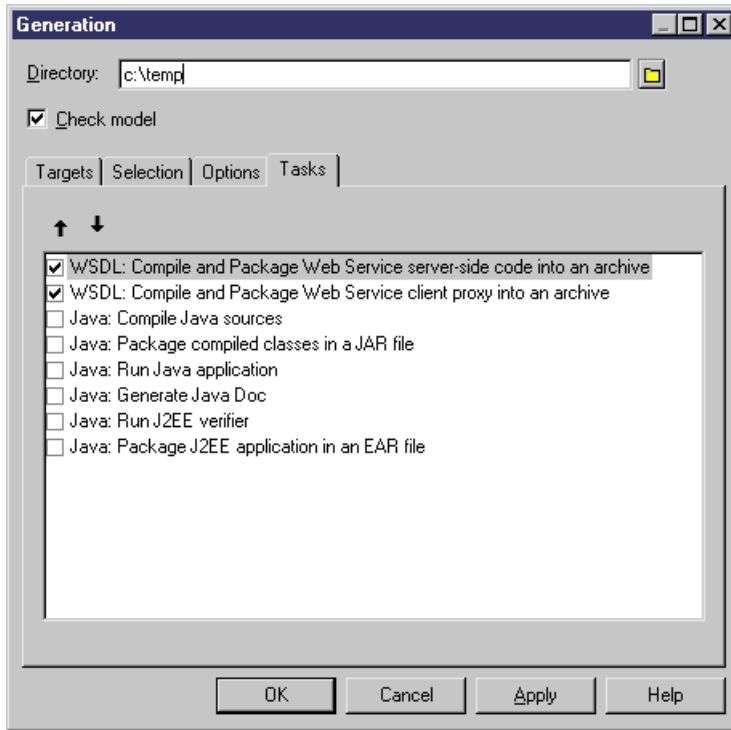

To Use JAX-RPC, you can use the Java Web Services Developer Pack (JWSDP) 1.1 or higher from Sun or other application servers that support the JAX-RPC model. You can download JWSDP from <http://java.sun.com/webservices/>.

To generate server side code and client proxy for JAX-RPC, if you use JWSDP, you can use the `wscmpile.bat` tool. For other JAX-RPC compatible implementations, please refer to the documentation. To invoke the `wscmpile.bat` tool from PowerDesigner, you have to define an environment variable `WSCOMPILE` in the Variables category located in the General Options windows (**Tools > General Options**). The `WSCOMPILE` variable should indicate the full path of the `wscmpile.bat` file. To run `wscmpile.bat`, the `jaxrpc-api.jar` file must be in your `CLASSPATH` environment variable. You can also define a `JAVACLASSPATH` variable in PowerDesigner to define the classpath specific to PowerDesigner, in this case the `JAVACLASSPATH` variable replaces the `CLASSPATH` environment variable

To deploy JAX-RPC Web service components, you need an application server or a Servlet container that supports JAX-RPC. JWSDP ships with Apache Tomcat that supports JAX-RPC

1. Select **Language > Generate Java Code**.
2. Select a directory where you want to generate the code.
3. In the **Tasks** tab, to generate server side code, select the command WSDL: Compile and Package Web Service Server-Side Code into an archive. To generate client proxy, select the command WSDL: Compile and Package Web Service Client Proxy into an archive.

These commands will compile the Java classes generated by PowerDesigner, run the WSCOMPILE tool and create a .WAR file.

4. Click **OK**.

Generating Stateless Session Bean Web Services

PowerDesigner supports the Web Services for J2EE specification that defines the programming model and runtime architecture for implementing Web services.

In Java, Web services may be implemented either through JAX-RPC endpoints or EJB stateless session bean components. Both of these implementations expose their Web methods through a service endpoint interface (SEI).

JAX-RPC endpoints are considered as Web components, they are represented as *servlets* in the OOM and are packaged into a WAR, while EJB *stateless session beans* are packaged into an EJB JAR. In both cases, WSDL files, and the required deployment descriptors should be included in the WEB-INF or META-INF directories. You can refer to chapters 5 and 7 of the Web Services for J2EE specification for more information.

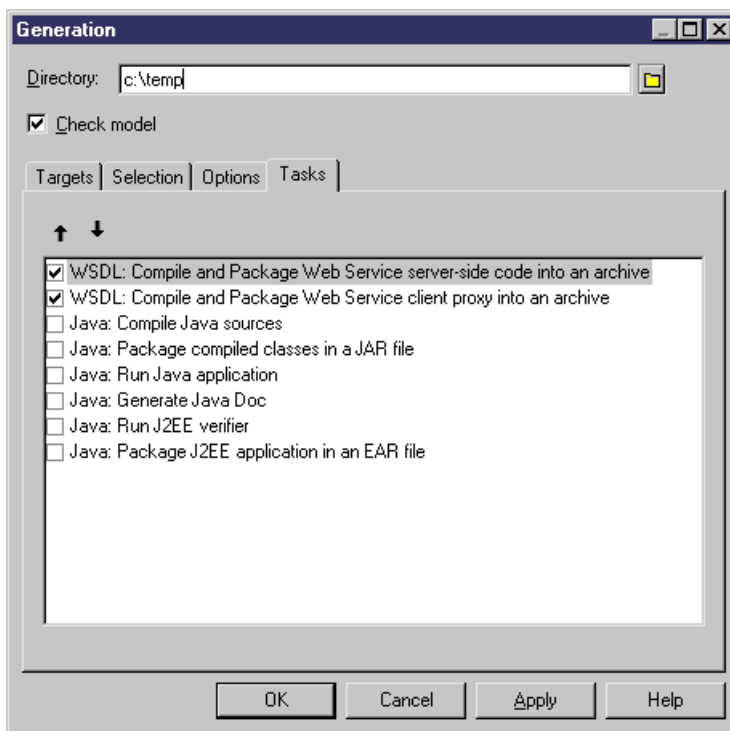

If the Web service implementation type is Stateless Session Bean, PowerDesigner uses Web Services for J2EE specification for implementation.

Developing Stateless Session Bean as Web Service is similar to JAX-RPC: you use a Bean class instead of a normal Java class. As for JAX-RPC, it is limited to simple message formats.

For more information on JAX-RPC, see *Generating JAX-RPC Web services* on page 257.

1. Select **Language > Generate Java Code**.
2. Select a directory where you want to generate the code.
3. In the Tasks tab, to generate server side code, select the command WSDL: Compile and Package Web Service Server-Side Code into an archive. To generate client proxy, select the command WSDL: Compile and Package Web Service Client Proxy into an archive.

These commands will compile the Java classes generated by PowerDesigner, run the WSCOMPILE tool and create a .WAR file.

4. Click OK.

Generating AXIS RPC Web Services

If the Web service implementation type is AXIS RPC, PowerDesigner uses a Java class for implementation and Apache Axis for deployment.

The supported provider type is Java:RPC. The supported provider styles are RPC, document and wrapped. If the provider style is <Default>, PowerDesigner will automatically select the

best provider style. To select the provider style, you can change the AxisProviderStyle extended attribute of the Web service component.

To customize Axis deployment descriptor generation, you can change several Axis specific extended attributes in the Web service component property sheet.

A deploy.wsdd and an undeploy.wsdd are generated from the model or the package that contains Web service components. A single deploy.wsdd and undeploy.wsdd files are generated for all Web service components of the model or package.

1. Select **Language > Generate Java Code**.
2. Select a directory where you want to generate the code.
3. [optional] Click the **Selection** tab and select the objects that you want to generate on the various sub-tabs. By default, all objects are generated.
4. [optional] Click the **Options** tab and select any appropriate generation options.
5. [optional] Click the **Tasks** tab and select any appropriate tasks to perform during generation
6. Click **OK** to begin generation.

A progress box is displayed during generation. When the generation is complete PowerDesigner displays a list of the generated files that you can edit. The results are also displayed on the **Generation** tab of the Output window.

Generating AXIS EJB Web Services

If the Web service implementation type is AXIS EJB, PowerDesigner uses a Stateless Session Bean for the implementation, an application server for EJB deployment and Apache Axis for exposing the EJB as a Web service.

To customize the generation of the Axis deployment descriptor, you can change several Axis specific extended attributes in the Web service component properties.

A deploy.wsdd and an undeploy.wsdd are generated from the model or the package that contains Web service components. A single deploy.wsdd and undeploy.wsdd files are generated for all Web service components of the model or package.

To expose a Stateless Session Bean as Web service using Axis, you need to:

- Generate the EJB code
- Compile and package the EJB
- Deploy the EJB in a J2EE server
- Expose the EJB as a Web Service using Axis

1. Select **Language > Generate Java Code**.
2. Select a directory where you want to generate the code.
3. In the options tab, you can modify generation options and deployment options.

4. In the Tasks tab, you can select the commands in the following order: Package J2EE application in an EAR file, Deploy J2EE application, Expose EJB as Web Services.

Generating Java Web Services (JWS)

If the Web service implementation type is Java Web Service (JWS), PowerDesigner uses a Java class for implementation. The Java class will have the .jws extension.

To deploy the Java class, you can simply copy the .jws file to the server that supports Java Web Service format. For example, for Apache Axis, you can copy the .jws file to the directory webapps\axis.

Testing Web Services for Java

To test a Java Web Service, there are several methods:

- Send SOAP message. You can write a Java program to send SOAP message to a Web Service and process the returned output SOAP message using the SAAJ API
- Use Dynamic Invocation. You can use the Dynamic Invocation method defined by JAX-RPC
- Use Dynamic Proxy. You can use the Dynamic Proxy method defined by JAX-RPC
- Use Client Proxy. You can use a client proxy to invoke a Web Service easily. If you use the JWSDP, you can use the wscompile.bat tool to generate a client proxy. If you use Apache Axis, you can use the java.org.apache.axis.wsdl.WSDL2Java Java class

Generating Web Services for .NET

The following items are generated in .NET languages (C# and VB.NET):

- An implementation class (C# or VB.NET) with special super class and WebMethod property for the methods. If you disable the Generate Web Service C# code in .asmx file option, a C# or VB .NET class will also be generated for each Web Service
- A .ASM file

Note

It is not necessary to define the super class (also known as WebService) for the Web service classes; if the WebService super class is not defined, the code generator adds it to the code.

When generating the server side code, you can use the following default options and tasks that help you automatically start generating with pre-defined characteristics.

Defining Web Services Generation Options in .NET

You can select Web services generation options available for .NET languages by starting the Generate object language command in the Language menu.

C# Generation Options

The following options are available from the Options tab in the Generation dialog box for C#:

Option	Description
Generate C# web Service code in .ASMX	Generates the C# code in the .ASMX file

VB.NET Generation Options

The following options are available from the Options tab in the Generation dialog box for VB.NET:

Option	Description
Generate VB.NET Web service code in .ASMX	Generates the Visual Basic.NET code in the .ASMX file

Defining Web Service Generation Tasks in .NET

You can select Web services generation tasks available for .NET languages by starting selecting **Language > Generate object language**.

The following tasks are available from the Tasks tab in the Generation dialog box for C# and VB.NET:

Option	Description
Compile source files	Compiles the generated code
Generate Web service proxy code	Generates the Web Service proxy class for a Web Service component instance. You need to define a component instance for the Web Service deployment URL
Open the solution in Visual Studio .NET	If you selected the Generate Visual Studio .NET project files option, this task allows to open the solution in the Visual Studio .NET development environment

Generating Web Services in .NET

The deployment of a Web service consists in copying the generated implementation class and .ASMX file into the directory of the web server virtual folder.

The .ASMX is an ASP.NET file, it contains the code of the C# or VB.NET Web service class.

1. Select **Language > Generate C# Code** or **Generate VB .NET Code**.
2. Select the generation directory. You can select a Microsoft Internet Information Server (IIS) directory for generation, for example, C:\Inetpub\wwwroot\StockQuote. If you have defined you Web Services inside a package, you can generate the Web Services code in the C:\Inetpub\wwwroot directory. Each package will create a subdirectory.
3. Set the Generate Web Service C# code in .asmx file option to false in the Options tab if you want to generate the C# or VB .NET class outside a .asmx file.
4. Select the Compile C# code or VB .NET code command in the Tasks tab if you generate the C# or VB .NET Web Service class outside a .asmx file.
5. Click OK.

The code generation process creates a subdirectory under wwwroot using the package name, and creates a <WebServiceName>.ASMX file within the subdirectory.

Generating a .NET Proxy Class for a Web Service

PowerDesigner can also generate a client proxy class to simplify the invocation of the Web Service. To generate the client proxy class, PowerDesigner uses the wsdl.exe program that comes with Visual Studio .NET. You have to define a WSDL variable to indicate where the wsdl.exe program is located.

Define the WSDL Variable

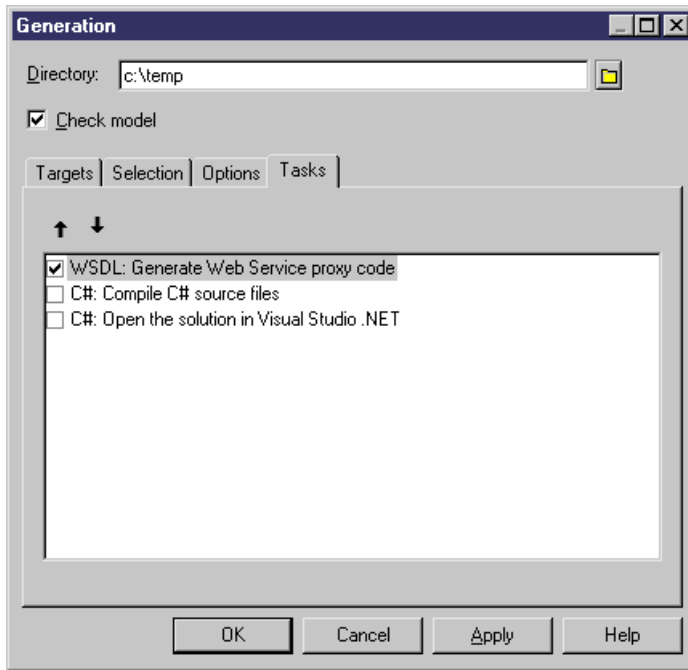

To define a WSDL variable:

1. Select **Tools > General Options**.
2. Select the Variables category.
3. Add a WSDL variable in the Name column.
4. Browse for the wsdl.exe file in the Value column.
5. Click OK.

Generate the Client Proxy Classes

To generate the client proxy classes:

1. Select **Language > Generate C# Code** or **Generate VB .NET Code**.
2. Open the Tasks tab.
3. Select the command WSDL: Generate Web Service proxy code.

4. Click OK.

Deploying Web Services in .NET

To deploy and test a Web Service for .NET, you have to install Microsoft Internet Information Server (IIS). In the machine where you install IIS, you also have to install the .NET Framework. You can download .NET Framework or .NET Framework SDK from the Microsoft web site.

To deploy the generated Web Service code, you simply copy the .asmx file and the C# or VB .NET class files under the IIS directory `C:\Inetpub\wwwroot<PackageName>`, where `<PackageName>` is the name of the package. For example: `C:\Inetpub\wwwroot\StockQuote`.

Testing Web Services for .NET

To test the Web Service, you have to enter the URL of the Web Service in the browser: `http://[HostName]/[PackageName]/[ServiceName].asmx`. For example: `http://localhost/StockQuote/StockQuote.asmx`.

The IIS Web server will generate a testing tab to let you test the deployed Web Service if the input parameters and the return value use simple data types.

To test Web Services with complex data types, you have to create a testing program using Web Service proxy or use a tool to send a SOAP message to the Web Service.

Generating Web Services for Sybase WorkSpace

Sybase WorkSpace provides an integrated development environment to develop, test and deploy Web services. PowerDesigner allows you to generate Java and EJB Web services and use the Sybase WorkSpace utilities to fine-tune their implementation.

You can design your Web services using the standard PowerDesigner environment or using the PowerDesigner Eclipse plugin that runs in the WorkSpace environment (see *Chapter 14, Working with the PowerDesigner Plugin for Eclipse* in the *Core Features Guide*).

PowerDesigner helps you to quickly:

- Create a Web service with the correct implementation class and extended model definition
- Define the Java class package
- Generate the Web service and open it in the Workspace Java Service Editor

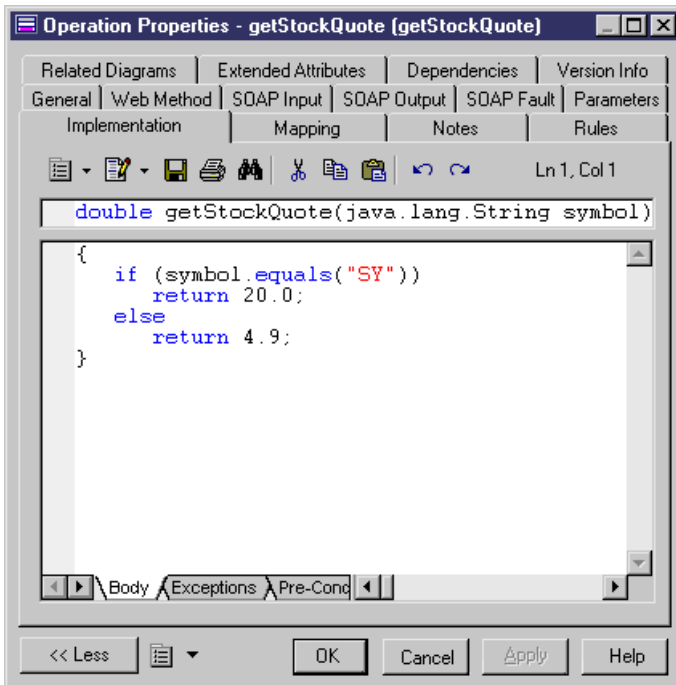

Creating a Java or EJB Web Service for Sybase WorkSpace

PowerDesigner provides full support for creating a Java Web service for Sybase WorkSpace.

1. Select **File > New Model** to open the New Model dialog, and select Object Oriented Model in the **Model Type** list.
2. Select Java in the **Object language** list and select Class diagram in the **Diagram** list.
3. Click the **Select Extensions** button, click the **IDE** sub-tab, select the Sybase WorkSpace xem, and click **OK** to return to the New Model dialog.
4. Click **OK** to create the OOM.
5. Select **Tools > Create Web Service Component** to open the Web Service Wizard.
6. Type a name and a code for the component and click **Next**.
7. Select Implementation in the **Web Service Type** list and select one of the following in the **Component Type** list:
 - Java Web Service (JWS)
 - Axis EJB (Stateless Session Bean)
8. Click **Next**, select a Web service implementation class, and then click **Finish**.

The Web service component is created together with the implementation class and the corresponding Web method.

9. Double-click the implementation class in the diagram and open the **Operations** tab in the class property sheet.
10. Double-click the WebMethod created by default. The **Web Service Method** check box is selected. You can rename the operation if necessary.
11. Click the **Implementation** tab and enter the implementation of the Web service:

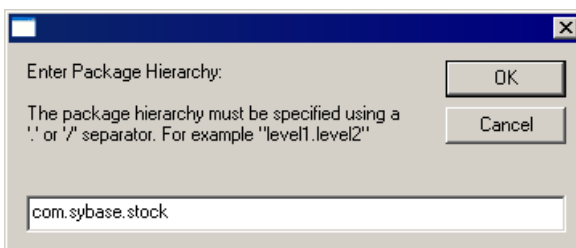

12. Click **OK** in each of the dialog boxes.

You can preview the code that will be generated for the Web service by clicking the **Preview** tab of the associated class or component. You can customize the Web service by editing the properties of the component.

Defining the Java Class Package

When you create a Web service using the Web Service Wizard, the Java class and the Web service component are both created at the model level. You can, if necessary, define a package name for your Java class and component.

1. Right-click the model in the Browser, and select **Add Package Hierarchy** from the contextual menu.

2. Enter the appropriate package hierarchy and click **OK** to create it in the model.

Generating the Java or EJB Web Service for Sybase WorkSpace

PowerDesigner can generate all the files that you need to work with to define the Web service in the Workspace Java Service Editor.

1. Select **Language > Generate Java code** to open the Generation dialog.
2. Enter a destination directory to which to generate the files.
3. Ensure that the Sybase WorkSpace IDE is selected on the **Targets** tab.
4. Click **OK** to generate the following files:
 - A `svc_java` or `svc_ejb` file that defines the Web service
 - A `.java` file for the implementation of the Web service
 - A `.project` file for creating a Java project if it does not exist
 - A `.classpath` file for defining Java libraries in a Java project

When you generate using the PowerDesigner Eclipse plugin an Eclipse project will be created or, if you are generating to an existing project, the project will be refreshed to show the new files.

5. In Workspace, right-click the `.svc_java` file in the Navigator window and select **Open with > Java Service Editor**.
6. Click the **Interface** sub-tab and continue with the implementation of the service.

For more information on the Java Service Editor, see your Sybase Workspace documentation.

Understanding the .svc_java or .svc_ejb File

PowerDesigner generates a `svc_java` or `svc_ejb` file for each Web service.

Each file contains the following fields:

Field	Component property
<code>serviceName</code>	Web service component code
<code>serviceComment</code>	Web service component comment
<code>projectName</code>	[<code>svc_java</code> only] Last directory name of the generation full path
<code>projectPath</code>	[<code>svc_ejb</code> only] The project directory and folder name
<code>serviceFilename</code>	% <code>serviceName</code> %. <code>svc_java</code>
<code>authorName</code>	Web service component modifier name
<code>dateCreated</code>	Generation date and time in the format: Mmm dd, yyyy hh:mm:ss AM/PM
<code>ejbFullName</code>	[<code>svc_ejb</code> only] <PackageCode>.<ComponentCode>

Field	Component property
operationName	Web method code
operationComment	Web method comment
static	[svc_java only] Use "METHOD_TYPE_STATIC" if the web method is static
inputMessage	Input message name
outputMessage	Output message name
returnType	Web operation return type
parameterName	Operation parameter code
parameterComment	Operation parameter comment
dataType	Operation parameter data type
javaServiceParamType	[svc_java only] Web operation parameter type
classFullPath	%projectName %/ %qualifiedClassName%
qualifiedClassName	Fully qualified Java class file name
endpointName	[svc_ejb only] End point name
connectionName	[svc_ejb only] Application server connection profile name.
EJBComponentURI	[svc_ejb only] EJB component URI
jndiProviderURL	[svc_ejb only] JNDI provider URL
initialContextFactory	[svc_ejb only] Initial context factory class name
jndiName	[svc_ejb only] EJB JNDI name
clientJAR	[svc_ejb only] Client JAR file path
ejbRemoteInterface	[svc_ejb only] EJB remote interface fully qualified name
ejbHomeInterface	[svc_ejb only] EJB home interface fully qualified name

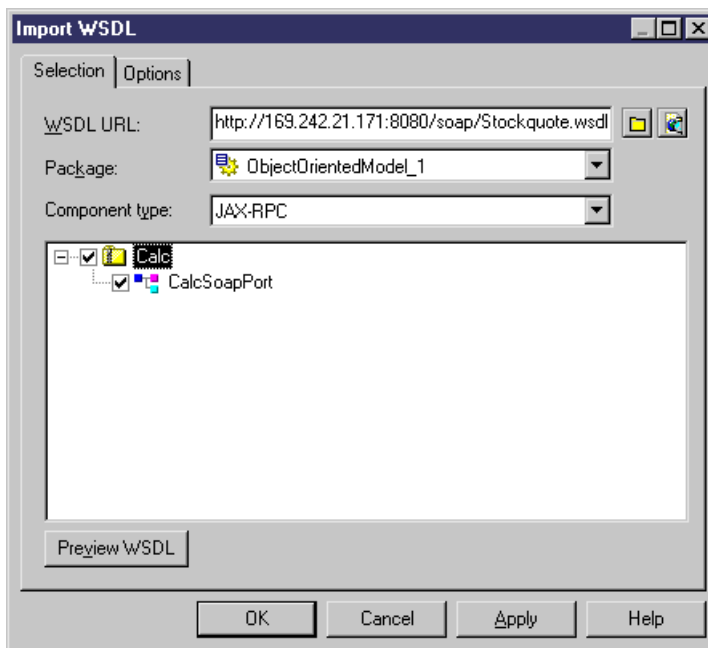

Importing WSDL Files

PowerDesigner can import WSDL files for .NET and Java.

1. Select **Language > Import WSDL** to open the Import WSDL dialog.
2. On the **Selection** tab, complete the following fields:

Item	Description
WSDL URL	Indicates the location of the WSDL file. You can complete this field by: <ul style="list-style-type: none"> • Entering the location directly in the field • Clicking the Browse File tool to browse on your local file system • Clicking the Browse UDDI tool to search on a UDDI server (see <i>Browsing WSDL Files from UDDI</i> on page 270)
Package	Specifies the package and namespace where the component and the Web service class will be created.
Component type	[Java only] Specifies the type of the component to create.

3. Select the Web services and port types you want to import.

Each Web service selected will be imported as a component and an implementation class. Each port type selected in a selected Web service generates an interface.

4. [optional] Click the **Preview WSDL** button to preview the WSDL and the unique key used to locate the UDDI.
5. [optional] Click the **Options** tab, which allows you to specify in which diagrams PowerDesigner should create the symbols for the imported objects. Deselecting an option will suppress the creation of a symbol, but the object will still be imported.
6. Click **OK** to begin the import.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog opens to allow you to select how the imported objects will be merged with your model

For detailed information about merging models, see *Chapter 7, Comparing and Merging Models* in the *Core Features Guide*.

Each Web service selected will be imported as a component and an implementation class. Each port type selected in a selected Web service generates an interface.

Note: If the WSDL contains a section prefixed with <!-- service -->, a component instance is created. This section is displayed in the WSDL tab in the property sheet of the component instance.

Browsing WSDL Files from UDDI

PowerDesigner provides an interface for browsing for a WSDL directly on a UDDI server.

1. Click the **Browse UDDI** tool to the right of the WSDL URL field on the Selection tab of the Import WSDL dialog.

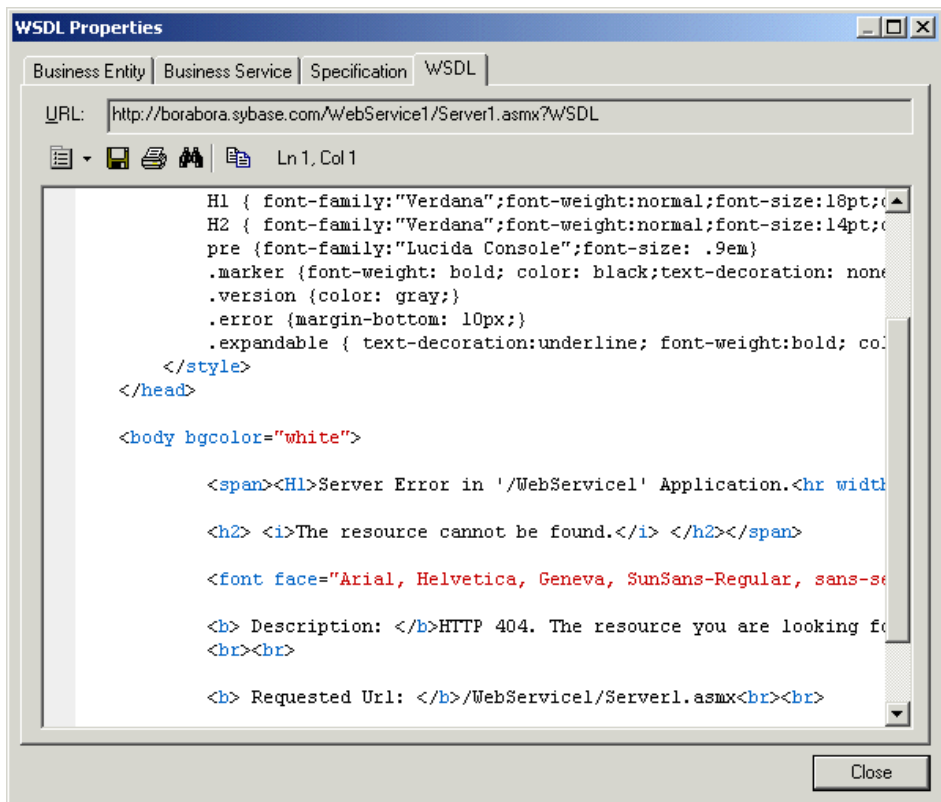

2. Complete the following fields to specify your search criteria:

Item	Description
UDDI operator URL	Choose from a list of default UDDI operator URLs, or enter your own URL.
UDDI version	Specify the correct UDDI version for the URL.
Search for	Specify the name of the item to search for.
Search in	Specify whether to search on the business entity (company name), Web service name, or WSDL name.

- Click the **Search** button.

The result is displayed in the Search Result window.

- [optional] Click the **Preview WSDL** button to open the WSDL property sheet, which contains various tabs allowing you to view information about the business entity and service, the specification and the WSDL code:

- Click **Close** to return to the Browse UDDI dialog.
- Click **OK** to return to the Import WSDL dialog to complete the import.

PART II

Working with OOMs

The chapters in this part provide information about PowerDesigner features that allow you to customize, check, generate from, and reverse-engineer to your object-oriented models .

CHAPTER 7 Generating and Reverse Engineering OO Source Files

PowerDesigner can generate and reverse engineer source files from and to an OOM.

Generating OO Source Files from an OOM

By default, PowerDesigner supports the generation of the following types of objects for the languages supported by the OOM:

Object language	What is generated
Analysis	No files generated as this language is mainly used for modeling purpose
C#	.CS definition files
C++	C++ definition files (.h and .cpp)
IDL-CORBA	IDL-CORBA definition files
Java	Java files from classes and interfaces of the model. Includes support of EJB and J2EE
PowerBuilder	.PBL application or .SRU files from classes of the model
Visual Basic.Net	.VB files
XML-DTD	.DTD files
XML-Schema	.XSD files. Includes standard XML language properties

The PowerDesigner generation system is extremely customizable through the use of extended model definitions, profiles, and generation templates.

For detailed information about customizing the generation of your code, see *Customizing and Extending PowerDesigner*.

Generating Source Files

PowerDesigner provides a standard interface for generating source files for all the supported OO languages. For details of language-specific options and generation tasks, see the appropriate language chapter.

1. Select **Language > Generate language Code** to open the Generation dialog box:

2. Enter a directory in which to generate the files, and specify whether you want to perform a model check. For more information about checking your model, see *Chapter 10, Checking an OOM* on page 313.
3. [optional] Select any additional targets to generate for. These additional targets are defined by the extended model definitions that are attached to your model. For more information, see *Working with generation targets* on page 278.
4. [optional] Click the Selection tab and specify the objects that you want to generate from. By default, all objects are generated, and PowerDesigner remembers for any subsequent generation the changes you make.

- [optional] Click the Options tab and set any necessary generation options. For more information about these options, see the appropriate language chapter.

For information about editing the options that appear on this tab, see "Generation category" in the Resource Files and the Public Metamodel chapter of *Customizing and Extending PowerDesigner*.

- [optional] Click the Generated Files tab and specify which files will be generated. By default, all files are generated, and PowerDesigner remembers for any subsequent generation the changes you make.

For information about customizing the files that will be generated, see "Templates and Generated Files" in the Extending Your Models with Profiles chapter of *Customizing and Extending PowerDesigner*.

- [optional] Click the Tasks tab and specify any additional generation tasks to perform. For more information about these tasks, see the appropriate language chapter.

For information about adding your own generation tasks, see "Generation category" in the Resource Files and the Public Metamodel chapter of *Customizing and Extending PowerDesigner*.

- Click OK to begin generation.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation tab of the Output window, located in the bottom part of the main window.

All files are generated in the destination directory.

Working with Generation Targets

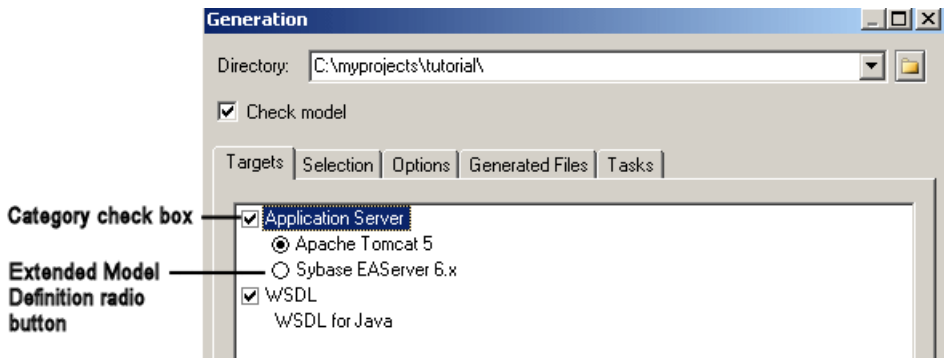

The Targets tab of the Generation dialog box allows you to specify additional generation targets, which are defined by extended model definition (.XEMs) attached to your model.

PowerDesigner provides many XEMs, which are used to extend the object language for use with a particular server, framework, etc. and you can also create your own. XEMs can be attached to your model:

- at the moment of creation, via the Extended Model Definitions tab of the New dialog box
- at any time, via the **Model > Extended Model Definitions** menu item

For more information about attaching XEMs to your model, see "Extended Model Definitions" in the Models chapter of the *Core Features Guide*.

The Generation dialog Targets tab groups targets by category. For each category, it is only possible to select one extended model definition at a time.

For more information about editing and creating XEMs, see "Extended Model Definitions" in the Resource Files and the Public Metamodel chapter of *Customizing and Extending PowerDesigner*.

Defining the Source Code Package

For those languages that support the concept of packages and/or namespaces, classes must be generated in packages that are used as qualifying namespace. You can define these qualifying packages one by one in the model as necessary, or insert a base structure automatically via the Add Package Hierarchy command.

1. Right-click the Model in the Browser, and select Add Package Hierarchy from the contextual menu.

2. Enter a package hierarchy in the text field, using periods or slashes to separate the packages. For example:

```
com.mycompany.myproduct.oom
```

or

```
com/mycompany/myproduct/oom
```

The corresponding package hierarchy will be created in the Browser. All diagrams and objects (except global objects) existing in the model will be moved to the lowest level package of the hierarchy.

Enabling Trace Mode in Preview Tabs

You can display the generation templates that generate code from the Preview page in object property sheets, provided the *Enable Trace Mode* check box is selected in the object language, or extended model definition editors.

For more information on the trace mode property, see "Resource File Properties" in the Resource Files and the Public Metamodel chapter of the *Customizing and Extending PowerDesigner* manual.

Reverse Engineering OO Source Files into an OOM

Reverse engineering is the process of extracting data or source code from a file and using it to build or update an OOM. You can reverse engineer objects to a new model, or to an existing model.

You can reverse the following types of files into an OOM:

- Java
- IDL
- PowerBuilder
- XML - PowerDesigner uses a parser developed by the Apache Software Foundation (<http://www.apache.org>).
- C#
- VB
- VB.NET

Inner Classifiers

When you reverse a language containing one or more inner classifiers (see *Composite and Inner Classifiers* on page 43) into an OOM, one class is created for the outer class, and one class is created for each of the inner classifiers, and an inner link is created between each inner classifier and the outer class.

Symbol Creation

If you select the Create Symbols reverse option, the layout of the symbols in the diagram is automatically arranged. When reverse engineering a large number of objects with complex interactions, auto-layout may create synonyms of objects to improve the diagram readability.

Reverse Engineering OO Files into a New OOM

You can reverse engineer object language files to create a new OOM.

1. Select **File > Reverse Engineer > Object Language** to open the New Object-Oriented Model dialog box.
2. Select an object language in the list and click the Share radio button.
3. [optional] Click the **Select Extensions** tab, and select the extended model definitions you want to attach to the new model.

For more information on extended model definitions, see "Extended Model Definitions" in the Resource Files and the Public Metamodel chapter of *Customizing and Extending PowerDesigner*.

4. Click **OK** to go to the appropriate, language-specific Reverse Engineering window. For detailed information about this window for your language see the appropriate language chapter.
5. Select the files that you want to reverse and the options to set, and then click **OK** to start reverse engineering.

A progress box is displayed. The classes are added to your model

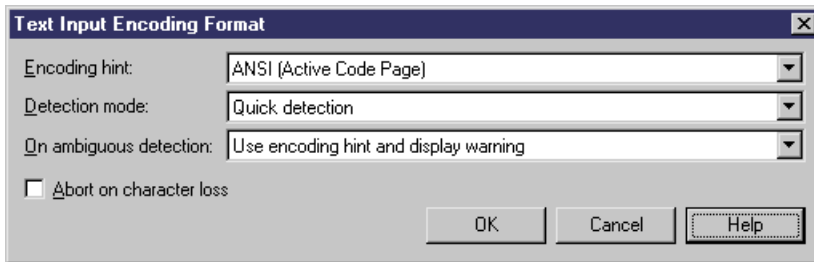

Note: This product includes XML4C 3.0.1 software developed by the Apache Software Foundation (<http://www.apache.org>)

Copyright (c) 1999 The Apache Software Foundation. All rights reserved. THE XML4C 3.0.1 SOFTWARE ("SOFTWARE") IS PROVIDED ``AS IS" AND ANY EXPRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE APACHE SOFTWARE FOUNDATION OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Reverse Engineering Encoding Format

If the applications you want to reverse contain source files written with Unicode or MBCS (Multibyte character set), you should use the encoding parameters provided to you in the File Encoding box.

If you want to change these parameters because you know which encoding is used within the sources, you can select the appropriate encoding parameter by clicking the Ellipsis button beside the File Encoding box. This opens the Text Input Encoding Format dialog box in which you can select the encoding format of your choice.

The Text Input Encoding Format dialog box includes the following options:

Option	Description
Encoding hint	Encoding format to be used as hint when reversing the file
Detection mode	Indicates whether text encoding detection is to be attempted and specifies how much of each file should be analyzed. You can select from the following options: <ul style="list-style-type: none"> No detection - Turns off the detection feature. Select this option when you know what the encoding format is Quick detection - Analyzes a small buffer to perform detection. Select this option when you think that the encoding format will be easy to detect Full detection - Analyzes the whole file to perform detection. Select this option when you think that the number of characters that determine the encoding format is very small
On ambiguous detection	Specifies what action should be taken in case of ambiguity. You can select from the following options: <ul style="list-style-type: none"> Use encoding hint and display warning - the encoding hint is used and a warning message is displayed in the Reverse tab of the Output window Use encoding hint - uses the encoding format selected in the Encoding Hint box, if possible. No warning message is displayed Use detected encoding - Uses the encoding format detected by PowerDesigner
Abort on character loss	Allows you to stop reverse engineering if characters cannot be identified and are to be lost in current encoding

Here is an example on how to read encoding formats from the list:

ASCII		
OEM		
UTF-8	—————>	No Byte-Order-Mark in the header
UTF-8 (with signature)		
Unicode		
Unicode (with signature)	—————>	There must be a Byte-Order-Mark in the header for the file to be valid
Unicode big endian		
Unicode big endian (with signature)		
ANSI (Active Code Page)		

Reverse Engineering into an Existing OOM

You can reverse engineer source files to add objects to an existing OOM.

1. Select **Language > Reverse Engineer** to display Reverse Engineering dialog box.
2. Select to reverse engineer files or directories from the Reverse Engineering list.
3. Click the add button in the Selection tab to display a standard Open dialog box.
4. Select the files or directory to reverse engineer and click Open.
5. Click OK to begin reverse engineering.

A message in the Output window indicates that the specified file is fully reverse engineered and the Merge Models window opens.

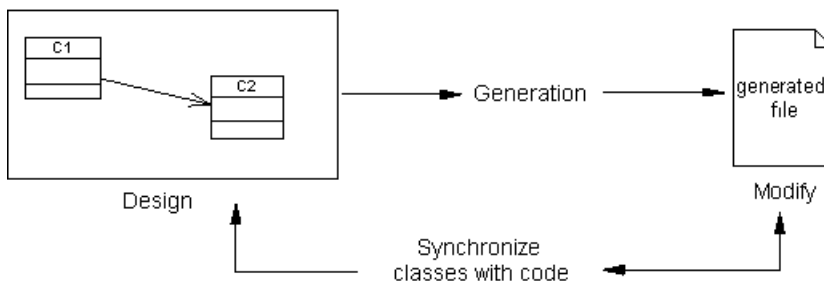

6. Review the objects that you will be importing, and the changes that they will make to the model.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

7. Click OK to merge the selected changes into your model.

Synchronizing a Model with Generated Files

You can design your system in PowerDesigner, use the generation process, then visualize and modify the generated file in your code editor, synchronize the classifiers with the source code and then go back to the model. With this feature, you can modify the generated file and reverse in the same generated file.

The synchronization launches a reverse engineering dialog box, pre-selects option, and fills the list of classifiers with the classifiers selected in the class diagram.

You can then easily locate the files that should be taken into account for synchronization. If there is no classifier selected, the reverse feature pre-selects directories and adds the current directory to the list.

1. Select **Language > Synchronize with generated files** to display the Reverse dialog box.

The Selection tab is displayed.

2. Select to reverse engineer files or directories from the Reverse Engineering list.
3. Click the Add button to open the Browse for Folder dialog box.
4. Select the appropriate directory, and click OK to open the Reverse Java dialog box you need.
5. Click OK to begin synchronization.

A progress box is displayed, followed by the Merge Models dialog box.

Note: The Merge Models dialog box shows the From Model (source directory) in the left pane, and the To Model (current model) in the right pane. You can expand the nodes in the To Model pane to verify that the merge actions selected correspond to what you want to perform.

6. Review the objects that you will be importing, and the changes that they will make to the model, and then click OK.

The Reverse tab of the Output window displays the changes which occurred during synchronization and the diagram window displays the synchronized model.

CHAPTER 8 **Generating Other Models from an OOM**

You can generate the following types of models from an OOM:

- CDM - to translate OOM classes into CDM entities. You will then be able to further refine your model and eventually generate a Physical Data Model (PDM) from the CDM.
- PDM – to translate the design of your system to your database. This allows you to model the objects in the world they live in and to automate the translation to database tables and columns.
- OOM – to transform an analytical OOM (designed with the Analysis object language) to implementation OOMs designed for Java, C#, and any other of the object languages supported by PowerDesigner.
- XSM – to generate a message format from your class structure.

1. Select Tools, and then one of the following to open the appropriate Model Generation Options Window:

- Generate Conceptual Data Model... Ctrl+Shift+C
- Generate Physical Data Model... Ctrl+Shift+P
- Generate Object-Oriented Model... Ctrl+Shift+O
- Generate XML Model... Ctrl+Shift+M

2. On the General tab, select a radio button to generate a new or update an existing model, and complete the appropriate options.

3. [optional] Click the Detail tab and set any appropriate options. We recommend that you select the Check model checkbox to check the model for errors and warnings before generation.

4. [optional] Click the Target Models tab and specify the target models for any generated shortcuts.

5. [optional] Click the Selection tab and select or deselect objects to generate.

6. Click OK to begin generation.

Note: For detailed information about the options available on the various tabs of the Generation window, see *Chapter 10, Generating Models and Model Objects* in the *Core Features Guide*.

Mapping OOM Objects to other Model Objects

The following table details how OOM objects are generated to other models:

OOM	CDM	PDM	XSM
Domain	Domain	Domain	Simple Type
Class (Persistent and Generate check boxes selected)	Entity	Table	Element
Abstract class	Entity	Table	Complex type
Attribute (Persistent check box selected)	Attribute	Column	Attribute or element (see generation options)
Identifier	Identifier	Identifier	Key
Composition	-	-	New level in the element hierarchy
Operation with <<storedProcedure>> stereotype (parent class generated as a table)	-	Stored procedure attached to the table, with the operation body as a body in the procedure definition.	-
Operation with <<storedFunction>> stereotype (parent class generated as a table)	-	Stored function attached to the table, with the operation body as a body in the function definition.	-
Association	Relationship or association	Reference or table	KeyRef constraints
Association class	Entity/relationship notation: entity with two associations. Merise notation: association, and two association links	A table and two associations between the end points of the association class	-
Dependency	-	-	-
Realization	-	-	-

OOM	CDM	PDM	XSM
Generalization	Inheritance	Reference	Complex type derivation (XSD) or attribute migration to child element (DTD)

Generating from Classes

For a class to become a table you need to select the Persistent check box and define a type of generation in the Generation list in the Detail tab of the class property sheet.

The cardinality of a class becomes the number of records of a table.

Generating from Associations

If the association has a many-to-many multiplicity: both roles of the association have the * sign selected in their multiplicity lists, the association is translated into a table in the generated PDM. If it has any other multiplicity, the association becomes a reference.

A role name becomes a migrated foreign key after PDM generation.

Managing Object Persistence During OOM to CDM Generation

Developers tend to use object-oriented programming languages like Java, to develop business objects and components. Eventually, these objects can be represented in a conceptual data model prior to being stored in a database. A problem arises because object codes in object-oriented programming languages are often different than codes used in a CDM.

You can define persistent codes to bypass this impedance-mismatch.

Defining Object Persistence in the OOM

Persistent codes are codes defined for OOM classes and attributes that are used during OOM to CDM generation. They also facilitate round-trip engineering by allowing you to recover object codes from the conceptual data model.

All persistent classes are generated as entities. If you set the class generation mode (in the Persistent group box in the Detail tab of the class property sheet) to "Migrate columns", the Generated check box in the generated entity property sheet is cleared by default.

You can also define persistent data types for class attributes and domains. For data type persistence management, you have to take into account the following parameters:

- The data type is *simple*, based on standard OOM data types. If the data type is persistent, generation keeps persistent data type in the target model. Otherwise data type is converted to standard data type in the target model

- The data type is *complex*, based on a classifier. If the data type is persistent, you can define different generation options according to what you want to have in the target model and to the attribute multiplicity

Managing Complex Data Type Persistence

In the following example, both classes are defined as persistent.

Class Customer contains an attribute address with a complex data type ADDRESS. This data type is based on the code of class Address.

For more information on how to use a class as a data type, see the "Attaching a classifier to a data type or a return type" section in the Building Structural Diagrams chapter.

When you apply a persistent complex data type to a class attribute or a domain, you can define the following different generation options:

- Standard data type generation
- Embedded data type generation

Generating as Persistent Class

In the Detail page of the property sheet of an attribute using a complex data type, you have to select:

- The Persistent check box
- Persistent in the Class Generation list

After OOM to CDM generation, both classes become entities and a relationship is created between them. The class used as data type contains a new primary identifier attribute.

Example

If you define the standard data type generation options in the Address/Customer example, the generated CDM is the following:

The new column `Address_ID` is the primary identifier in entity `Address`.

Generating as Embedded Class

In the Detail page of the property sheet of an attribute using a complex data type, you have to select:

- The Persistent check box
- Embedded in the Class Generation list

After OOM to CDM generation, all the attributes of the class used as data type are embedded into the entity containing the attribute with complex data type. These attributes are prefixed by the name of the attribute using the complex data type.

Example

If you define the embedded data type generation options in the `Address/Customer` example, the generated CDM is the following:

Address	
line1	TXT
line2	TXT
city	TXT
zipCode	TXT
country	TXT

Customer	
number	I
lastName	TXT
company	TXT
address_line1	TXT
address_line2	TXT
address_city	TXT
address_zipCode	TXT
address_country	TXT

All the attributes of class `Address` are embedded into entity `Customer` and prefixed by "address" which is the name of the attribute using `Address` as complex data type.

Managing Multiplicity for Complex Persistent Data Types

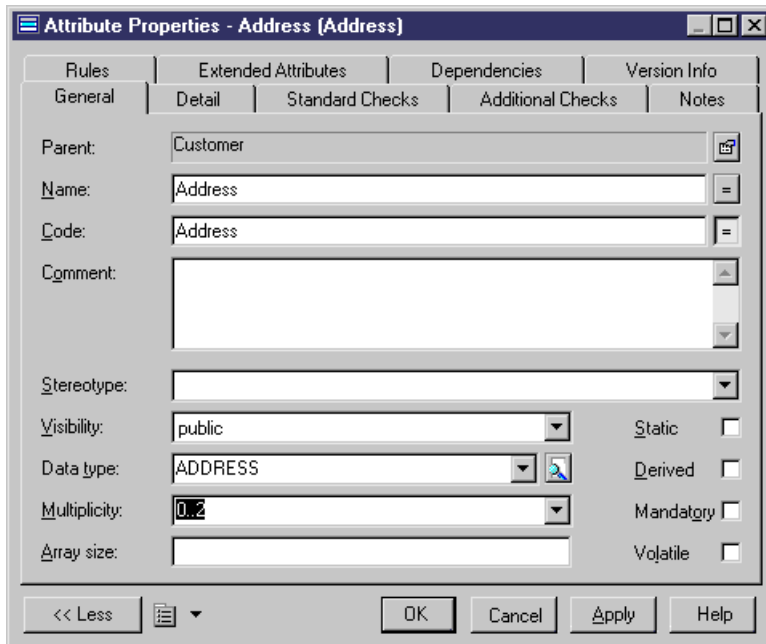

If you define a multiplicity on a class attribute with a complex data type, the generation will reflect this multiplicity.

In the following example, attribute `address` in class `Customer` has a complex data type based on class `Address`.

Address	
+ line1	: String
+ line2	: String
+ city	: String
+ zipCode	: String
+ country	: String

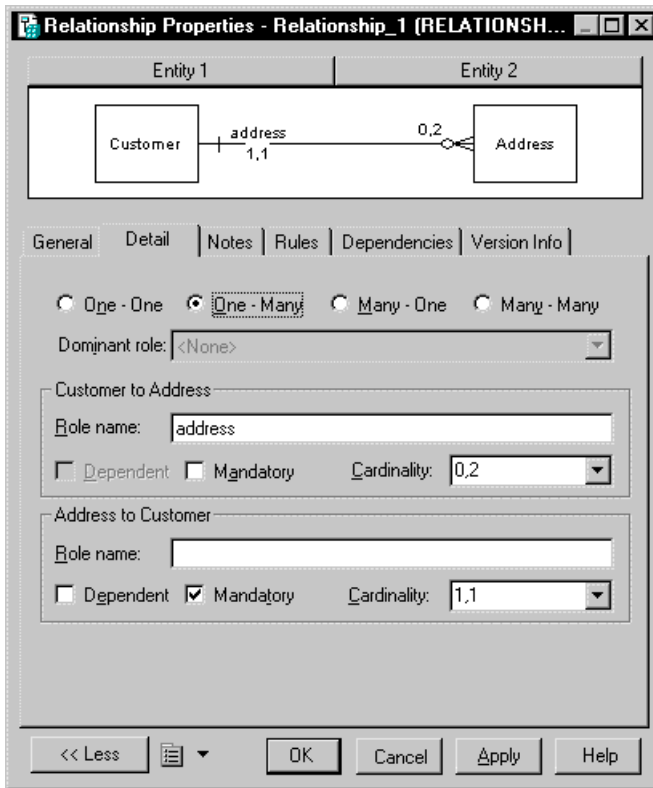

Customer	
+ number	: int
+ lastName	: String
+ company	: String
+ address	: ADDRESS

You also define the multiplicity 0..2 for attribute `address`:

Generating as Persistent Class

When the Persistent check box is selected for the attribute and the class generation is also set to Persistent, then the attribute multiplicity becomes a cardinality on the relationship between entities after OOM to CDM generation.

Generating as Embedded Class

When the Persistent check box is selected for the attribute and the class generation is set to Embedded, all the attributes of the class used as data type are embedded into the entity containing the attribute with complex data type. Attributes are generated as many times as required by multiplicity, provided multiplicity indicates a fixed value.

In the following example, attribute multiplicity is 0..2, so attributes will be embedded twice:

Address	
line1	TXT
line2	TXT
city	TXT
zipCode	TXT
country	TXT

Customer	
number	I
lastName	TXT
company	TXT
address1_line1	TXT
address1_line2	TXT
address1_city	TXT
address1_zipCode	TXT
address1_country	TXT
address2_line1	<UNDEF>
address2_line2	<UNDEF>
address2_city	<UNDEF>
address2_zipCode	<UNDEF>
address2_country	<UNDEF>

Embedded generation of complex data types is not possible when multiplicity is undefined (0..n).

Managing Object Persistence During OOM to PDM Generation

Developers tend to use object-oriented programming languages like Java, to develop business objects and components. Eventually, these objects need to be stored in a database, then a problem arises when the user tries to store objects in a relational database because object codes in object-oriented programming languages are often different than codes used in a relational database.

You have to modify object codes after generating an OOM into a PDM to be compliant with the DBMS.

You can define persistent codes to bypass this impedance-mismatch.

You can also create object to relational mappings between OOM and PDM objects to further define the links between objects from different models (see *Chapter 12, Object Mappings* in the *Core Features Guide*).

Defining Object Persistence in the OOM

Persistent codes are defined for OOM classes and attributes. They are used during OOM to PDM generation in order to fine tune data storage in a relational database. They also facilitate round-trip engineering by allowing to recover object codes from the database.

You can define the type of persistence you want to implement in the Persistent group box in the Detail tab of a class property sheet:

- Generate table means the class is generated in a table.
- Migrate columns means the class is not generated, its attributes and associations are migrated to the generated parent or child table.

- Generate ADT means the class is generated as an abstract data type, a user-defined data type that can encapsulate a range of data values and functions.

Attribute and associations of persistent classes with a persistence generation mode set to "Migrate columns" are migrated to parent or child tables.

You can also define persistent data types for class attributes and domains. For data type persistence management, you have to take into account the following parameters:

- The data type is *simple*, based on standard OOM data types. If the data type is persistent, generation keeps persistent data type in the target model. Otherwise data type is converted to standard data type in the target model
- The data type is *complex*, based on a classifier. If the data type is persistent, you can define different generation options according to what you want to have in the target model and to the attribute multiplicity

Attribute Migration

If you generate the following OOM into a PDM:

The migration of attributes in the generated PDM depends on the persistence option of the classes in the source OOM:

Persistence	Result
Parent and child / Generate table	Two tables are created for each class
Parent / Migrate columns Child / Generate table	Table Child is generated with parent attributes
Parent / Generate table Child / Migrate columns	Table Parent is generated, with child attributes
Parent and child / Migrate columns	Nothing is generated

Inherited Attributes

In the following OOM, class Customer inherits from Person via a generalization link. Person is not persistent but Customer is persistent.

Customer inherits the attributes of the parent class in the generated PDM:

Customer	
Client ID	integer
Order N°	integer
Name	char
Last name	char
Address	char

Derived Class

A derived class is created for conceptual reasons to improve the readability of a model but it adds no semantic information. There is no point of generating a derived class in a PDM, and attributes of this class should be migrated to parent.

In the following example, class Women is created to further analyze class Employee and highlight a specific attribute "Maternity leave". This class is derived, thus not generated but persistent:

In the generated PDM, Employee inherits from parent class and also from derived class:

Employee	
Emp ID	integer
Department	integer
Name	char
Last name	char
Address	char
Maternity leave	smallint

Managing Complex Data Type Persistence

In the following example, both classes are defined as persistent.

Class Customer contains an attribute address with a complex data type ADDRESS. This data type is based on the code of class Address.

For more information on how to use a class as a data type, see *Attaching a Classifier to a Data Type or a Return Type* on page 45.

When you apply a persistent complex data type to a class attribute or a domain, you can define the following different generation options:

- Standard data type generation
- Embedded data type generation
- Abstract data type generation

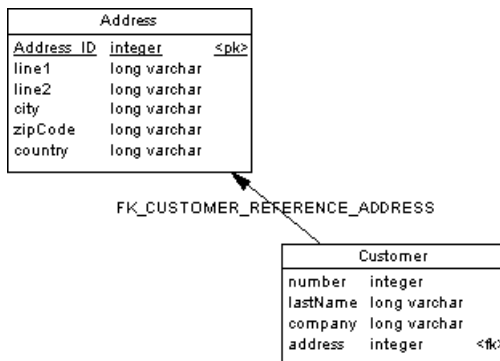

Generating as Persistent Class

In the Detail page of the property sheet of an attribute using a complex data type, you have to select:

- The Persistent check box
- Persistent in the Class Generation list

After OOM to PDM generation, both classes become tables and a reference is created between them. This reference contains a join linking the primary key column in the parent table Address (this column is new, it was created during generation) and the foreign key column in the child table Customer. The foreign key column stands for the attribute using a complex data type in the OOM.

For example, if you define the standard data type generation options in the Address/Customer example, the generated PDM is the following:

The reference contains a join between Address_ID (new column in table Address) and address in child table Customer. Address_ID contains the primary key migrated to column address.

Generating as Embedded Class

In the Detail page of the property sheet of an attribute using a complex data type, you have to select:

- The Persistent check box
- Embedded in the Class Generation list

After OOM to PDM generation, all the attributes of the class used as data type are embedded into the table containing the attribute with complex data type. These attributes are prefixed by the name of the attribute using the complex data type.

For example, if you define the embedded data type generation options in the Address/ Customer example, the generated PDM is the following:

Address	
line1	long varchar
line2	long varchar
city	long varchar
zipCode	long varchar
country	long varchar

Customer	
number	integer
lastName	long varchar
company	long varchar
address_line1	long varchar
address_line2	long varchar
address_city	long varchar
address_zipCode	long varchar
address_country	long varchar

All the attributes of class Address are embedded into table Customer and prefixed by "address" which is the name of the attribute using Address as complex data type.

Generating as Abstract Data Type Class

In the Detail page of the property sheet of an attribute using a complex data type, you have to select:

- The Persistent check box
- Embedded in the Class Generation list

You also have to select the Abstract Data Type check box in the Detail page of the property sheet of the class used as data type.

After OOM to PDM generation, the class used as data type becomes an abstract data type.

For example, if you define the abstract data type generation options in the Address/Customer example, the generated PDM is the following:

Customer	
number	INTEGER
lastName	LONG
company	LONG
address	Address

Class Address is generated as an abstract data type attached to column address in table Customer.

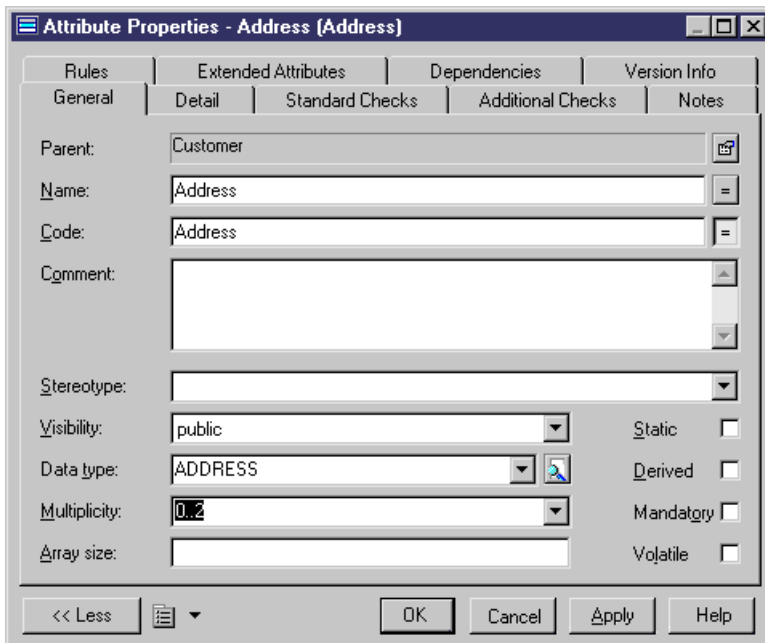

Managing Multiplicity for Complex Persistent Data Types

If you define a multiplicity on a class attribute with a complex data type, the generation will reflect this multiplicity.

In the following example, attribute address in class Customer has a complex data type based on class Address.

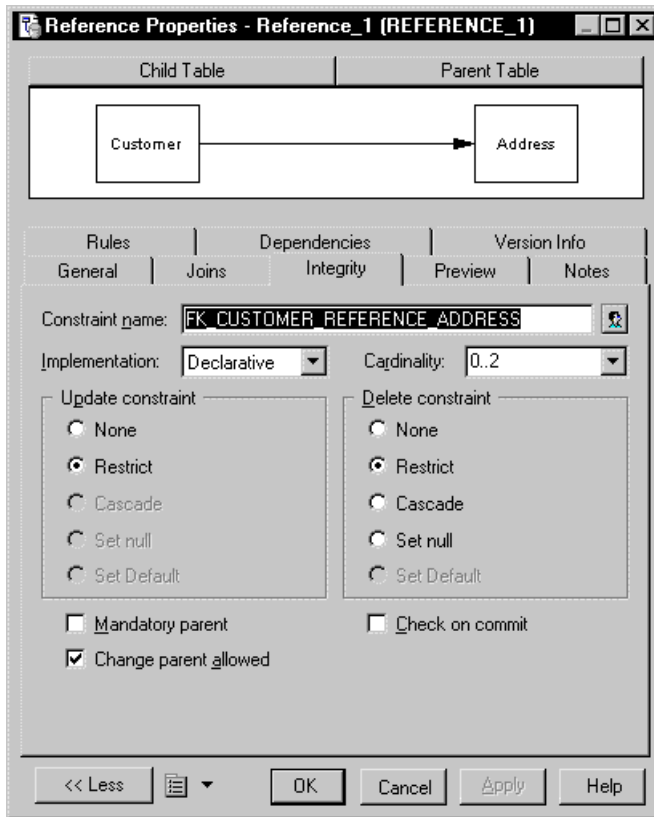

You also define the multiplicity 0..2 for attribute address:

Generating as Persistent Class

When the Persistent check box is selected for the attribute and the class generation is also set to Persistent, then the attribute multiplicity becomes a cardinality on the reference between tables after OOM to PDM generation.

Generating as Embedded Class

When the Persistent check box is selected for the attribute and the class generation is set to Embedded, all the attributes of the class used as data type are embedded into the table containing the column created for the attribute with complex data type. Attributes are generated as many times as required by multiplicity, provided multiplicity indicates a fixed value.

In the following example, attribute multiplicity is 0..2, so attributes will be embedded twice:

Address	
line1	LONG
line2	LONG
city	LONG
zipCode	LONG
country	LONG

Customer	
number	INTEGER
lastName	LONG
company	LONG
address1_line1	LONG
address1_line2	LONG
address1_city	LONG
address1_zipCode	LONG
address1_country	LONG
address2_line1	LONG
address2_line2	LONG
address2_city	LONG
address2_zipCode	LONG
address2_country	LONG

Embedded generation of complex data types is not possible when multiplicity is undefined (0..n).

Generating as Abstract Data Type Class

When both attribute and class generation are set to Persistent, and when the class used as data type is generated as an abstract data type, the class is generated as an abstract data type without taking into account the multiplicity of the generated attribute.

However, for those DBMS that support ARRAY and LIST for abstract data types, the generation of a class into an abstract data type can reflect the attribute multiplicity in the following way:

Multiplicity	Generated as
0..n or 1..n	Abstract data type with the LIST type (example: TABLE for Oracle)
1..2 or 0..10	Abstract data type with the ARRAY type (example: VARRAY for Oracle)
0..1 or 1..1	Abstract data type with the OBJECT type

CHAPTER 9 Customizing the OOM Environment

The OOM environment includes a set of parameters and configuration options that define various aspects of the model content and behavior. You can set these parameters:

- At model creation
- After creating a model with default options and parameters
- When creating a model template

Working with Object Language

An object language contains specifications for a particular language. It provides PowerDesigner with the syntax and guidelines for implementing stereotypes, data types, scripts and constants for an object language.

Each OOM is by default attached to an object language. When you create a new OOM, you must choose an object language. You can create a new object language or use the languages delivered with PowerDesigner.

The definition of an object language is available from its property sheet. You can select and configure parameters used when defining objects or generating from an OOM.

For more information on object languages, see "Resource File Reference" in the Resource Files and the Public Metamodel chapter of the *Customizing and Extending PowerDesigner* manual.

In an OOM, you can use the List of Object languages to display the properties of object languages, and to compare, or merge object languages.

For more information on using the list of object languages, see "Working with PowerDesigner Resource Files" in the Resource Files and the Public Metamodel chapter of the *Customizing and Extending PowerDesigner* manual.

Note: Some resource files are delivered with "Not Certified" in their names. Sybase will perform all possible validation checks, however Sybase does not maintain specific environments to fully certify these resource files. Sybase will support the definition by accepting bug reports and will provide fixes as per standard policy, with the exception that there will be no final environmental validation of the fix. Users are invited to assist Sybase by testing fixes of the definition provided by Sybase and report any continuing inconsistencies.

Previewing the Code of an OOM

You can preview the code of a model or package in order to see the generated code, by clicking the Preview tab. The displayed code changes according to the object language you have selected in your model.

For example, if you have created EJB or servlet components in Java, the Preview tab displays the EJB or Web deployment descriptor files. If you have selected an XML family language, the Preview tab displays the Schema file that corresponds to the XML file to be generated.

You can use the following tools and keyboard shortcuts from the Preview toolbar:

Tool	Description	Keyboard shortcut
	Open Editor Contextual menu	Shift + F11
	Refresh	F5
	Show Generation Options	ctrl + W
	Select Generation Targets	ctrl + F6

Showing Generation Options

If you click the Show Generation Options tool, the Generation Options dialog box is displayed. You can change generation options from this dialog box.

Select Generation Targets

When available, this tool displays the list of target extended model definitions selected for generation. If you add a generation target, the corresponding tab is added to the Preview tab. If you deselect a generation target, the corresponding tab disappears from the Preview tab. This tool is disabled if no target extended model definition is attached to the model.

For more information on the generation targets, see *Working with Generation Targets* on page 278.

Script Bookmarks

In the Preview tab, you can add and remove bookmarks at specific points in the code and then navigate forwards or backwards from bookmark to bookmark:

Keyboard shortcut	Description
ctrl + F2	Adds a new bookmark. A blue bookmark box is displayed. If you repeat this action from the same position, the bookmark is deleted and the blue marker disappears
F2	Jumps to bookmark
shift + F2	Jumps to previous bookmark

Note that bookmarks are not printable and are lost if you use the Refresh, or Show Generation Options tools.

Modifying the Code Using Preview

You can modify the code directly from the Preview tab of a class or an interface, it is a quick and easy way to apply modifications to your code and update the model.

If you want to modify the code, you have to select the Preview Editable check box from **Tools > Model options**. This option is applicable to the entire model. Any changes apply as soon as you leave the Preview tab, or you click the Apply button. Your changes are also displayed in the Output window located in the lower part of the main window.

The code modified must contain a valid definition otherwise the changes are ignored. Your changes only apply to the current class or interface, therefore you are not allowed to:

- Move the classifier to another package by changing the package declaration
- Rename a classifier

You are allowed to create generalization and realization links provided their classifiers already exist in the model, if the classifiers do not exist, then creation is ignored.

In a model designed for *PowerBuilder*, this feature can be used to provide a global vision of the code of an object and its functions as this is not available in PowerBuilder. You can use the Preview tab to check where instance variables are used in the code. You can also modify the body of a function or create a new function from an existing function using copy/paste. However, it is still strongly recommended to be very careful when performing such actions.

Warning! You should avoid renaming attributes and operations because all attributes that are not generated, like description, annotation or extended attributes will be lost.

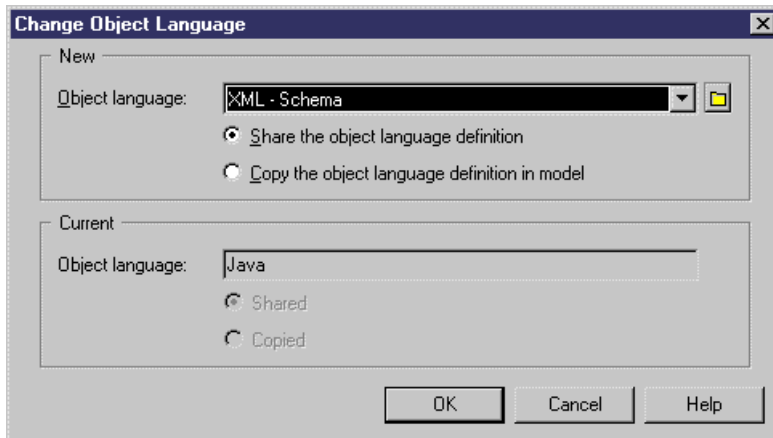

Changing the Object Language of an OOM

You can change the object language of a model at any time.

You may be required to change the object language if you open an OOM and the associated language file has been deprecated, or is otherwise unavailable. In this case the "Choose Object Language" dialog box will be displayed, inviting you to select a language from the list.

Object languages are frequently updated in each version of PowerDesigner and it is highly recommended to accept this change, or otherwise you will not be able to generate for the selected language.

1. Select **Language > Change Current Object Language** to open the Change Object Language dialog box .

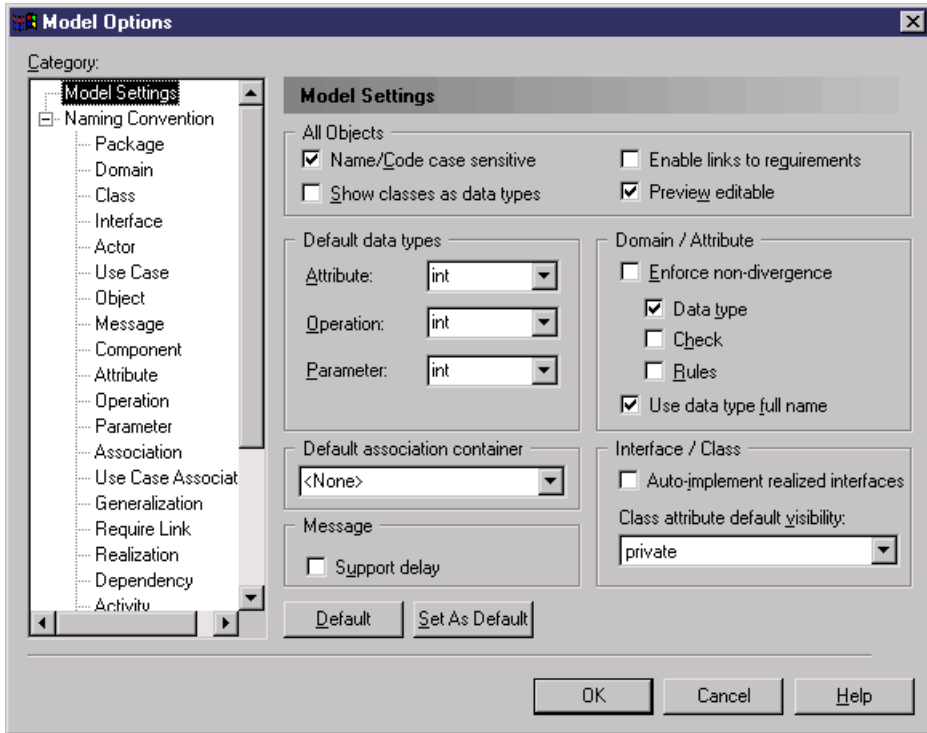

2. Select an object language.
3. Select one of the following radio buttons:
 - Share the object language definition – use the original object language file in the "Resource Files\Object Languages" directory. Any changes made to the object language are shared by all linked OOM.
 - Copy the object language definition in model – make a copy of the original object language file in the "Resource Files\Object Languages" directory. The current object language is independent of the original object language, so modifications made to the object language in the Object Languages directory are not available to the OOM. The copied object language is saved with the OOM and cannot be used without it.

Warning! PowerDesigner is delivered with a set of object languages. It is strongly advised to make a backup copy of each object language before you start modifying them.

4. Click OK.
A message box informs you that the current object language has been changed.
5. Click OK.

Setting OOM Model Options

You can set OOM model options by selecting **Tools > Model Options** or right-clicking the diagram background and selecting **Model Options**. These options affect all the objects in the model, including those already created.

You can set the following options:

Option	Definition
All Objects: Name/Code case sensitive	<p>You can define the case sensitivity of names and codes for all objects in the current model. When this check box is selected, it implies that you can have two objects with identical name or code but different case in the same namespace.</p> <p>Unlike other model options, you can modify the name and code case sensitivity during the design process. However, if you do so, make sure you run the check model feature to verify if the model does not contain any duplicate object.</p>

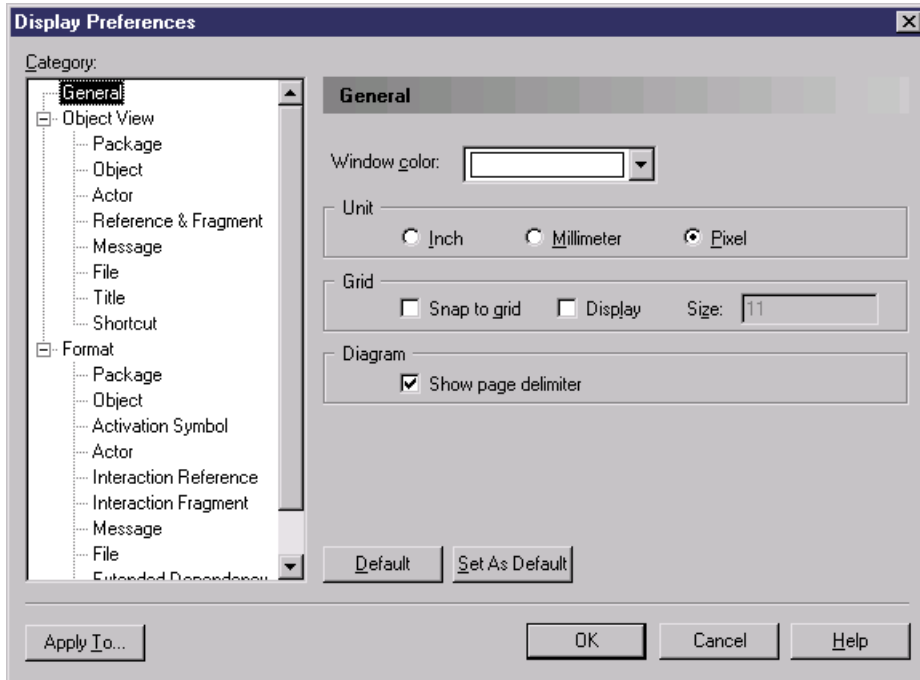

Option	Definition
All Objects: Enable links to requirements	Displays a Requirements tab in the property sheet of every object in the model. Requirements are descriptions of customer needs that must be satisfied during the development process, and are defined in requirements models. The Requirements tab allows you to attach requirements to objects in your model. These attached requirements are kept synchronized with your requirements model. For more information on requirements, see the <i>Requirements Modeling</i> guide.
All Objects: Show classes as data types	Includes classes of the model in the list of data types defined for attributes or parameters, and return types defined for operations.
All Objects: Preview editable	Applies to reverse engineering. You can edit your code from the Preview page of a class or an interface by selecting the Preview Editable check box. This allows you to reverse engineer changes applied to your code directly from the Preview page.
Default Data Types	Specifies default data types for attributes, operations, and parameters. If you type a data type value that does not exist in the BasicDataTypes and AdditionalDataTypes lists of the object language, then the value of the DefaultDataType entry is used. For more information on data types in the object language, see "Settings category" in the Resource Files and the Public Metamodel chapter of the <i>Customizing and Extending PowerDesigner</i> manual.
Domain/Attribute: Enforce non-divergence	Specifies that attributes attached to a domain must remain synchronized with the properties of that domain. You can specify any or all of: <ul style="list-style-type: none"> • Data type – data type, length, and precision • Check – check parameters, such as minimum and maximum values • Rules – business rules
Domain/Attribute: Use data type full name	Specifies that the full data type name is used for attribute data types instead of its abbreviated form. Provides a clear persistent data type list for attributes.
Default Association Container	Specifies a default container for associations that have a role with a multiplicity greater than one.
Message: Support delay	Specifies that messages may have duration (slanted arrow message). If this option is deselected, messages are treated as instantaneous, or fast (horizontal message).
Interface/Class: Auto-implement realized interfaces	Adds to the realizing class any methods of a realized interface and its parents that are not already implemented by the class. The <<implement>> stereotype is applied to the methods.
Interface/Class:	Specifies the default visibility of class attributes.

Note: For information about specifying naming conventions for your model objects, see .

Setting OOM Display Preferences

PowerDesigner display preferences allow you to customize the format of object symbols, and the information that is displayed on them.

To set OOM display preferences, select **Tools > Display Preferences** or right-click the diagram background and select Display Preferences from the contextual menu.

To set display preferences for a particular object, select it under the Object View category. The following table provides an alphabetical list of the display preferences available. Note that each object supports only some of these preferences, and that the objects available to be customized in the Display Preferences window depend upon the current diagram type.

Note: For information about changing the format of symbols, see "Format display preferences" in the Customizing your Modeling Environment chapter of the *Core Features Guide*.

Preference	Description
Actions	<p>[states] Controls whether actions are displayed. If selected, allows you to further choose between:</p> <ul style="list-style-type: none"> • All - Display all actions • Limit – Display actions up to the limit specified in the adjacent box <p>You can then, additionally, specify whether event arguments will be shown.</p>
Activation attachment	[messages in sequence diagrams] Displays an endpoint at the intersection of the message and the activation.
Activity Parameter	[activities] Displays the boxes that represent the parameters of the activity, on the edge of its symbol.
Association name	[instance links] Displays the name of the association that the instance link refers to.
Association role names	[instance links] Displays the names of the association roles.
Attribute values	[objects] Displays attributes and attribute values of the object.
Attributes	<p>[classes and interfaces] Controls whether classifier attributes are displayed. If selected, allows you to further choose between:</p> <ul style="list-style-type: none"> • All - Display all attributes • Limit – Display attributes up to the limit specified in the adjacent box
Comment	Displays the comment of the object.
Constraints	Displays the constraints (business rules) of the object.
Data type	[attributes] Displays the data type of the attribute.
Direction	<p>[use case associations] Displays the orientation of the association. If you want to respect the UML methodology, you can set Direction as not selected by default. If you do want to display the association direction, you can use the association display preferences to modify it.</p> <p>If no direction is displayed, the position of actors in the diagram implicitly provides the direction of associations. When an actor is positioned to the left of the use case, the association goes from the actor to the use case; inversely, when an actor is positioned to the right of the use case, the association goes from the use case to the actor.</p>
Display Instance	[activity parameters] Displays target parameters on activities.
Domain	[attributes] Displays the domain attached to the attribute
Event arguments	[transitions] Displays the arguments of the events associated with the transition.

Preference	Description
Headers always visible	[actors and objects in sequence diagrams] Always displays the actor or object name in the upper part of the diagram, whatever the length of the actor lifeline.
Initial value	[attributes] Displays the initial value of the attribute upon instantiation of the class
Inner classifiers	[classes and interfaces] Displays inner classifiers attached to the classifier.
Interaction Symbol	[interaction frames] Displays a frame around the sequence diagram, which acts as its border, and can be used to represent the sender or receiver of a message.
Interface Name	[assembly connectors] Displays the names of the connector's interfaces.
Lifeline attachment	[interaction fragments and references] Displays the marks that signify an attachment of the fragment or reference to an object or actor lifeline.
Location	[files] Displays the path to the file.
Multiplicity	[associations and node associations] Displays the multiplicity of the relationship. You can choose between the actual number of instances (String) or the symbol at each end of the relationship (Symbol)
Name	<p>Displays the name of the object.</p> <p>For messages in sequence diagrams, you can additionally set the following sub-options:</p> <ul style="list-style-type: none"> • Replace by operation name – if the message is linked to an operation, the name of the operation is displayed instead of the name of the message. • Sequence expression - Displays the message predecessor list, sequence number, and condition • Signature - Displays the message arguments and return value. <p>For ports, you can additionally set the following sub-options:</p> <ul style="list-style-type: none"> • Type. • Multiplicity
Name if no condition	[decisions] Displays a user-defined name if no condition is specified.
Network address	[nodes] Displays node address.
Operations	<p>[classes and interfaces] Controls whether classifier operations are displayed. If selected, allows you to further choose between:</p> <ul style="list-style-type: none"> • Type - Display all operations • Limit – Display operations up to the limit specified in the adjacent box
Ordering	[associations] Displays the ordering type chosen

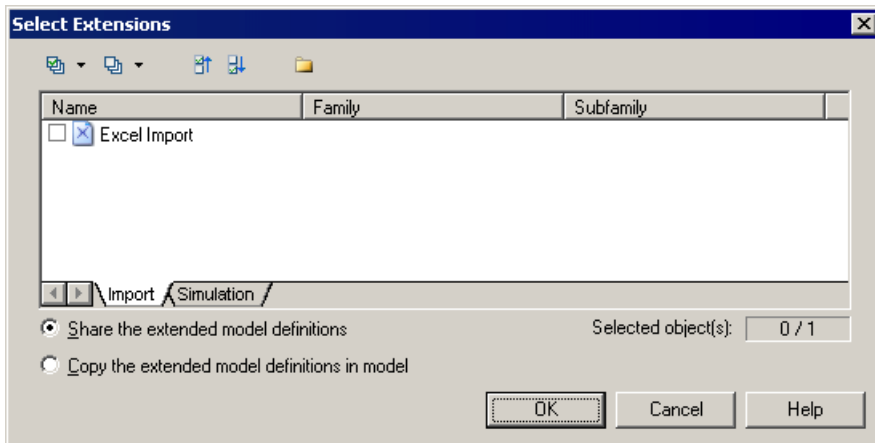

Preference	Description
Organization unit swimlane	[sequence diagram – in General category] Displays organization units as swimlanes. When selected, you can choose between Horizontal and a Vertical lanes.
Parameters	[operations] Displays the operation parameters
Return type	[operations] Displays the operation return type
Role names	[associations and node associations] Displays the name of the association roles.
Stereotype	Displays the stereotype of the object.
Time	[messages in sequence diagrams] Displays the begin and end times.
Type	[components, component instances, and parts] Displays the type of the object.
Visibility	[attributes and operations] Specifies how these objects will be displayed. You can choose between: <ul style="list-style-type: none"> • Use icons - Display as an icon • Use markers - Display as a marker: - (private), # (protected), + (public), or * (package) • Use keywords - Display as a word: private, protected, public, or package

Extending Your Modeling Environment with Extended Model Definitions

Extended model definitions (.XEM files) allow you to customize and extend PowerDesigner metaclasses, parameters and generation.

You access the features defined in an extended model definition by attaching the file to your model. You can do this when creating a new model by clicking the **Select Extensions** button at the bottom of the New Model dialog, or at any time by selecting **Model > Extended Model Definitions** to open the List of Extended Model Definitions and clicking the **Import an Extended Model Definition** tool.

In each case, you arrive at the Select Extensions dialog, which lists the extensions available, sorted on sub-tabs, which depend on the type of model you are working with:

For information about developing extended model definitions, see *Chapter 1, Resource Files and the Public Metamodel* in *Customizing and Extending PowerDesigner*.

Creating Links with Extended Dependencies

Extended dependencies can be created between any model objects, including between objects in different models. They are used for documentation purposes only, and are not interpreted or checked by PowerDesigner.

For more information about extended dependencies, see "Creating Extended Dependencies" in *Chapter 9, Getting Started with Linking and Syncing* of the *Core Features Guide*.

CHAPTER 10 Checking an OOM

The Object-Oriented Model is a very flexible tool, which allows you quickly to develop your model without constraints. You can, however, check the validity of your OOM at any time.

Note: We recommend that you check your OOM before generating code from it. If the check encounters errors, generation will be stopped. The Check model option is enabled by default in the Generation dialog box.

You can check an OOM in any of the following ways:

- Press F4, or
- Select **Tools > Check Model**, or
- Right-click the diagram background and select Check Model from the contextual menu

The Check Model Parameters window opens, which allows you to specify the kinds of checks to perform, and the objects to apply them to. For detailed information about this window and correcting problems reported, see "Checking a Model" in the Models chapter of the *Core Features Guide*.

The following sections document the OOM-specific checks available by default. For information about checks made on generic objects available in all model types, see "Checking a Model" in the Models chapter of the *Core Features Guide*.

Domain Checks

PowerDesigner provides default model checks to verify the validity of domains.

Check	Description and Correction
Domain name and code uniqueness	Domain names and codes must be unique in the model. Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Inconsistency between default values and check parameters	The values entered in the check parameters tab are inconsistent for numeric and string data types: default does not respect minimum and maximum values, or default does not belong to list of values, or values in list are not included in minimum and maximum values, or minimum is greater than maximum value. Check parameters must be defined consistently. Manual correction: Modify default, minimum, maximum or list of values in the check parameters tab Automatic correction: None

Data Source Checks

PowerDesigner provides default model checks to verify the validity of data sources.

Check	Description and Correction
Data source name and code uniqueness	Data source names and codes must be unique in the model. Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Existence of physical data model	A data source must have at least one physical data model in its definition. Manual correction: Add a physical data model from the Models tab of the property sheet of the data source Automatic correction: Deletes data source without physical data model
Differing DBMS types	The models in a data source represent a single database. This is why the models in the data source should share the same DBMS. Manual correction: Delete models with different DBMS or modify the DBMS of models in the data source Automatic correction: None

Package Checks

PowerDesigner provides default model checks to verify the validity of packages.

Check	Description and Correction
Circular inheritance	Objects cannot be dependent on each other. Circular links must be removed. Manual correction: Remove circular generalization links Automatic correction: None
Circular dependency	Classes are dependent on each other through association class and/or generalization links. Circular links must be removed. Manual correction: Remove circular links Automatic correction: None
Shortcut code uniqueness	Two shortcuts with the same code cannot be in the same namespace. Manual correction: Change the code of one of the shortcuts Automatic correction: None

Check	Description and Correction
Shortcut potentially generated as child table of a reference	<p>The package should not contain associations with an external shortcut as child class. Although this can be tolerated in the OOM, the association will not be generated in a PDM if the external shortcut is generated as a shortcut.</p> <p>Manual correction: Modify the design of your model in order to create the association in the package where the child class is defined</p> <p>Automatic correction: None</p>

Actor/Use Case Checks

PowerDesigner provides default model checks to verify the validity of actors and use cases.

Check	Description and Correction
Actor/use case name and code uniqueness	<p>Actor and use case names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Actor/use case not linked to any object	<p>Actors and use cases should be linked to at least one object in the model.</p> <p>Manual correction: Create a link between the actor and a use case, or an object</p> <p>Automatic correction: None</p>

Class Checks

PowerDesigner provides default model checks to verify the validity of classes.

Check	Description and Correction
Class name and code uniqueness	<p>Class names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Empty classifier	<p>Attributes and operations are missing for this classifier.</p> <p>Manual correction: Add attributes or operations to the classifier</p> <p>Automatic correction: None</p>
Persistent class without persistent attributes	<p>All attributes of a persistent class cannot be non-persistent.</p> <p>Manual correction: Define at least one attribute as persistent</p> <p>Automatic correction: None</p>

Check	Description and Correction
Association class with identifier(s)	<p>An associated class should not have identifiers.</p> <p>Manual correction: Remove the identifier</p> <p>Automatic correction: None</p>
Classifier visibility	<p>A private or protected classifier should be inner to another classifier.</p> <p>Manual correction: Change classifier visibility to public or package</p> <p>Automatic correction: Changes the visibility to public or package</p>
Class constructor return type	<p>A constructor cannot have a return type.</p> <p>Manual correction: Remove current return type of the constructor</p> <p>Automatic correction: Removes current return type of the constructor</p>
Class constructor modifiers	<p>A constructor cannot be static, abstract, or final.</p> <p>Manual correction: Remove the static, abstract, or final property of the constructor</p> <p>Automatic correction: Removes the static, abstract or final property of the constructor</p>
Operation implementation	<p>When there is a realization between a class and an interface, you must implement the operations of the interface within the class. To do so, click the Operations tab in the class property sheet and select the To be Implemented button at the bottom of the tab to implement the missing operations.</p> <p>Manual correction: Implement the operations of the interface within the class</p> <p>Automatic correction: None</p>
Role name assignment	<p>A navigable role will be migrated as an attribute into a class. The code of the association is used if the role has no name.</p> <p>Manual correction: Assign a role name for the association role</p> <p>Automatic correction: None</p>
Role name uniqueness	<p>The name of the role is used by another role or by another attribute.</p> <p>Manual correction: Change the name of the duplicate role</p> <p>Automatic correction: None</p>
JavaBean without a BeanInfo	<p>Bean implementors that provide explicit information about their beans must provide a BeanInfo class.</p> <p>Manual correction: Create a BeanInfo class</p> <p>Automatic correction: None</p>

Check	Description and Correction
BeanInfo without a JavaBean class	<p>A BeanInfo class must depend on a JavaBean class.</p> <p>Manual correction: Create a JavaBean class and recreate its BeanInfo, or delete the BeanInfo</p> <p>Automatic correction: None</p>
Emuneration type parent	<p>A enum may not have children.</p> <p>Manual correction: Remove links to child classes.</p> <p>Automatic correction: None</p>
Bean class definition	<p>The Bean class must be defined as public. It must define a public constructor that takes no arguments and cannot define the finalize() method. It must be abstract for CMP Entity Beans but cannot be abstract or final for BMP Entity, Session and Message-driven Beans.</p> <p>Manual correction: Change the class visibility to public, define a public constructor with no arguments, do not define the finalize() method</p> <p>Automatic correction: Changes the class visibility to public, defines a public constructor with no arguments and removes the finalize() method. Corrects to set final = false, and set abstract = false</p>
Bean class Business methods implementation	<p>For each method defined in the component interface(s), there must be a matching method in the Bean class that has the same name, number, return type and types of arguments.</p> <p>Manual correction: Add a method with the same name, number, return type and types of arguments in the Bean class</p> <p>Automatic correction: Adds a method with the appropriate values in the Bean class</p>

Check	Description and Correction
<p>Bean class Home interface methods implementation</p>	<p>For each create<METHOD> method of the bean Home Interface(s), there must be a matching ejbCreate<METHOD> method in the Bean class with the same method arguments. For each home method of the Home Interface(s), there must be a matching ejbHome<METHOD> method in the Bean class with the same number and types of arguments, and the same return type.</p> <p>The following check applies to <i>Entity Beans only</i>.</p> <p>For each ejbCreate<METHOD> method of the Bean class, there must be a matching ejbPostCreate<METHOD> method in the Bean class with the same number and types of arguments.</p> <p>Manual correction: Add a method with the same name and types of arguments in the Bean class</p> <p>Automatic correction: Adds a method with the appropriate values in the Bean class</p> <p>The following check applies to <i>BMP Entity Beans only</i>.</p> <p>For each find<METHOD> finder method defined in the bean Home Interface(s), there must be a corresponding ejbFind<METHOD> method with the same number, return type, and types of arguments.</p> <p>Manual correction: Add a method with the same number, return type and types of arguments in the bean Home Interface(s)</p> <p>Automatic correction: Adds a method with the appropriate values in the bean Home Interface(s)</p>

Check	Description and Correction
Bean class ejb-Create methods	<p>ejbCreate<METHOD> methods must be defined as public, and cannot be final nor static.</p> <p>The following check applies to <i>Entity Beans only</i>.</p> <p>The return type of an ejbCreate() method must be the primary key type.</p> <p>Manual correction: Select the primary key in the Return type list of the Operation property sheet</p> <p>Automatic correction: Selects the primary key as return type</p> <p>The following check applies to <i>Session Beans and Message Driven Beans. and Message Driven Beans</i>.</p> <p>The return type of an ejbCreate() method must be void.</p> <p>Manual correction: Select void in the Return type list of the Operation property sheet</p> <p>Automatic correction: Changes the return type to void</p> <p>The following check applies to <i>Message Driven Beans only</i>.</p> <p>The Bean class must define an ejbCreate() method that takes no arguments.</p> <p>Manual correction: Add a method with no argument in the Bean class</p> <p>Automatic correction: Adds a method with no argument in the Bean class</p>
Bean class ejbPost-Create methods	<p>The following check applies to <i>Entity Beans only</i>.</p> <p>ejbPostCreate<METHOD> methods must be defined as public, and cannot be final nor static. Their return type must be void.</p> <p>Manual correction: Change the method visibility to public, deselect the final and static check boxes and select void in the Return type list of the Operation property sheet</p> <p>Automatic correction: Changes the method visibility to public, changes the final and static check boxes and changes the return type to void</p>
Bean class ejbFind methods	<p>BMP Entity Bean specific.</p> <p>ejbFind<METHOD> methods must be defined as public and cannot be final nor static. Their return type must be the entity bean primary key type or a collection of primary keys.</p> <p>Manual correction: Change the method visibility to public and deselect the static check box</p> <p>Automatic correction: Changes the method visibility to public and deselects the static and final check boxes. Forces the return type of ejbFind<METHOD> to the primary key type</p>

Check	Description and Correction
Bean class ejbHome methods	<p>ejbHome<METHOD> methods must be defined as public and cannot be static.</p> <p>Manual correction: Change the method visibility to public and deselect the static check box</p> <p>Automatic correction: Changes the method visibility to public and deselects the static check box</p>
Bean class ejbSelect methods	<p>The following check applies to <i>CMP Entity Beans only</i>.</p> <p>EjbSelect <METHOD> methods must be defined as public and abstract. Their throws clause must include the javax.ejb.FinderException.</p> <p>Manual correction: Change the method visibility to public, select the abstract check box, and include the javax.ejb.FinderException</p> <p>Automatic correction: Changes the method visibility to public, selects the abstract check box, and includes the javax.ejb.FinderException</p>
Primary key class definition	<p>The following check applies to <i>Entity Beans only</i>.</p> <p>The primary key class must be declared as public and must define a public constructor that takes no arguments.</p> <p>Manual correction: Change the method visibility to public and add a default constructor in the primary key class</p> <p>Automatic correction: Changes the method visibility to public and adds a default constructor in the primary key class</p>
Primary key class attributes	<p>All primary key class attributes must be declared as public. In addition, each primary key class attribute must have a corresponding cmp-field in the Bean class.</p> <p>Manual correction: Change the visibility to public, and create a cmp-field in the Bean class that has the same name and the same data type as the attribute of the primary key class</p> <p>Automatic correction: Changes the visibility to public and creates a cmp-field in the Bean class that has the same name and the same data type as the attribute of the primary key class</p>
Primary key class existence	<p>If the bean class has more than one primary key attribute then a primary key class must exist. If there is only one primary key attribute, it cannot have a standard data type, but must have an object data type (ex: java.lang.Long).</p> <p>Manual correction: If there are many primary key attributes, create a primary key class. If there is only one primary key attribute, select an object/classifier data type</p> <p>Automatic correction: Creates a primary key class, or selects the appropriate object/classifier data type</p>

Check	Description and Correction
Class mapping not defined	<p>The class must be mapped to tables or views in the data source.</p> <p>Manual correction: Define the mapping from the Mapping tab of the class property sheet. (Class Sources tab), or remove the data source</p> <p>Automatic correction: Removes the data source from the Mapping For list in the class Mapping tab</p> <p>For more information about O/R mapping, see the "Object to Relational (O/R) mapping" section in <i>Chapter 12, Object Mappings</i> in the <i>Core Features Guide</i>.</p>
Attribute mapping not defined	<p>The attribute must be mapped to columns in the data source.</p> <p>Manual correction: Define the mapping from the Mapping tab of the Class property sheet. (Attributes Mapping tab), or remove the data source</p> <p>Automatic correction: Removes the data source from the Mapping For list in the class Mapping tab</p> <p>For more information about O/R mapping, see the "Object to Relational (O/R) mapping" section in <i>Chapter 12, Object Mappings</i> in the <i>Core Features Guide</i>.</p>
Incomplete bound classifier	<p>A classifier that is of type "Bound" must be bound to a generic classifier.</p> <p>Manual correction: Specify a generic classifier in the field to the right of the type list on the General tab of the bound classifier's property sheet. You can also connect it to the generic classifier by way of a dependency with stereotype <<bind>>.</p> <p>Automatic correction: None</p>
Invalid generation mode	<p>If a class has its persistence mode set to Migrate Columns, it must have a persistent parent or child to which to migrate the columns</p> <p>Manual correction: Link the class to a persistent parent or child, or change its persistence mode on the Detail tab of its property sheet.</p> <p>Automatic correction: None</p>

Identifier Checks

PowerDesigner provides default model checks to verify the validity of identifiers.

Check	Description and Correction
Identifier name and code uniqueness	Identifier names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Existence of attribute	Identifiers must have at least one attribute. Manual correction: Add an attribute to the identifier, or delete the identifier Automatic correction: None
Identifier inclusion	Two identifiers should not use the same attributes. Manual correction: Remove the unnecessary identifier Automatic correction: None

Interface Checks

PowerDesigner provides default model checks to verify the validity of interfaces.

Check	Description and Correction
Interface name and code uniqueness	Interface names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Empty classifier	Attributes and operations are missing for this classifier. Manual correction: Add attributes or operations to the classifier Automatic correction: None
Classifier visibility	A private or protected classifier should be inner to another classifier. Manual correction: Change classifier visibility to public or package Automatic correction: Changes the visibility to public or package

Check	Description and Correction
Interface constructor	<p>An interface cannot be instantiated. Thus a constructor cannot be defined for an interface.</p> <p>Manual correction: Remove the constructor</p> <p>Automatic correction: None</p>
Interface navigability	<p>Navigation is not allowed from an interface.</p> <p>Manual correction: Deselect navigability on the class side of the association</p> <p>Automatic correction: Deselects navigability on the class side of the association</p>
Home interface create methods	<p>The return type for create<METHOD> methods must be the bean component interface type. The throws clause must include the javax.ejb.CreateException together with all exceptions defined in the throws clause of the matching ejbCreate<METHOD> and ejbPostCreate<METHOD> methods of the Bean class.</p> <p>Manual correction: Include the javax.ejb.CreateException and all exceptions defined in the throws clause of the matching ejbCreate<METHOD> and ejbPostCreate<METHOD> methods of the Bean class, or remove exceptions from the ejbPostCreate<METHOD> method</p> <p>Automatic correction: Includes the javax.ejb.CreateException and all exceptions defined in the throws clause of the matching ejbCreate<METHOD> and ejbPostCreate<METHOD> methods of the Bean class</p>
Home interface finder methods	<p>The return type for find<METHOD> methods must be the bean component interface type (for a single-object finder) or a collection of primary keys thereof (for a multi-object finder). The throws clause must include the javax.ejb.FinderException.</p> <p>Manual correction: Include the javax.ejb.FinderException in the throws clause</p> <p>Automatic correction: Includes the javax.ejb.FinderException in the throws clause, and sets Return Type to be the component interface type</p> <p>The following check applies to <i>BPM Entity Beans only</i>.</p> <p>The throws clause must include all exceptions defined in the throws clause of the matching ejbFind<METHOD> methods of the Bean class.</p> <p>Manual correction: Include all exceptions defined in the throws clause of the matching ejbFind<METHOD> methods of the Bean class, or remove exceptions from the ejbFind<METHOD> method</p> <p>Automatic correction: Includes all exceptions defined in the throws clause of the matching ejbFind<METHOD> methods of the Bean class</p>

Check	Description and Correction
Remote Home interface methods	<p>The throws clause of the Remote Home interface methods must include the java.rmi.RemoteException.</p> <p>Manual correction: Include the java.rmi.RemoteException</p> <p>Automatic correction: Includes the java.rmi.RemoteException</p>
Component interface business methods	<p>The throws clause of the component interface business methods must include all exceptions defined in the throws clause of the matching method of the Bean class. The throws clause of the Remote interface methods must include the java.rmi.RemoteException.</p> <p>Manual correction: Include the java.rmi.RemoteException</p> <p>Automatic correction: Includes the java.rmi.RemoteException</p>
Incomplete bound classifier	<p>A classifier that is of type "Bound" must be bound to a generic classifier.</p> <p>Manual correction: Specify a generic classifier in the field to the right of the type list on the General tab of the bound classifier's property sheet. You can also connect it to the generic classifier by way of a dependency with stereotype <<bind>>.</p> <p>Automatic correction: None</p>

Class/Interface Attribute Checks

PowerDesigner provides default model checks to verify the validity of class and interface attributes.

Check	Description and Correction
Attribute name and code uniqueness	<p>Attribute names and codes must be unique in the classifier.</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Inconsistencies within check parameters	<p>The values entered in the check parameters tab are inconsistent for numeric and string data types: default does not respect minimum and maximum values, or default does not belong to list of values, or values in list are not included in minimum and maximum values, or minimum is greater than maximum value. Check parameters must be defined consistently.</p> <p>Manual correction: Modify default, minimum, maximum or list of values in the check parameters tab</p> <p>Automatic correction: None</p>

Check	Description and Correction
Data type assignment	The data type of an attribute should be defined. Moreover, its type cannot be void. Manual correction: Assign a valid data type to the attribute Automatic correction: None
Initial value for final attribute	The final attribute of a classifier must be initialized. Manual correction: Give a default value to the final attribute Automatic correction: None
Domain divergence	The definition of the attribute definition is diverging from the definition of the domain. Manual correction: Modify attribute type to respect domain properties Automatic correction: Corrects attribute type to prevent divergence from domain For more information about domain divergence, see <i>Setting OOM Model Options</i> on page 305.
Event parameter data type	[VB 2005] An interface attribute with a stereotype of Event must have a delegate as its data type. Manual correction: set the data type to an appropriate delegate Automatic correction: None

Class/Interface Operation Checks

PowerDesigner provides default model checks to verify the validity of class and interface operations.

Check	Description and Correction
Operation name and code uniqueness	Operation names and codes must be unique in the classifier. Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Return type assignment	The return type of an operation should be defined. Manual correction: Assign a return type to the operation Automatic correction: Assigns a void return type to the operation

Check	Description and Correction
Parameter data type assignment	<p>The data type of a parameter should be defined. Moreover, its type cannot be void.</p> <p>Manual correction: Choose a valid data type for the parameter</p> <p>Automatic correction: None</p>
Abstract operation body	<p>[classes] Abstract operations in a class cannot be implemented.</p> <p>Manual correction: Remove the body or the abstract property of the operation</p> <p>Automatic correction: None</p>
Abstract operation in a non-abstract class	<p>[classes] Abstract operations must be declared in abstract classes only.</p> <p>Manual correction: Set the class to abstract, or remove the abstract property of the operation</p> <p>Automatic correction: Removes the abstract property in the operation property sheet</p>
Overloading operations signature	<p>[classes] Overloaded operations with the same name and same parameters data type cannot have different return types in a class.</p> <p>Overloading an operation refers to using the same method name but performing different operations based on different parameter number or type.</p> <p>Manual correction: Change the operation name, parameter data type, or return type</p> <p>Automatic correction: None</p>
Overriding operations	<p>[classes] When overriding a parent operation in a class, it is impossible to change its modifiers.</p> <p>Overriding an operation means that an operation defined in a given class is redefined in a child class, in this case the operation of the parent class is said to be overridden.</p> <p>Manual correction: Keep the same modifiers for child operation</p> <p>Automatic correction: None</p>
Enum: Constants must overload abstract method	<p>[classes] You can give each enum constant a different behavior by declaring an abstract method in the enum type and overloading it with a concrete method for each constant. In this case, each constant must overload the abstract method.</p> <p>Manual correction: Make sure each constant is associated with a concrete method that overloads the abstract method.</p> <p>Automatic correction: None</p>

Realization Checks

PowerDesigner provides default model checks to verify the validity of realizations.

Check	Description and Correction
Redundant realizations	Only one realization is allowed between two given objects. Manual correction: Remove redundant realizations Automatic correction: None
Realization generic missing child type parameters	A child of a generic classifier must resolve all of the type parameters defined by its parent. Manual correction: Resolve the missing type parameters. Automatic correction: None.
Realization generic child cannot be bound	A bound classifier cannot be the child of any classifier other than its generic parent. Manual correction: Remove the additional links. Automatic correction: None.

Generalization Checks

PowerDesigner provides default model checks to verify the validity of generalizations.

Check	Description and Correction
Redundant generalizations	Only one generalization is allowed between two classes or two interfaces. Manual correction: Remove redundant generalizations Automatic correction: None
Class multiple inheritance	The following check applies only to <i>Java</i> and <i>PowerBuilder</i> . Multiple inheritance is accepted in UML but not in this language. Manual correction: Keep single inheritance Automatic correction: None
Extend final class	A final class cannot be extended. Manual correction: Remove the generalization link, or remove the final property in the parent class Automatic correction: None

Check	Description and Correction
Non-persistent specifying attribute	<p>If a generalization has a specifying attribute, the attribute must be marked as persistent.</p> <p>Manual correction: Select the Persistent checkbox on the Detail tab of the specifying attribute property sheet.</p> <p>Automatic correction: None</p>
Generalization generic missing child type parameters	<p>A child of a generic classifier must resolve all of the type parameters defined by its parent.</p> <p>Manual correction: Resolve the missing type parameters.</p> <p>Automatic correction: None.</p>
Generalization generic child cannot be bound	<p>A bound classifier cannot be the child of any classifier other than its generic parent.</p> <p>Manual correction: Remove the additional links.</p> <p>Automatic correction: None.</p>

Object Checks

PowerDesigner provides default model checks to verify the validity of objects.

Check	Description and Correction
Object name and code uniqueness	<p>Object names and codes must be unique in the namespace (model or package) if they belong to the same class, or if they do not belong to any class.</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Isolated object	<p>An object should not be isolated in the model.</p> <p>Manual correction: Create a relationship to or from the object. The relationship can be a message, an instance link, or a dependency <i>or</i></p> <p>Link the object to an object node in the activity diagram</p> <p>Automatic correction: None</p> <p>Note: the Check Model feature takes the object into account and not the symbol of the object to perform this check; if the object is already associated with an instance link or an object node in your model, the Check Model feature will not return an error message.</p>

Instance Link Checks

PowerDesigner provides default model checks to verify the validity of instance links.

Check	Description and Correction
Redundant instance links	Two instance links between the same objects should not have the same association. Manual correction: Remove one of the redundant instance links Automatic correction: None

Message Checks

PowerDesigner provides default model checks to verify the validity of messages.

Check	Description and Correction
Message without sequence number	A message should have a sequence number. Manual correction: Enter a sequence number on the message Automatic correction: None
Message used by several instance links	A message should not be attached to several instance links. Manual correction: Detach the message from the instance link Automatic correction: None
Message between actors	An actor cannot send a message to another actor in the model. Messages are allowed between two objects, and between objects and actors. Manual correction: Create a message between two objects or between and actor and an object Automatic correction: None

State Checks

PowerDesigner provides default model checks to verify the validity of states.

Check	Description and Correction
State name and code uniqueness	State names and codes must be unique in the classifier. Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code

Check	Description and Correction
Input transition missing	<p>Each state must have at least one input transition. A state without an input transition cannot be reached.</p> <p>Manual correction: Add a transition linked to the state</p> <p>Automatic correction: None</p>
Composite state does not have any start	<p>A composite state details the state behavior in a sub-statechart diagram. To be complete, this sub-statechart diagram requires a start.</p> <p>Manual correction: Add a start in the sub-statechart diagram, or deselect the Composite check box in the state property sheet</p> <p>Automatic correction: None</p>
Incorrect action order	<p>The entry trigger events must be the first in the list of actions on a state. The exit trigger events must be the last in the list. All other actions can be ordered without any constraint.</p> <p>Manual correction: Move all entry at the top of the list and all exit at the bottom</p> <p>Automatic correction: Moves all entry at the top of the list and all exit at the bottom</p>

State Action Checks

PowerDesigner provides default model checks to verify the validity of state actions.

Check	Description and Correction
Action name and code uniqueness	<p>Action names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Unspecified trigger event	<p>Each action on a state must have a trigger event specified. This trigger event indicates when the action is executed.</p> <p>Note that this check does not apply to actions defined on transitions because transitions have an implicit event corresponding to the end of execution of internal actions (of the source state).</p> <p>Manual correction: Specify a trigger event in the action property sheet</p> <p>Automatic correction: None</p>
Duplicated occurrence	<p>Two distinct actions of a same state should not occur simultaneously. The occurrence of an action is defined by combining a trigger event and a condition.</p> <p>Manual correction: Change the trigger event or the condition of the action</p> <p>Automatic correction: None</p>

Event Checks

PowerDesigner provides default model checks to verify the validity of events.

Check	Description and Correction
Event name and code uniqueness	Event names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Unused event	An event is useful to trigger an action defined on a state or on a transition. An event alone is useless. Manual correction: Delete the event or use it within an action on a state or on a transition Automatic correction: Deletes the event

Junction Point Checks

PowerDesigner provides default model checks to verify the validity of junction points.

Check	Description and Correction
Junction point name and code uniqueness	Junction point names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Incomplete junction point	A junction point represents a split or a merge of transition paths. That is why a junction point must have at least one input and one output transitions. Manual correction: Add any missing transitions on the junction point Automatic correction: None

Activity Checks

PowerDesigner provides default model checks to verify the validity of activities.

Check	Description and Correction
Activity name and code uniqueness	Activity names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code
Input or Output transition missing	Each activity must have at least one input transition and at least one output transition. Manual correction: Add a transition linked to the activity Automatic correction: None
Composite activity does not have any start	A composite activity details the activity execution in a sub-activity diagram. To be complete, this sub-activity diagram requires a start connected to other activities, or requires a start at the beginning. Manual correction: Add a start in the sub-activity diagram, or deselect the Composite check box in the activity property sheet Automatic correction: None
Non-Reusable Activity Calls	Only activities with an action type of <undefined> or Reusable activity may be reused by other activities with action types of Call, Accept Call, or Reply Call. Manual correction: Change the action type of the referenced activity, or remove any references to it. Automatic correction: None

Decision Checks

PowerDesigner provides default model checks to verify the validity of decisions.

Check	Description and Correction
Decision name and code uniqueness	Decision names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code

Check	Description and Correction
Incomplete decision	<p>A decision represents a conditional branch when a unique transition is split into several output transitions, or it represents a merge when several input transitions are merged into a unique output transition. That is why a decision must have more than one input transition or more than one output transition.</p> <p>Manual correction: Add any missing transitions on the decision</p> <p>Automatic correction: None</p>

Object Node Checks

PowerDesigner provides default model checks to verify the validity of object nodes.

Check	Description and Correction
Object node name and code uniqueness	<p>Object node names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Object node with undefined object	<p>An object node represents a particular state of an object. That is why an object must be linked to an object node.</p> <p>Manual correction: In the property sheet of the object node, select or create an object from the Object list</p> <p>Automatic correction: None</p>
Object Node Without Data Type	<p>An object node conveys no information if it does not have a data type.</p> <p>Manual correction: Select a Data type in the object node property sheet.</p> <p>Automatic correction: None</p>

Organization Unit Checks

PowerDesigner provides default model checks to verify the validity of organization units.

Check	Description and Correction
Organization unit name and code uniqueness	<p>Organization unit names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>

Check	Description and Correction
Circular dependency	<p>The organization unit cannot be parent of itself or parent of another child organization unit.</p> <p>Manual correction: Change the organization unit in the Parent box in the organization unit property sheet</p> <p>Automatic correction: None</p>

Start/End Checks

PowerDesigner provides default model checks to verify the validity of starts and ends.

Check	Description and Correction
Start/end name and code uniqueness	<p>Start and end names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Missing transition	<p>Starts and ends must be linked to an object of the statechart or activity diagram.</p> <p>Manual correction: Create a transition from the start and/or to the end</p> <p>Automatic correction: None</p>

Synchronization Checks

PowerDesigner provides default model checks to verify the validity of synchronizations.

Check	Description and Correction
Synchronization name and code uniqueness	<p>Synchronization names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Incomplete synchronization	<p>A synchronization represents a fork when a unique transition is split into several output transitions executed in parallel, or it represents a join when several input transitions are joined and they wait until all transitions reach the join before continuing as a unique output transition. That is why a synchronization must have more than one input transition, or more than one output transition.</p> <p>Manual correction: Add any missing transitions to the synchronization</p> <p>Automatic correction: None</p>

Transition and Flow Checks

PowerDesigner provides default model checks to verify the validity of transitions and flows.

Check	Description and Correction
Transition / flow without source or destination	The transition or flow has no source or destination. Manual correction: Select or create an object as source or destination. Automatic correction: None
Useless condition	If there is only one output transition/flow, there is no reason to have a condition or type on the transition/flow. Manual correction: Remove the unnecessary condition or type, or create another transition/flow with another condition or type. Automatic correction: None
Missing condition	If an object has several output transitions/flows, or if the transition/flow is reflexive, each transition/flow must contain a condition. In a statechart diagram, a transition must contain an event or condition. Manual correction: Define a condition, or create a synchronization to specify a parallel execution Automatic correction: None
Duplicated transition between states/ Duplicated flow between activities	Two parallel transitions (with the same extremities) must not occur simultaneously, but must rather be governed by conditions (and, for transitions, trigger events). Manual correction: Change one of the trigger events or conditions Automatic correction: None

Component Checks

PowerDesigner provides default model checks to verify the validity of components.

Check	Description and Correction
Component name and code uniqueness	Component names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code

Check	Description and Correction
Isolated component	<p>A component should not be isolated in the model. It should be linked to a class or an interface.</p> <p>Manual correction: Attach some classes or interfaces to the component</p> <p>Automatic correction: None</p>
EJB component attached classifiers	<p>Entity and Session Beans must provide either a remote or a local client view, or both.</p> <p>Manual correction: Complete existing view(s), or create a remote view if no interface has been exposed</p> <p>Automatic correction: Completes existing view(s), or creates a remote view if no interface has been exposed</p>
SOAP message re-definition	<p>You cannot have the same SOAP input and SOAP output data type inside the same component.</p> <p>Manual correction: Change the name of the input data type, or change the name of the output data type in the SOAP Input or SOAP Output tabs in the operation property sheet</p> <p>Automatic correction: None</p> <p>The definition of the SOAP data types is available in the schema part of the WSDL that you can display in the WSDL tab of the component property sheet.</p>

Node Checks

PowerDesigner provides default model checks to verify the validity of nodes.

Check	Description and Correction
Node name and code uniqueness	<p>Node names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Empty node	<p>A node is said to be empty when it does not contain any component instance.</p> <p>Manual correction: Add at least one component instance to the node</p> <p>Automatic correction: None</p>

Component Instance Checks

PowerDesigner provides default model checks to verify the validity of component instances.

Check	Description and Correction
Component instance name and code uniqueness	<p>Component instance names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Component instance without component	<p>An instance of a component has been created but no component is attached. You must attach it to a component.</p> <p>Manual correction: Attach an existing component to the component instance, or create a component from the Create tool in the property sheet of the component instance</p> <p>Automatic correction: None</p>
Duplicate component instances	<p>Several instances of the same component exist in the same node.</p> <p>Manual correction: Delete the duplicate component instance or attach it to the right component</p> <p>Automatic correction: None</p>
Isolated component instance	<p>A component instance should not be created outside of a node. It will not be deployed.</p> <p>Manual correction: Attach it to a node</p> <p>Automatic correction: None</p>

Interaction Reference Checks

PowerDesigner provides default model checks to verify the validity of interaction references.

Check	Description and Correction
Interaction reference missing referenced diagram	<p>An interaction reference object must reference a sequence diagram object.</p> <p>Manual correction: Open the interaction reference property sheet and specify the sequence diagram to reference.</p> <p>Automatic correction: None</p>

Check	Description and Correction
Interaction reference attached lifelines consistency	<p>The interaction reference symbol has a list of attached lifelines, which correspond to actors and objects. These actors and objects must match a subset of the ones displayed in the referenced sequence diagram. This corresponds to a subset because some lifelines in referenced diagram could not be displayed in the diagram of the interaction reference. The current check verifies the following consistency rules:</p> <p>The number of attached lifelines cannot be greater than the number of lifelines in the referenced diagram</p> <p>If one attached lifeline corresponds to an object, and if this object has an associated metaclass, then there must be at least one object in the referenced sequence diagram that is associated with the same metaclass</p> <p>Manual correction: Change the list of attached lifelines for the interaction reference object. This can be done simply by resizing the interaction reference symbol or by clicking with the pointer tool on the intersection of the interaction reference symbol and the lifeline. The tool cursor changes on this area and allows you to detach the interaction reference symbol from (or attach it to) the lifeline.</p> <p>Automatic correction: None</p>
Too many input messages for reference	<p>The interaction reference has more incoming than outgoing messages.</p> <p>Manual correction: Delete incoming messages or add outgoing messages, until the numbers are equal.</p> <p>Automatic correction: None</p>
Too many output messages for reference	<p>The interaction reference has more outgoing than incoming messages.</p> <p>Manual correction: Delete outgoing messages or add incoming messages, until the numbers are equal.</p> <p>Automatic correction: None</p>

Class Part Checks

PowerDesigner provides default model checks to verify the validity of class parts.

Check	Description and Correction
Class part name and code uniqueness	<p>Class part names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>

Check	Description and Correction
Class part classifier type	<p>A class part must have a data type that is a classifier linked to its owner classifier by an association.</p> <p>Manual correction: Specify a data type for the part and connect the relevant classifier to its owner classifier.</p> <p>Automatic correction: None</p>
Class part association type	<p>The composition property of a part must match the type of the association between its owner and its data type.</p> <p>Manual correction: Enable or disable the Composition property.</p> <p>Automatic correction: The Composition property is enabled or disabled.</p>

Class/Component Port Checks

PowerDesigner provides default model checks to verify the validity of class and component ports.

Check	Description and Correction
Class or component port name and code uniqueness	<p>Class and component port names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>
Class or component port isolated ports	<p>Class and component ports must have a data type, or must have a provided or required interface.</p> <p>Manual correction: Specify a data type or interface</p> <p>Automatic correction: None</p>

Class/component Assembly Connector Checks

PowerDesigner provides default model checks to verify the validity of class and component assembly connectors.

Check	Description and Correction
Component assembly connector name and code uniqueness	<p>Class and component assembly connector names and codes must be unique in the namespace (model or package).</p> <p>Manual correction: Modify the duplicate name/code</p> <p>Automatic correction: Appends a number to the duplicate name/code</p>

Check	Description and Correction
Component assembly connector null interface connector	An interface must be defined for each assembly connector. Manual correction: Define an interface for the assembly connector. Automatic correction: None.
Component assembly connector interfaces	The interface defined for an assembly connector must be provided by the supplier and required by the client. Manual correction: Ensure that the supplier and client are correctly defined. Automatic correction: None.

Association Checks

PowerDesigner provides default model checks to verify the validity of associations.

Check	Description and Correction
Association generic missing child type parameters	In a navigable association, if the parent is generic, the child must redefine all the type parameters of the parent. If the parent is a partially bound classifier (where some type parameters are not resolved) then the child must redefine all the unresolved type parameters. Manual correction: Resolve the missing type parameters. Automatic correction: None.
Association generic child cannot be bound	A bound classifier cannot be the child of any navigable association other than its generic parent. Manual correction: Remove the additional links. Automatic correction: None.

Activity Input and Output Parameter Checks

PowerDesigner provides default model checks to verify the validity of activity input and output parameters.

Check	Description and Correction
Input/output parameter name and code uniqueness	Activity input and output parameter names and codes must be unique in the namespace (model or package). Manual correction: Modify the duplicate name/code Automatic correction: Appends a number to the duplicate name/code

CHAPTER 11 Importing a Rational Rose Model into an OOM

You can import Rational Rose (.MDL) models created with version 98, 2000, and 2002 into an OOM.

A Rose model can support one or several languages whereas a PowerDesigner OOM can only have a single object language. When you import a multi-language Rose model into an OOM, the OOM will have only one of the object languages of the Rose model.

The following table shows how Rose languages are converted to PowerDesigner languages:

Rose Language	PowerDesigner Language
CORBA	IDL-CORBA
Java	Java
C++	C++
VC++	C++
XML-DTD	XML-DTD
Visual Basic	Visual Basic 6
Analysis, Oracle 8, Ada, COM, Web Modeler, and all other languages	Analysis

1. Select **File > Import > Rational Rose File**, and browse to the directory that contains the Rose file.
2. Select Rational Rose Model (*.MDL) file from the Files of Type list, and then select the file to import.
3. Click Open.

The import process begins, and the default diagram of the model opens in the canvas.

Importing Rational Rose General Objects

Rose general objects are imported as follows.

Rose Object	OOM Object
Package	Package

Rose Object	OOM Object
Diagram	<ul style="list-style-type: none"> Diagram
Note	Note
<ul style="list-style-type: none"> Note link Note link Text Text File File 	<ul style="list-style-type: none"> Note link Text Text File File
<ul style="list-style-type: none"> Text Text File File 	<ul style="list-style-type: none"> Text File File
<ul style="list-style-type: none"> File File 	<ul style="list-style-type: none"> File

Only the following properties are imported for these objects:

Rose Property	OOM Property
Documentation	Comment
Zoom	<ul style="list-style-type: none"> Page scale
Stereotype	Stereotype

Importing Rational Rose Use Case Diagrams

Objects in Rose use case diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Class with <<actor>>, <<business actor>>, or <<business worker>> stereotype	Implementation class contained by an actor
Class with <<boundary>>, <<business entity>>, <<control>>, <<entity>>, or <<table>> stereotype	Class (without symbol, as classes are not permitted in OOM use case diagrams)

Rose Object	OOM Object
Use case: <ul style="list-style-type: none"> • Diagrams 	Use case: <ul style="list-style-type: none"> • Related diagrams
Association: <ul style="list-style-type: none"> • Navigable 	Association: <ul style="list-style-type: none"> • Orientation

Note that dependencies between a use case and an actor are not imported.

Importing Rational Rose Class Diagrams

Objects in Rose class diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Class: <ul style="list-style-type: none"> • 'Class utility' Type • Export Control • Implementation • Cardinality: 0..n, 1..n • Nested class • Persistence • Abstract 	Class: <ul style="list-style-type: none"> • 'Class' Type • Visibility • Package • Cardinality: 0..*, 1..* • Inner classifier • Persistence • Abstract
Interface: <ul style="list-style-type: none"> • Export Control • Implementation • Nested class 	Interface: <ul style="list-style-type: none"> • Visibility • Package • Inner classifier
Attribute: <ul style="list-style-type: none"> • Export Control • Implementation • Initial value • Static • Derived 	Attribute: <ul style="list-style-type: none"> • Visibility • Package • Initial value • Static • Derived
Operation: <ul style="list-style-type: none"> • Export Control • Implementation 	Operation: <ul style="list-style-type: none"> • Visibility • Package

Rose Object	OOM Object
Generalization: <ul style="list-style-type: none"> • Export Control • Implementation • Virtual inheritance • Multi inheritance 	Generalization: <ul style="list-style-type: none"> • Visibility • Package • Extended attribute • Multi inheritance
Association: <ul style="list-style-type: none"> • Role name • Export Control • Navigable • Cardinality • Aggregate (class A or B) • Aggregate (by reference) • Aggregate (by value) 	Association: <ul style="list-style-type: none"> • Role name • Visibility • Navigable • Multiplicity • Container • Aggregation • Composition
Dependency	Dependency

Importing Rational Rose Collaboration Diagrams

Objects in Rose collaboration diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Object or class instance: <ul style="list-style-type: none"> • Class • Multiple instances 	Object: <ul style="list-style-type: none"> • Class or interface • Multiple
Link or object link: <ul style="list-style-type: none"> • Assoc • Messages list 	Instance link: <ul style="list-style-type: none"> • Association • Messages
Actor	Actor
Message: <ul style="list-style-type: none"> • Simple stereotype • Synchronous stereotype • Asynchronous stereotype • Balking 	Message: <ul style="list-style-type: none"> • Undefined • Procedure call • Asynchronous • Condition

Importing Rational Rose Sequence Diagrams

Objects in Rose sequence diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Object or class instance: <ul style="list-style-type: none"> • Persistence • Multiple instances 	Object: <ul style="list-style-type: none"> • Persistence • Multiple
Actor	Actor
Message: <ul style="list-style-type: none"> • Simple stereotype • Synchronous stereotype • Asynchronous stereotype • Balking • Return message • Destruction marker 	Message: <ul style="list-style-type: none"> • Undefined • Procedure call • Asynchronous • Condition • Return • Recursive message with Destroy action

Importing Rational Rose Statechart Diagrams

In Rose, activity and statechart diagrams are created in the Use Case or Logical View:

- At the root level
- In an activity
- In a state

A UML State Machine is automatically created, which contains statechart and activity diagrams with their relevant objects.

In PowerDesigner, statechart diagrams are created at the model level or in a composite state: the parent package or the model is considered the State Machine.

Rose statechart diagrams that are at the root level, or in a state are imported, but those that are in an activity are not imported.

Objects in Rose statechart diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
State: <ul style="list-style-type: none"> • When action • OnEntry action • OnExit action • Do action • OnEvent action • Event action • Event arguments 	State or object node: <ul style="list-style-type: none"> • Trigger event • Entry • Exit • Do • Event • Trigger event • Event arguments
State transition: <ul style="list-style-type: none"> • <No name> • <No code> • Event • Arguments • Guard condition • Action 	Transition: <ul style="list-style-type: none"> • Calculated name • Calculated Code • Trigger Event • Event arguments • Condition • Trigger action

Importing Rational Rose Activity Diagrams

Objects in Rose activity diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Activity: <ul style="list-style-type: none"> • Actions 	Activity: <ul style="list-style-type: none"> • Action
Object (associated with a state)	Object node
State	State (no symbol in activity diagram)
Start state	Start
Self Transition or Object Flow	Transition
Synchronization	Synchronization
Decision	Decision
End state	End
Swimlane	Organization unit/swimlane

Notes:

- PowerDesigner does not support multiple actions on an activity. After import, the Action tab in the OOM activity property sheet displays <<Undefined>> and the text zone reproduces the list of imported actions.
- PowerDesigner does not manage Rose Subunits as separate files, but rather imports *.CAT and *.SUB files into the model that references them. If a .CAT or a .SUB file does not exist in the specified path, PowerDesigner searches in the same directory as the file containing the model.
- In Rose, you can associate an Object (instance of a class) with a State. The Rose Object is imported as an object without symbol. If it is associated with a State, an object node with a symbol is created with the name, stereotype and comment of the State. If the Rose diagram that contains the symbol of the Object is in a composite activity, a shortcut of the object is created in the imported composite activity, because PowerDesigner does not support decomposition of object nodes.

Importing Rational Rose Component Diagrams

Objects in Rose component diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Component: <ul style="list-style-type: none"> • Interface of realize • Class of realize • File • URL file • Declaration 	Component: <ul style="list-style-type: none"> • Interface • Class • External file in Ext. Dependencies • URL file in Ext. Dependencies • Description in Notes tab

The following types of components, which have Rose predefined stereotypes and different symbols are imported. The stereotypes are preserved, but each will have a standard OOM component symbol:

- Active X
- Applet
- Application
- DLL
- EXE
- Generic Package
- Generic Subprogram
- Main Program
- Package Body
- Package Specification

- Subprogram Body
- Subprogram Specification
- Task Body
- Task Specification

Importing Rational Rose Deployment Diagrams

Objects in Rose deployment diagrams are imported as follows. Only the listed properties are imported:

Rose Object	OOM Object
Node: <ul style="list-style-type: none"> • Device • Processor • Device characteristics • Processor characteristics 	Node: <ul style="list-style-type: none"> • Node • Node • Description • Description
File objects: <ul style="list-style-type: none"> • File • URL definition 	File objects: <ul style="list-style-type: none"> • File object linked to the package • File object
Node association: <ul style="list-style-type: none"> • Connection • Characteristics 	Node association: <ul style="list-style-type: none"> • Node association • Description

CHAPTER 12 Importing and Exporting an OOM in XMI Format

PowerDesigner supports the import and export of XML Metadata Interchange (XMI) UML v2.x files, an open format that allows you to transfer UML models between different tools. All of the OOM objects can be imported and exported.

Importing XMI Files

PowerDesigner supports the import of an OOM from an XMI file. Since XMI only supports the transfer of objects, PowerDesigner assigns default symbols to imported objects and assigns them to default diagrams.

1. Select **File > Import > XMI File** to open the New Model dialog.
2. Select an object language, specify the first diagram in the model and click OK.
3. Select the .XML or .XMI file to import and click **Open**.

The General tab in the Output window shows the objects being imported. When the import is complete, your specified first diagram opens in the canvas.

Exporting XMI Files

PowerDesigner supports the export of an OOM to an XMI file. Since XMI only supports the transfer of objects, any associated PowerDesigner symbols and diagrams are not preserved during the export.

PowerDesigner exports to UML container objects as follows:

UML Container	PowerDesigner Object	PowerDesigner Diagram
Activity	Composite Activity	Activity Diagram
State Machine	Composite State	State Diagram
Interaction	Package	Sequence Diagram, Communication Diagram, or Interaction Overview Diagram

1. Select **File > Export > XMI File** to open a standard Save As dialog box.

2. Enter a filename for the file to be exported, select the appropriate type, and click Save.

The General tab in the Output window shows the objects being exported. You can open the resulting XMI file in any modeling tool that supports this exchange format or a code generator such as Java, CORBA, or C++.

PART III

OOM Target Reference

The chapters in this part provide information specific to the target object languages supported by PowerDesigner.

CHAPTER 13 Working with Java

PowerDesigner supports the modeling of Java programs including round-trip engineering.

Note: To model for Java v5 and higher, select Java as your target language. For earlier versions, select Java 1.x.

For information specific to modeling for Java in the Eclipse environment, see the "Working with the PowerDesigner Plugin for Eclipse" chapter in the *Core Features Guide*.

Java Public Classes

Java allows the creation of multiple classes in a single file but one class, and only one, has to be public.

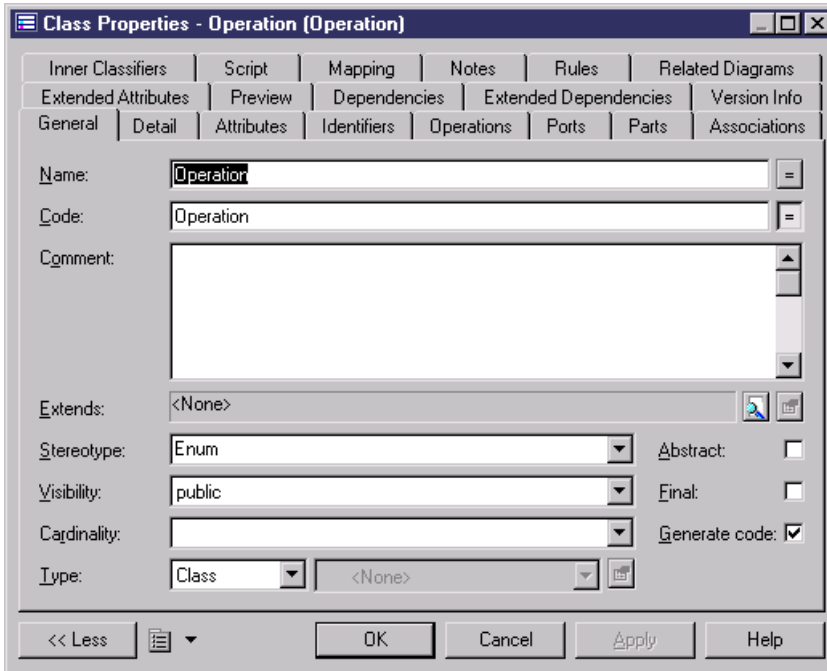

In PowerDesigner, you should create one public class and several dependent classes and draw dependency links with stereotype <<sameFile>> between them. This type of link is handled during generation and reverse engineering.

Java Enumerated Types (Enums)

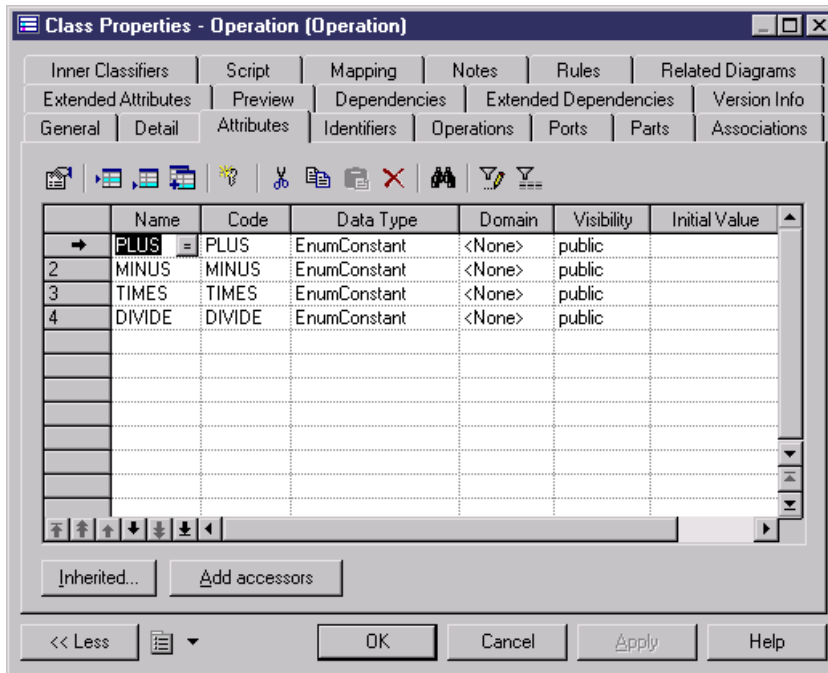

Java 5 supports enumerated types. These replace the old typesafe enum pattern, and are much more compact and easy to maintain. They can be used to list such collections of values as the days of the week or the suits of a deck of cards, or any fixed set of constants, such as the elements in a menu.

An enum is represented by a class with an <<enum>> stereotype.

1. Create a class in a class diagram or composite structure diagram, and double-click it to open its property sheet.
2. On the General tab, select <<enum>> from the Stereotype list.

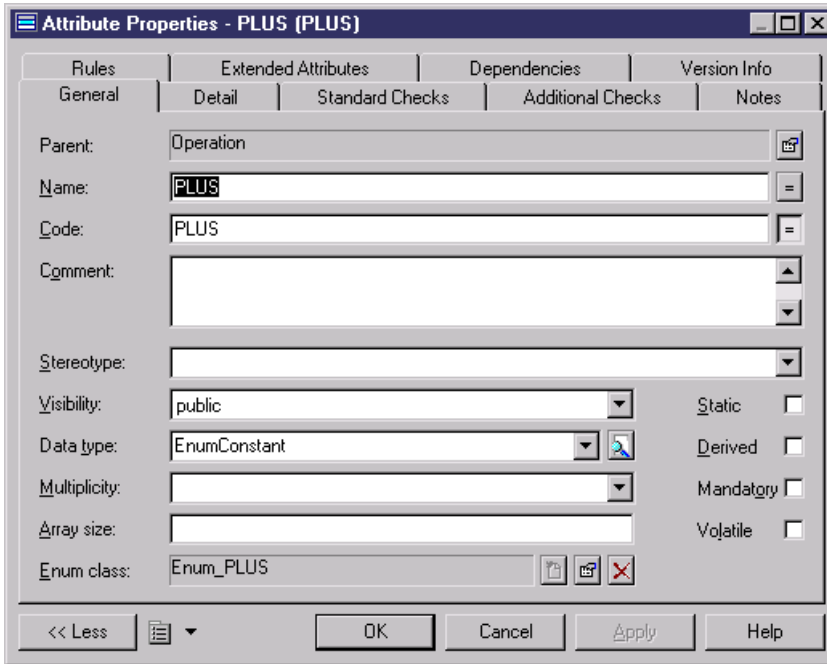

3. Click the Attributes tab, and add as many attributes as necessary. These attributes have, by default, a data type of EnumConstant. For example, to create an enum type that contained standard mathematical operations, you would create four EnumConstants with the names "PLUS", "MINUS", "TIMES", and "DIVIDE".

Note that, since a Java enum is a full featured class, you can also add other kinds of attributes to it by clicking in the Data Type column and selecting another type from the list.

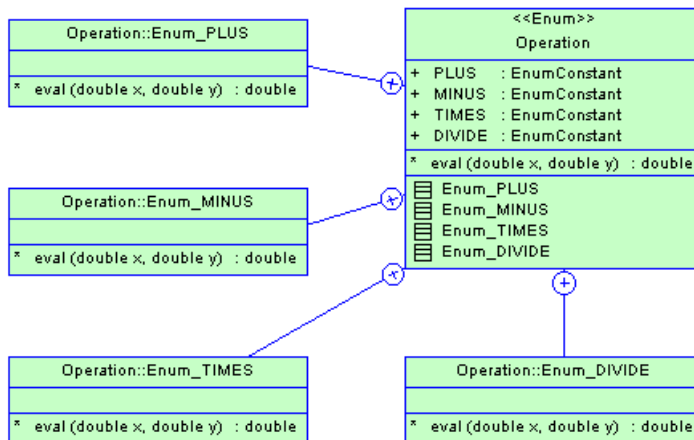

4. [optional] You can create an anonymous class for an EnumConstant by selecting its row on the Attributes tab and clicking the Properties tool to open its property sheet. On the General tab, click the Create tool next to the Enum class box to create the internal class.

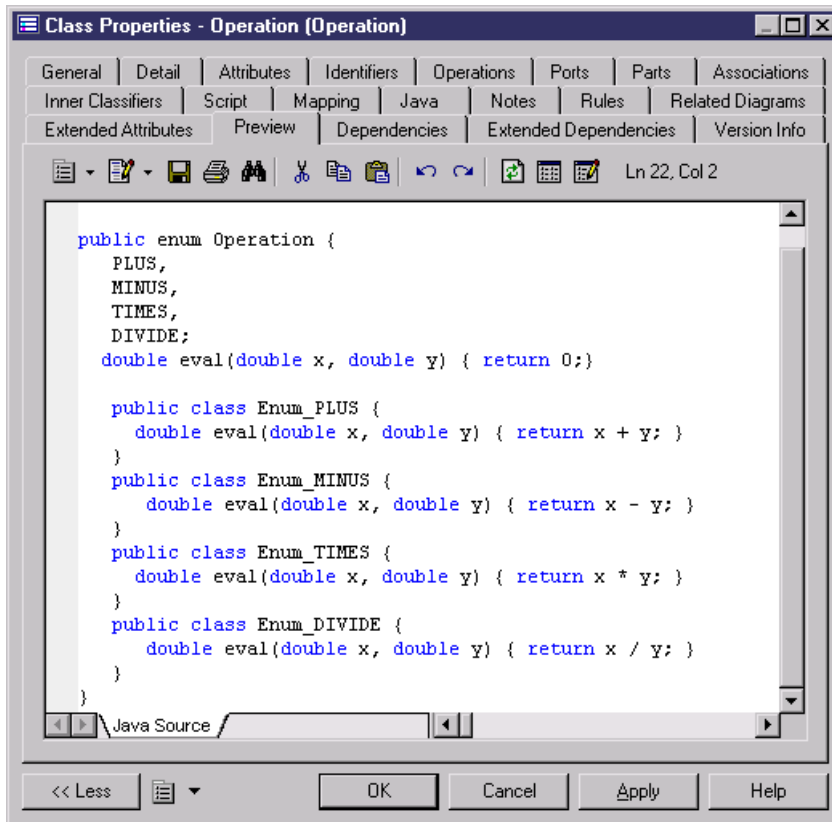

These anonymous classes will be displayed on the Inner Classifiers tab of the Enum class property sheet:

The Operation enum class, with an anonymous class for each of its EnumConstants to allow for the varied arithmetic operations, could be represented in a class diagram as follows:

The equivalent code would be like the following:

JavaDoc Comments

Javadoc is a tool delivered in the JDK that parses the declarations and documentation comments in a set of Java source files and produces a corresponding set of HTML pages describing model objects.

Javadoc comments are included in the source code of an object, immediately before the declaration of any object, between the characters `/**` and `*/`.

A Javadoc comment can contain:

- A description after the starting delimiter `/**`. This description corresponds to a Comment in OOM objects
- Tags prefixed by the `@` character

For example, in the following code preview page, you can read the tag `@author`, and the comment inserted from the Comment box in the General page of the class property sheet.

The following table summarizes the support of Javadoc comments in PowerDesigner:

Javadoc	Description	Applies to	Corresponding extended attribute
%comment%	Comment box. If Javadoc comments are not found, standard comments are reversed instead	Class, interface, operation, attribute	—
@since	Adds a "Since" heading with the specified since-text to the generated documentation	Class, interface, operation, attribute	Javadoc since
@deprecated	Adds a comment indicating that this API should no longer be used	Class, interface, operation, attribute	Javadoc deprecated

Javadoc	Description	Applies to	Corresponding extended attribute
@author	Adds an Author entry	Class, interface	Javadoc author. If the tag is not defined, the user name from the Version Info page is used, otherwise the defined tag value is displayed
@version	Adds a Version entry, usually referring to the version of the software	Class, interface	Javadoc version
@see	Adds a "See Also" heading with a link or text entry that points to reference	Class, interface, operation, attribute	Javadoc see
@return	Adds a "Returns" section with the description text	Operation	Javadoc misc
@throws	Adds a "Throws" subheading to the generated documentation	Operation	Javadoc misc. You can declare operation exceptions
@exception	Adds an "Exception" subheading to the generated documentation	Operation	Javadoc misc. You can declare operation exceptions
@serialData	Documents the types and order of data in the serialized form	Operation	Javadoc misc
@serialField	Documents an ObjectOutputStreamField component of a Serializable class' serialPersistentFields member	Attribute	Javadoc misc
@serial	Used in the doc comment for a default serializable field	Attribute	Javadoc misc

Javadoc	Description	Applies to	Corresponding extended attribute
@param	Adds a parameter to the Parameters section	Attribute	Javadoc misc

Defining Values for Javadoc Tags

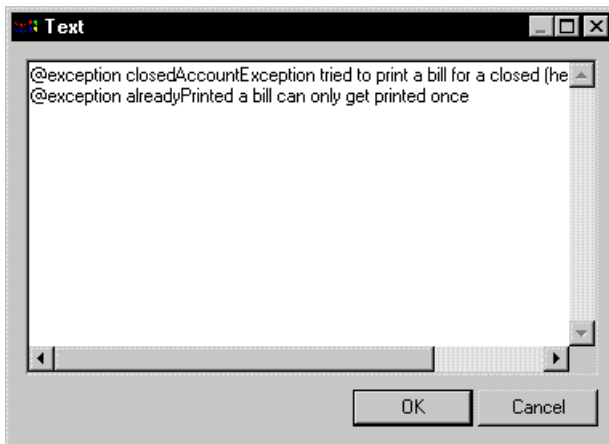

You can define values for Javadoc tags from the Javadoc tab of an object property sheet.

To do so, you have to select a Javadoc tag in the list of extended attributes and click the ellipsis button in the Value column. The input dialog box that is displayed allows you to create values for the selected Javadoc tag. For example, if the data type is set to (Color), you can select another color in the Color dialog box by clicking the ellipsis button in the Value column.

Note: You define values for the @return, @exception, @throws, @serialData, @serialField, @serial JavaDoc, and @param comments in the Javadoc@misc extended attribute.

Javadoc tags are not generated if no extended attribute is valued.

Do not forget to repeat the Javadoc tag before each new value, some values being multi-line. If you do not repeat the Javadoc tag, the values will not be generated.

When you assign a value to a Javadoc tag, the tag and its value appear in the code preview page of the corresponding object.

@author

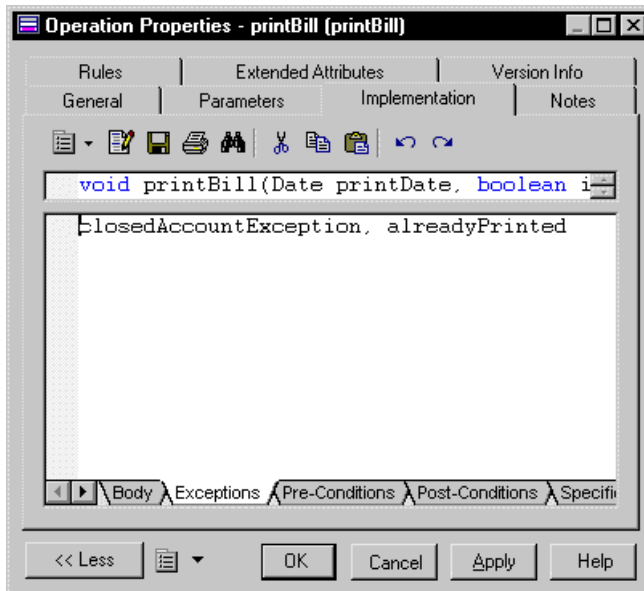

@author is not generated if the extended attribute has no value.

@exceptions and @throws

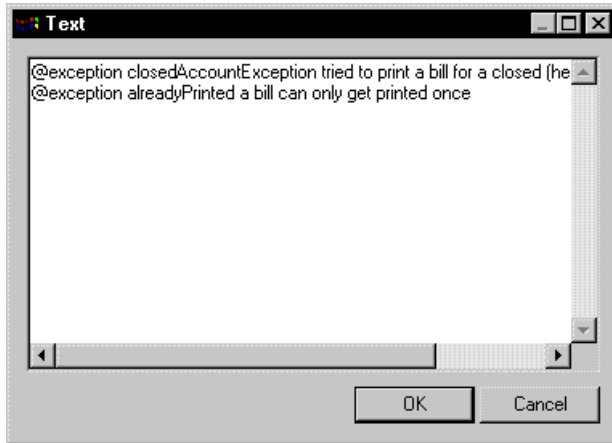

@exceptions and @throws are synonymous Javadoc tags used to define the exceptions that may be thrown by an operation.

To use these tags you can proceed as follows:

- From the operation property sheet, click the Implementation tab and click the Exceptions tab to open the Exceptions page. You can type exceptions in this page.

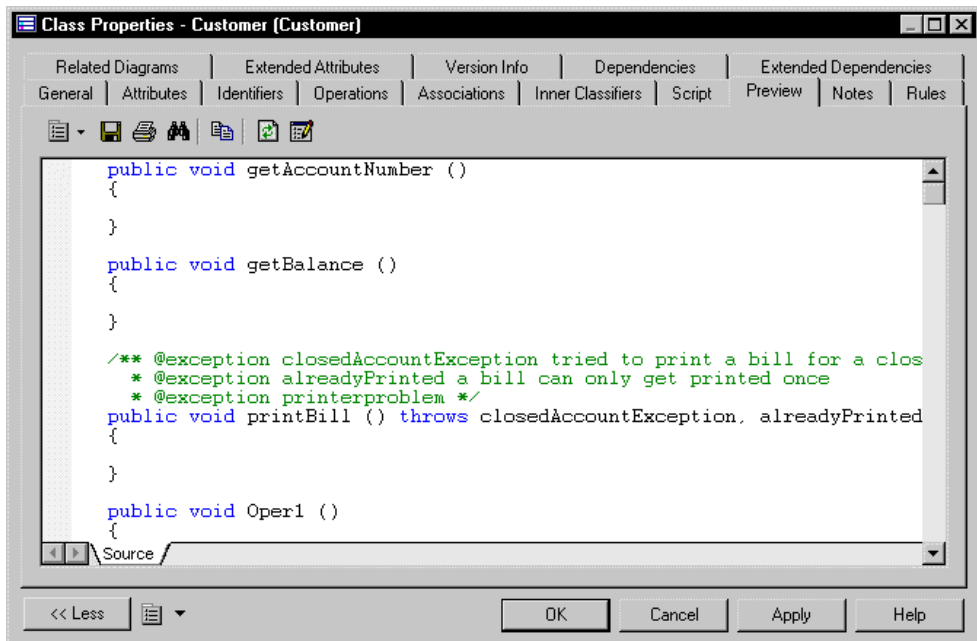

- In the same property sheet, click the Extended Attributes tab, select the Javadoc@exception line in the list and click the ellipsis button in the Value column. Type values for each declared exception, do not forget to repeat @exception or @throws before each exception.

It is also possible to type values directly after the `@exception` or the `@throws` tags in the Extended Attributes page. These comments describe exceptions that are not listed in the operation exceptions, and do not appear after the `throws` parameter in the Preview page of the class.

When you preview the generated code, each exception is displayed with its value:

Javadoc Comments Generation and Reverse Engineering

You recover Javadoc comments in classes, interfaces, operations, and attributes during reverse engineering. Javadoc comments are reverse engineered only if they exist in the source code.

The Reverse Javadoc Comments feature is very useful for *round-trip engineering*: you keep Javadoc comments during reverse engineering and you can regenerate the code with preserved Javadoc comments. The generation process generates object comments compliant with Javadoc

For more information on the generation of Javadoc comments, see *Javadoc Comments Generation and Reverse Engineering* on page 364.

Java 5.0 Annotations

PowerDesigner provides full support for Java 5.0 annotations, which allow you to add metadata to your code. This metadata can be accessed by post-processing tools or at run-time to vary the behavior of the system.

You can use built-in annotations, such as those listed below, and also create your own annotations, to apply to your types.

There are three types of annotations available:

- Normal annotations – which take multiple arguments
- Single member annotations – which take only a single argument, and which have a more compact syntax
- Marker annotations – which take no parameters, and are used to instruct the Java compiler to process the element in a particular way

PowerDesigner supports the seven built-in Java 5.0 annotations:

- `java.lang.Override` - specifies that a method declaration will override a method declaration in a superclass, and will generate a compile-time error if this is not the case.
- `java.lang.Deprecated` – specifies that an element is deprecated, and generates a compile-time warning if it is used in non-deprecated code.
- `java.lang.SuppressWarning` – specifies compile-time warnings that should be suppressed for the element.
- `java.lang.annotation.Documented` – specifies that annotations with a type declaration are to be documented by javadoc and similar tools by default to become part of the public API of the annotated elements.
- `java.lang.annotation.Inherited` – specifies that an annotation type is automatically inherited for a superclass
- `java.lang.annotation.Retention` – specifies how far annotations will be retained during processing. Takes one of the following values:

- SOURCE – annotations are discarded at compile-time
- CLASS – [default] annotations are retained by the compiler, but discarded at run-time
- RUNTIME – annotations are retained by the VM at run-time
- java.lang.annotation.Target – restricts the kind of program element to which an annotation may be applied and generates compile-time errors. Takes one of the following values:
 - TYPE – class, interface, or enum declaration
 - FIELD – including enum constants
 - METHOD
 - PARAMETER
 - CONSTRUCTOR
 - LOCAL_VARIABLE
 - PACKAGE

For general information about modeling this form of metadata in PowerDesigner, see *Attributes (OOM)* on page 65.

Java Strictfp Keyword

Floating-point hardware may calculate with more precision and with a greater range of values than required by the Java specification. The strictfp keyword can be used with classes or operations in order to specify compliance with the Java specification (IEEE-754). If this keyword is not set, then floating-point calculations may vary between environments. To enable the Strictfp keyword:

1. Double-click a class to open its property sheet.
2. Click the Extended Attributes tab, and then click the Java sub-tab.
3. Find the strictfp entry in the Name column, and set the Value to "true".
4. Click OK. The class will be generated with the strictfp keyword, and will perform operations in compliance with the Java floating-point specification

Enterprise Java Beans (EJBs) V2

The Java™ 2 Platform, Enterprise Edition (*J2EE™*) is a Java platform that defines the standard for developing multi-tier enterprise applications. J2EE simplifies enterprise applications by basing them on standardized, reusable modular components, it provides a complete set of services to those components, and handles many details of application behavior automatically without complex programming.

Java 2 Enterprise Edition supports the following technologies that you can use in PowerDesigner:

- Enterprise JavaBean (EJB)

- Java Servlets (Servlets)
- Java Server Page (JSP)

The following sections develop how to use these technologies in PowerDesigner.

EJB

Sun Microsystems definition of Enterprise JavaBeans TM is:

"The Enterprise JavaBeans architecture is a component architecture for the development and deployment of component-based distributed business applications. Applications written using the Enterprise JavaBeans architecture are scalable, transactional and multi-user secure. These applications may be written once and then deployed on any server platform that supports the Enterprise JavaBeans specification".

EJBs are non-visual, remotely executable components that can be deployed on a server, they provide a component architecture framework for creating distributed n-tier middleware. They communicate with clients to make some services available to them.

Enterprise JavaBeans enable rapid and simplified development of distributed, transactional, secure, and portable Java applications. EJB servers reduce the complexity of developing middleware by providing automatic support for middleware services such as transactions, security and database connectivity.

For more information on EJB, a specification is available from Sun Web site, at <http://java.sun.com>.

PowerDesigner supports the EJB 2.0 specification, with special emphasis on entity beans (both CMP and BMP). PowerDesigner implementation of EJB support can take full advantage of the tight integration between PDM and OOM.

What Do You Need to Work with EJBs?

You need Java 2 SDK Standard Edition (J2SE TM) 1.3 (final release), Java 2 SDK Enterprise Edition (J2EE TM) 1.3 (final release), a Java IDE or a text editor. You also need a J2EE application server supporting EJB 2.0.

It is also recommended that you set up the JAVA_HOME and J2EE_HOME system variables in your environment as follows:

In CLASSPATH:

```
%JAVA_HOME%\lib;%J2EE_HOME%\lib\j2ee.jar;%J2EE_HOME%\lib
```

In Path:

```
%JAVA_HOME%\bin;%J2EE_HOME%\bin
```

Using EJB Types

You can define the following types of EJB components:

Type	Definition
Entity Beans	Designed to represent data in the database; they wrap data with business object semantics, read and update data automatically. Entity beans include: <i>CMP (Container Managed Persistence)</i> With CMP Entity Beans, persistence is handled by the component server (also known as Container) <i>BMP (Bean Managed Persistence)</i> With BMP Entity Beans, persistence management is left to the bean developer
<i>Session Beans</i> (Stateful and Stateless)	Encapsulate business logic and provide a single entry point for client users. A session bean will usually manage, and provide indirect access to several entity beans. Using this architecture, network traffic can be substantially reduced. There are Stateful and Stateless beans (see below)
<i>Message Driven Beans</i>	Anonymous beans that cannot be referenced by a given client, but rather respond to JMS asynchronous messages. Like Session Beans, they provide a way of encapsulating business logic on the server side

Entity Beans

Entity beans are used to represent underlying objects. The most common application for entity beans is their representation of data in a relational database. A simple entity bean can be defined to represent a database table where each instance of the bean represents a specific row. More complex entity beans can represent views of joined tables in a database. One instance represents a specific customer and all of that customer's orders and order items.

The code generated is different depending on the type of Entity Bean (Container Managed Persistence or Bean Managed Persistence).

Stateful and Stateless Session Beans

A session bean is an EJB in which each instance of a session bean is created through its home interface and is private to the client connection. The session bean instance cannot be easily shared with other clients, this allows the session bean to maintain the client's state. The relationship between the client and the session bean instance is one-to-one.

Stateful session beans maintain conversational state when used by a client. A conversational state is not written to a database, it is a state kept in memory while a client uses a session.

Stateless session beans do not maintain any conversational state. Each method is independent, and uses only data passed in its parameters.

Message Driven Beans

They are stateless, server side components with transactional behavior that process asynchronous messages delivered via the Java Message Service (JMS). Applications use

asynchronous messaging to communicate by exchanging messages that leave senders independent from receivers.

EJB Properties

You can open the EJB page in the component property sheet to display the following properties:

Property	Description
Remote home interface	Defines methods and operations used in a remote client view. Extends the javax.ejb.EJBHome interface
Remote interface	Provides the remote client view. Extends the javax.ejb.EJBObject interface
Local home interface	Defines methods and operations used locally in a local client view. Extends the javax.ejb.EJBLocal-Home interface
Local interface	Allows beans to be tightly coupled with their clients and to be directly accessed. Extends the javax.ejb.EJBLocalObject interface
Bean class	Class implementing the bean business methods
Primary key class	Class providing a pointer into the database. It is linked to the Bean class. Only applicable to entity beans

Note: You can open the EJB page by right clicking the EJB component symbol in the diagram, and selecting EJB from the contextual menu.

For more information on interface methods and implementation methods, see *Understanding operation synchronization* on page 378.

Previewing the Component Code

You can preview the code of an EJB by clicking the Preview tab in the component property sheet. The Preview page contains tabbed pages that correspond to each interface and class of the EJB. You can see the relation between an EJB and its classes and interfaces from the Preview page without generating any file.

In the class and interface property sheets, the Preview page is a keyboard shortcut to show what will be generated.

In the model or package property sheet, the Preview page describes the EJB deployment descriptor file with the name of the generated EJB and its methods. It allows you to view what will be generated.

You can use the following tools and keyboard shortcuts from the Preview toolbar:

Tool	Description	Keyboard shortcut
	Open Editor Contextual menu	Shift + F11
	Refresh	F5
	Show Generation Options	ctrl + W
	Select Generation Targets	ctrl + F6

Showing Generation Options

If you click the Show Generation Options tool, the Generation Options dialog box is displayed. You can change generation options from this dialog box and see the impact on the code.

Select Generation Targets

This tool is available when at least one extended model definition flagged for generation is linked to the model, and when it contains entries in the Generated Files category for the current type of object. When available, it displays the list of targets for the current object. If you add a generation target, the corresponding tab is added to the Preview page. If you deselect a generation target, the corresponding tab disappears from the Preview page.

For more information on setting an extended model definition for generation, see "Extended Model Definitions" in the Resource Files and the Public Metamodel chapter of the *Customizing and Extending PowerDesigner* manual.

Script Bookmarks

In the Preview page, you can add and remove bookmarks at specific points in the code and then navigate forwards or backwards from bookmark to bookmark:

Keyboard shortcut	Description
ctrl + F2	Adds a new bookmark. A blue bookmark box is displayed. If you repeat this action from the same position, the bookmark is deleted and the blue marker disappears
F2	Jumps to bookmark
shift + F2	Jumps to previous bookmark

Note that bookmarks are not printable and are lost if you use the Refresh, or Show Generation Options tools.

Creating an EJB with the Wizard

You can create an EJB component with the *wizard* that will guide you through the creation of the component. It is only available if the language is Java.

The wizard is invoked from a *class diagram*. You can either create an EJB without selecting any class, or select a class first and start the wizard from the contextual menu of the class.

You can also create several EJBs of the same type by selecting several classes at the same time. The wizard will automatically create one EJB per class. The classes you have selected in the class diagram become the Bean classes. They are renamed to fit the naming conventions standard, and they are linked to their component.

If you have selected classes or interfaces before starting the wizard, they are automatically linked to the new EJB component.

When an interface or a class is already stereotyped, like <<EJBEntity>> for example, it is primarily used to be the interface or the class of the EJB.

For more information on stereotyped EJB interface or class, see section *Defining interfaces and classes for EJBs* on page 373.

The EJB creation wizard lets you define the following parameters:

Property	Description
Name	Name of the EJB component
Code	Code of the EJB component
Component type	Entity Bean CMP, Entity Bean BMP, Message Driven Bean, Session Bean Stateful, or Session Bean Stateless For more information on the different types of EJB, see section <i>Using EJB types</i> on page 367
Bean class	Class implementing the bean business methods
Remote interface	Extends the javax.ejb.EJBObject interface and provides the remote client view
Remote home interface	Defines methods and operations used in a remote client view. It extends the javax.ejb.EJBHome interface
Local interface	Extends the javax.ejb.EJBLocalObject interface, and allows beans to be tightly coupled with their clients and to be directly accessed
Local home interface	Defines methods and operations used locally in a local client view. It extends the javax.ejb.EJBLocal-Home interface
Primary key class	Class providing a pointer into the database. It is only applicable to entity beans

Property	Description
Transaction	Defines what transaction support is used for the component. The transaction is important for distribution across a network on a server. The transaction support value is displayed in the deployment descriptor. This information is given by the deployment descriptor to the server when generating the component
Create symbol	Creates a component symbol in the diagram specified beside the Create symbol In check box. If a component diagram already exists, you can select one from the list. You can also display the diagram properties by selecting the Properties tool
Create Class Diagram for component classifiers	Creates a class diagram with a symbol for each class and interface. If you have selected classes and interfaces before starting the wizard, they are used to create the component. This option allows you to display these classes and interfaces in a diagram

The Transaction support groupbox contains the following values, as per the Enterprise JavaBeans 2.0 specification from Sun Microsystems, Inc.

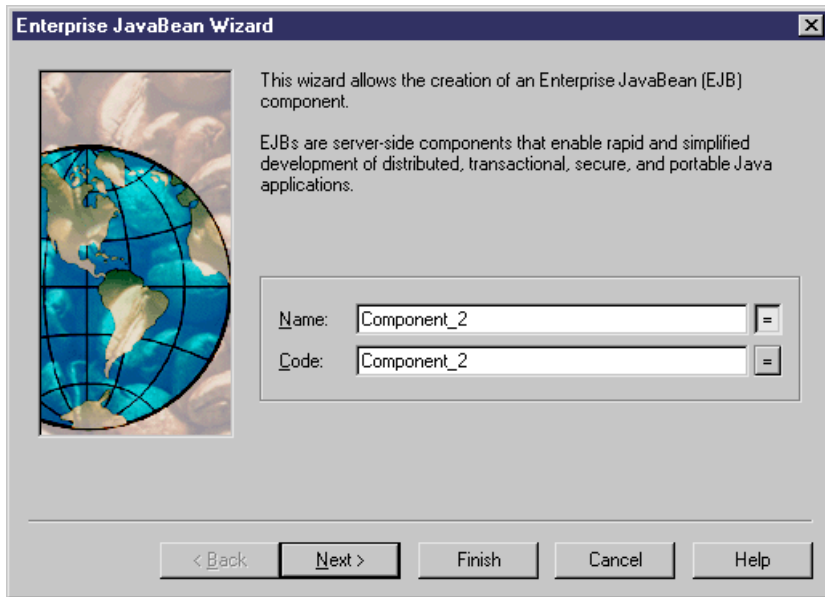

Transaction value	Description
Not Supported	The component does not support transaction, it does not need any transaction and if there is one, it ignores it
Supports	The component is awaiting a transaction, it uses it
Required	If there is no transaction, one is created
Requires New	The component needs a new transaction at creation, the server must provide it with a new transaction
Mandatory	If there is no transaction, an exception is thrown
Never	There is no need for a transaction

The EJB deployment descriptor supports transaction type for each method: you can specify a transaction type for each method of EJB remote and local interface.

You can define the transaction type for each method using an extended attribute from the Profile/Operation/Extended Attributes/EJB folder of the Java object language. If the transaction type of the operation is not specified (it is empty), the default transaction type defined in the component is used instead.

1. Select **Tools > Create Enterprise JavaBean** from a class diagram.

The Enterprise JavaBean Wizard dialog box is displayed.

Note: If you have selected classes before starting the wizard, some of the following steps are omitted because the different names are created by default according to the names of the selected classes.

2. Type a name and code for the component and click Next.
3. Select the component type and click Next.
4. Select the Bean class name and click Next.
5. Select the remote interface and the remote home interface names and click Next.
6. Select the local interface and the local home interface names and click Next.
7. Select the primary key class name and click Next.
8. Select the transaction support and click Next.
9. At the end of the wizard, you have to define the creation of symbols and diagrams.

When you have finished using the wizard, the following actions are executed:

- An EJB component is created
- Classes and interfaces are associated with the component, and any missing classes or interfaces associated with the component are added
- Any diagrams associated with the component are created or updated
- Depending on the EJB type, the EJB primary key class, its interfaces and dependencies are automatically created and visible in the Browser. In addition to this, all dependencies between remote interfaces, local interfaces and the Bean class of the component are created

- The EJB created is named after the original class if you have selected a class before starting the wizard. Classes and interfaces are also prefixed after the original class name to preserve coherence

Defining Interfaces and Classes for EJBs

An EJB comprises a number of specific interfaces and implementation classes. Interfaces of an EJB are always exposed, you define a public interface and expose it. You can attach an interface or class to only one EJB at a time.

EJB component interfaces are shown as circles linked to the EJB component side by an horizontal or a vertical line:

Interfaces provide a remote, or a local view as shown in the table below:

View	Interface
Remote view	Remote home interface Remote interface
Local view	Local home interface Local interface

The symbol of an interface can be moved, and the link from the EJB component to the interface can be extended. When an interface realizes an EJB component, the interface is necessarily visible.

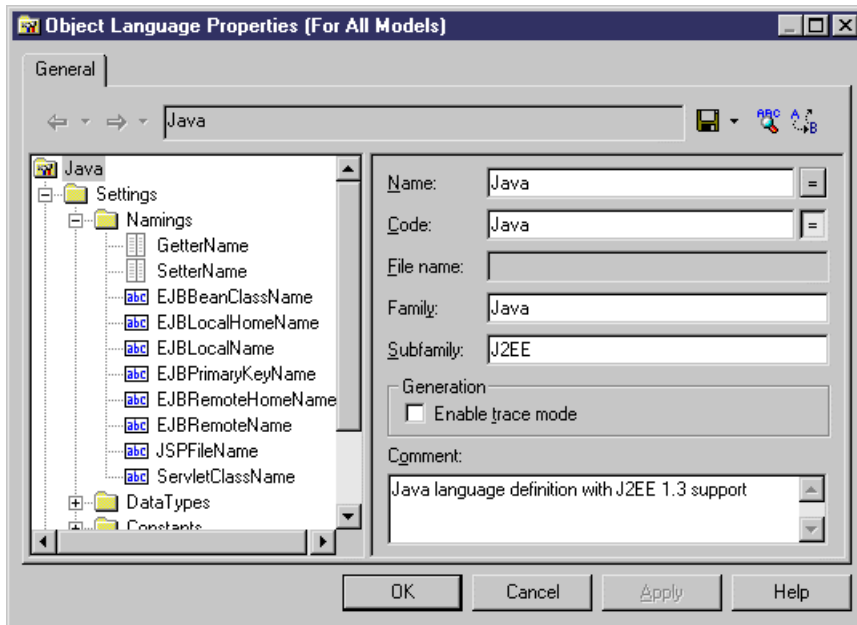

Note: You can double-click the circle, symbol of an interface to display the interface property sheet.

Classes have no symbol in the component diagram, unlike interfaces. However, the relationship between the class and the EJB component is visible from the Classes page of the EJB component property sheet, and from the Components tabbed page in the Dependencies page of the class property sheet.

The following table displays the stereotypes used to automatically identify EJB interfaces and classes:

Stereotype	Describes
<<EJBRemoteHome>>	The remote home interface
<<EJBRemote>>	The remote interface
<<EJBLocalHome>>	The local home interface

Stereotype	Describes
<<EJBLocal>>	The local interface
<<EJBEntity>>	The bean class of an entity bean
<<EJBSession>>	The bean class of a session bean
<<EJBMessageDriven>>	The bean class of a message driven bean
<<EJBPrimaryKey>>	The primary key class of an entity bean

Template names are instantiated with respect to the corresponding component and assigned to the newly created objects. If an unattached interface or class, matching a given name and classifier type already exists in the model, it is automatically attached to the EJB.

Naming Conventions

A *naming convention* is a common model option that you can define in the Model Options dialog box. It is useful to set rules in order to enforce predefined name formats for all the objects within a model. You can specify naming convention for related interfaces and classes in your object language in the **Settings > Namings category** category, available from **Language > Edit Current Object Language**.

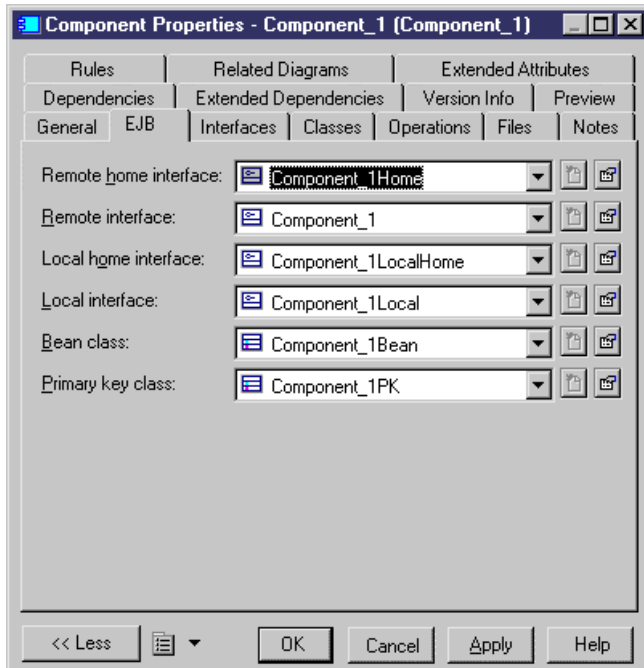

For more information on naming conventions, see "Naming Conventions" section in the Models chapter of the *Core Features Guide*.

Defining an Interface or a Class for an EJB

To define an interface or a class for an EJB:

1. Right-click the EJB component in the diagram and select EJB from the contextual menu.

The component property sheet opens to the EJB page. Interfaces and classes are created and attached to the EJB.

You can use the Create tool beside the interface or the class name to recreate an interface or a class if it is set to <None>.

2. Click the Properties button beside the interface or the class name box that you want to define.

The interface or the class property sheet is displayed.

3. Select properties as required.

The interfaces and classes definitions are added to the current EJB component definition.

Defining Operations for EJBs

You can create the following types of operations for an EJB from the property sheet of the Bean class or EJB interfaces:

- EJB Business Method (local)

- EJB Business Method (remote)
- EJB Create Method (local)
- EJB Create Method (remote)
- EJB Finder Method (local)
- EJB Finder Method (remote)
- EJB Select Method

Note: You cannot create an operation from the Operations page of the component property sheet as this page is only used to view the operations of the EJB component. You view operations of an EJB from the Operations page in the component property sheet

Stereotypes

The following standard stereotypes, as defined for EJBs, are assigned to these operations:

- <<EJBCreateMethod>>
- <<EJBFinderMethod>>
- <<EJBSelectMethod>>

CMP Entity Beans

You can create the following operations for CMP Entity Beans only:

- EJB Create(...) Method (local)
- EJB Create(...) Method (remote)

When you create an EJB Create(...) Method (local), the method is created in the local home interface with all the persistent attributes as parameters. When you create an EJB Create(...) Method (remote), the method is created in the remote home interface with all the persistent attributes as parameters.

Moreover, all linked methods `ejbCreate(...)` and `ejbPostCreate(...)` are created automatically in the Bean class with all the persistent attributes as parameters. Parameters are synchronized whenever a change is applied.

Note: If you need to modify the methods of an interface, you can do so from the Operations page of the interface property sheet.

Adding an Operation to the Bean Class

After creation of the Bean class, you may need to create a method that is missing at this stage of the process, such as an internal method.

1. Double-click the Bean class to display its property sheet.
2. Click the Operations tab, then click a blank line in the list.

An arrow is displayed at the beginning of the line.

3. Double-click the arrow at the beginning of the line.

A confirmation box asks you to commit the object creation.

4. Click Yes.

The operation property sheet is displayed.

5. Type a name and code for your operation.

6. Click the Implementation tab to display the Implementation page.

The Implementation page opens to the Body tabbed page.

7. Add the method code in this page.

8. Click OK.

You return to the class property sheet.

9. Click the Preview tab to display the Preview page.

You can now validate the to-be-generated Java code for the Bean class.

10. Click OK.

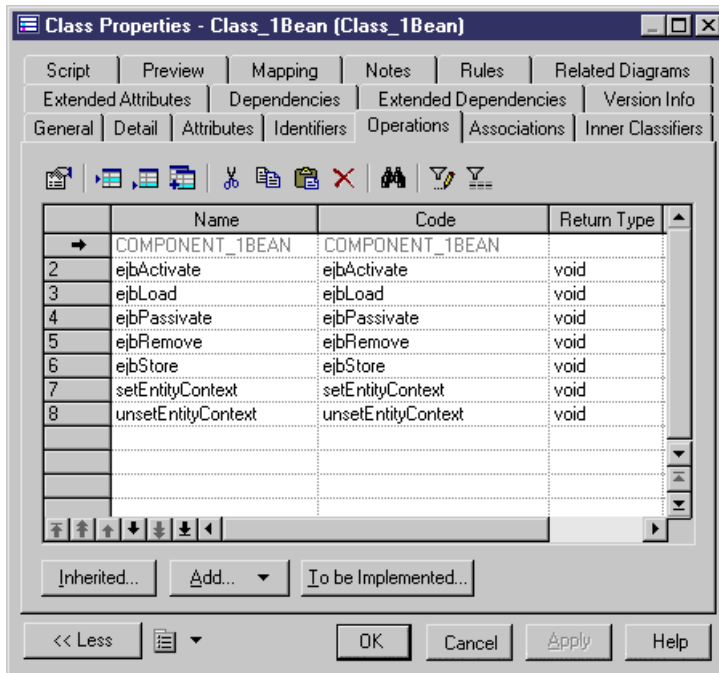

Adding an Operation to an EJB Interface

You can add an operation to an EJB interface from the interface property sheet or from the Bean class property sheet using the Add button in the Operations page.

When you add an operation to an interface, an implementation operation is automatically created in the Bean class because the interface operation has a linked method. This ensures operation synchronization.

For more information on synchronization, see *Understanding operation synchronization* on page 378

1. Double-click the Bean class to display the class property sheet.
2. Click the Operations tab to display the Operations page.
3. Click the Add button at the bottom of the page.
4. Select the required EJB operation from the list.

5. Click Apply.

The requested operation is created at the end of the list of operations in the Bean class property sheet, and you can also verify that the new operation is displayed in the interface operation list.

6. Click OK.

Understanding Operation Synchronization

Synchronization maintains the coherence of the whole model whenever a change is applied on operations, attributes, and exceptions. Synchronization occurs progressively as the model is modified.

Operation Synchronization

Synchronization occurs from interface to Bean class. Interface operations have *linked methods* in the Bean class with name/code, return type and parameters synchronized with the interface operation. When you add an operation to an interface, you can verify that the corresponding linked method is created in the Bean class (it is grayed in the list). Whereas no operation is created in an interface if you add an operation to a Bean class.

For example, double-click the Bean class of a component, click the Operations tab, click the Add button at the bottom of the Operations page, and select EJB Create method (local): PowerDesigner adds this operation to the interface and automatically creates the ejbCreate and ejbPostCreate operations in the Bean class.

Exception Synchronization

Exceptions are synchronized from the Bean class to interfaces. The exception list of the home interface create method is a superset of the union of the exception lists of the matching `ejbCreate` and `ejbPostCreate` implementation operations in the bean class.

The interface exception attributes are thus updated whenever the exception list of the bean class implementation method is modified.

Understanding EJB Support in an OOM

PowerDesigner simplifies the development process by transparently handling EJB concepts and enforcing the EJB programming contract through the following levels of support:

- Automatic initialization: occurs whenever a class or interface is attached to an EJB
- Synchronization: occurs between interfaces and classes already attached to a component
For more information on the linked method, see *Understanding EJB synchronization* on page 380.
- Model checks: the Check Model feature validates a given model and complements synchronization by offering auto-fixes. You can check your model at any time using the Check Model feature from the Tools menu.
For more information on the Check Model feature, see *Chapter 10, Checking an OOM* on page 313.
- Template based code generation: supports the programming contract defined in the specification and allows you to customize generated code. EJB specific templates can be found in the Java object language in the Profile/Component/Templates category, available from **Language > Edit Current Object Language**.

For more information, see sections Responsibilities of the Bean Provider, in all chapters related to Bean component contract in the Enterprise JavaBeans 2.0 specification from Sun Microsystems, Inc.

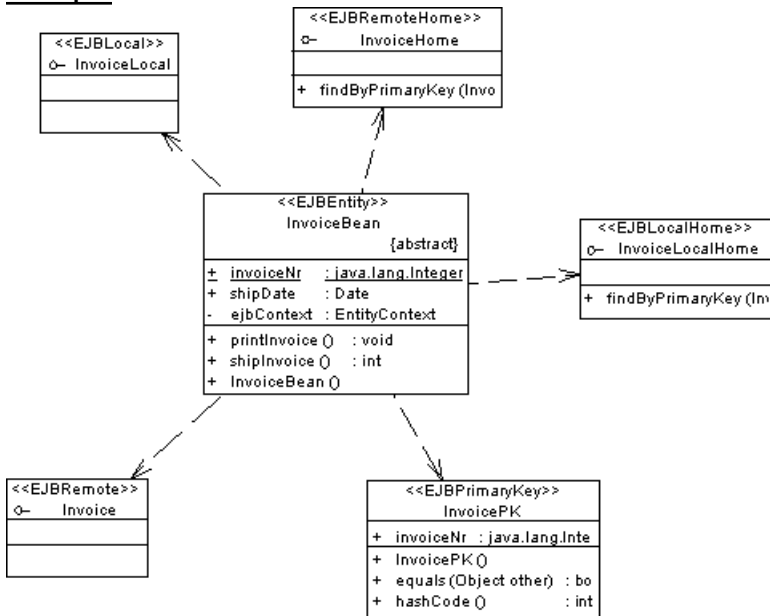

At a higher level, PowerDesigner supports different approaches to assist you in the component development process including:

- Forward engineering: from an OOM to a PDM. It provides the ability to create and reverse EJBs in a OOM, generate the corresponding PDM, O/R Mapping and generate code
- Reverse engineering: from a PDM (database) to an OOM. It provides the ability to create and reverse tables in a PDM, generate corresponding classes, create EJB from given classes and generate code

Understanding EJB Initialization

When creating an EJB, the role of the initialization process is to initialize classes and interfaces with respect to the EJB programming contract. It instantiates the classes and interfaces together with their methods.

Example

Understanding EJB Synchronization

Synchronization maintains the coherence of the whole model whenever a change is applied.

It occurs progressively as the following model items are modified:

- Operations. Synchronization occurs from interface to Bean class with linked methods. See *Understanding operation synchronization* on page 378.
- Exceptions. Synchronization occurs from Bean class to interface. See *Understanding operation synchronization* on page 378.
- Primary identifier Attribute. Synchronization occurs from Bean class to Primary key class, when attribute is primary identifier in Bean class it is automatically migrated to primary key class

Understanding EJB Code Generation

The code generation mechanism is only described for Entity beans CMP in this section since the code generated is handled and stored in the Container. With Entity beans BMP, session

beans and message-driven beans, the code generated is highly dependent on the bean developer's input, it would thus not be possible to introduce each possible configuration here.

The process of code generation is explained below in order for you to understand the mechanism:

The generation of EJB class and interface into code is performed like if they were Java classes, except that they are dependent on an EJB and thus contain more information to be processed during generation.

The code generation process performs the following tasks:

1. It creates the following inheritance links:
 - The local home interface inherits `javax.ejb.EJBLocalHome`
 - The local interface inherits `javax.ejb.EJBLocalObject`
 - The remote home interface inherits `javax.ejb.EJBHome`
 - The remote interface inherits `javax.ejb.EJBObject`

Here is an example from the Preview page of the remote interface:

```

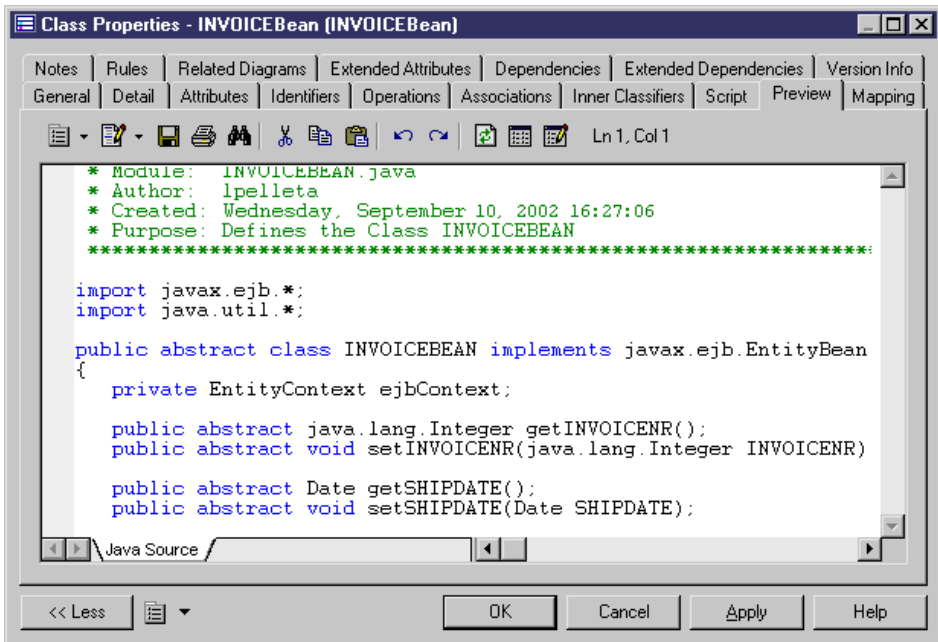

*****
* Module: INVOICE.java
* Author: lpelletta
* Modified: Wednesday, September 10, 2002 16:17:56
* Purpose: Defines the Interface INVOICE
*****/

import java.rmi.RemoteException;
import java.util.*;

public interface INVOICE extends javax.ejb.EJBObject
{
    public java.lang.Integer getINVOICENR() throws java.rmi.Remote
    public Date getSHIPDATE() throws java.rmi.RemoteException;
    public void setSHIPDATE(Date SHIPDATE) throws java.rmi.Remote
}
  
```

2. It creates the following realization links:
 - The Primary key class implements `java.io.Serializable`
 - The Bean class implements `javax.ejb.EntityBean`

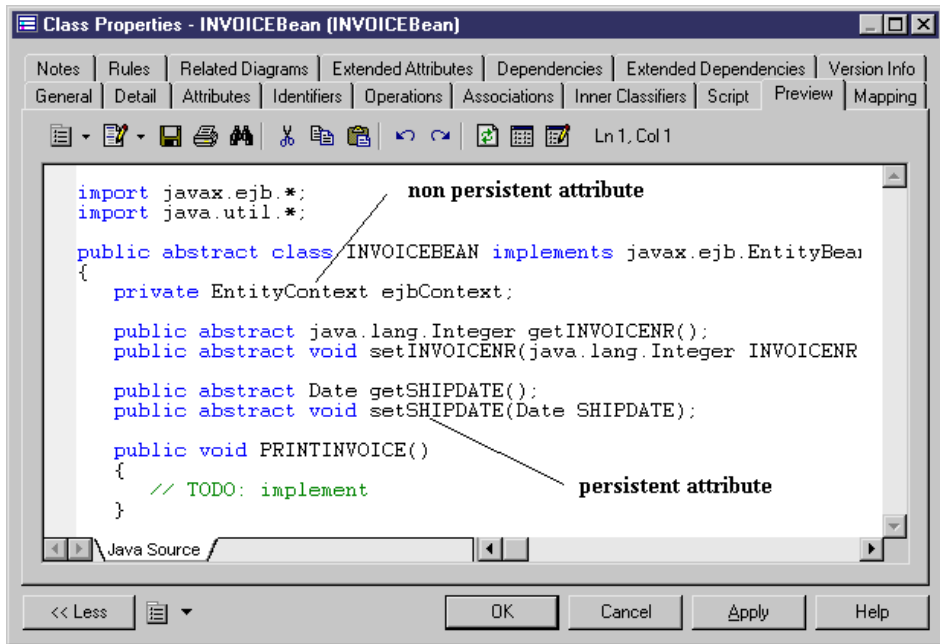

Here is an example from the Preview page of the Bean class:

3. It transforms attributes flagged as persistent into getter and setter methods (cmp-fields and cmr-fields are generated as getters and setters).

cmp-fields are attributes flagged as Persistent in the property sheet. cmr-fields are attributes that are migrated from associations.

Here is an example from the Preview page of the Bean class:

Previewing the EJB Deployment Descriptor

An EJB deployment descriptor describes the structure and properties of one or more EJBs in an XML file format. It is used for deploying the EJB in the application server. It declares the properties of EJBs, the relationships and the dependencies between EJBs. One deployment descriptor is automatically generated per package or model, it describes all EJBs defined in the package.

The role of the deployment descriptor, as part of the whole process is shown in the following figure:

The EJB deployment descriptor and the compiled Java classes of the EJBs should be packaged in a JAR file.

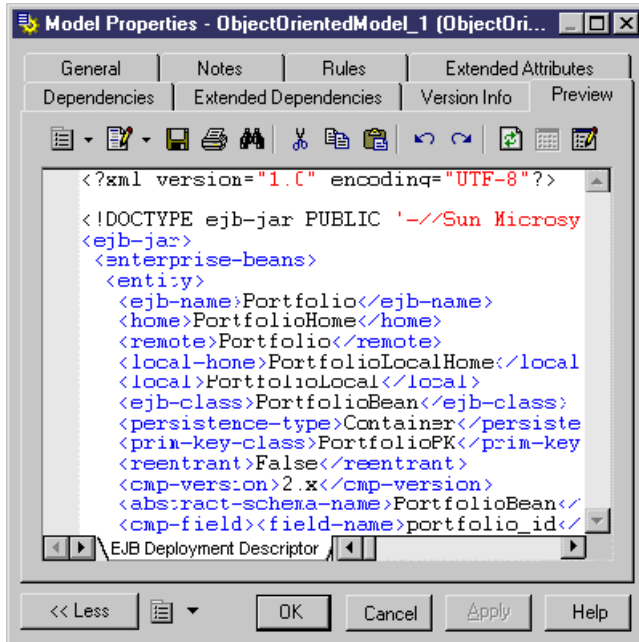

The EJB deployment tool of the application server imports the Java classes from the JAR file and configures the EJBs in the application server based on the description of EJBs contained in the EJB deployment descriptor.

You can see the deployment descriptor from the Preview page of the package or model property sheet.

You can customize the EJB deployment descriptor by modifying the templates in the Java object language.

For more information on customizing the object language, see *Chapter 1, Resource Files and the Public Metamodel* in *Customizing and Extending PowerDesigner*.

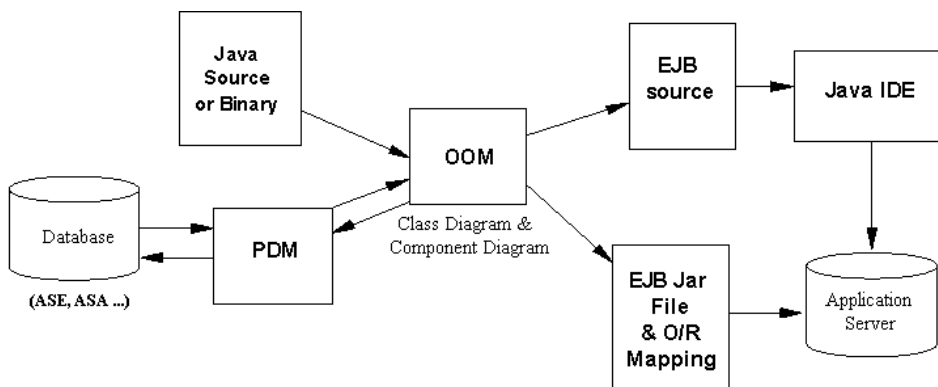

1. Right-click the model in the Browser and select **Properties** to open the model property sheet.
2. Click the **Preview** tab.

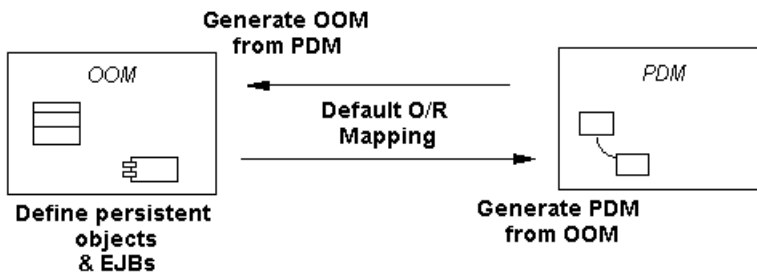

Generating EJBs

The EJB generation process allows you to generate EJB source code that is compliant with J2EE 1.3 (EJB 2.0). The code generator (Java, EJB, XML, etc...) is based on templates and macros. You can customize the generated code by editing the Java object language from **Tools > Resources > Object Languages**.

The following picture illustrates the overall EJB development process.

The following picture focuses on the PowerDesigner part, and highlights the role of O/R Mapping generation. The O/R mapping can be created when generating a PDM from an OOM or generating an OOM from a PDM.

For more information on object mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

What Kind of Generation to Use?

You may face two situations when generating EJB source code:

- You have no database
- You already have a database

You want to generate EJB source code when creating a database. If there is no database, the development process is the following:

- Define persistent objects in the class diagram, and define EJBs in the component diagram
- Generate the Physical Data Model, with creation of an O/R Mapping during generation
- Create the database
- Generate EJB source code and deployment descriptor for deployment in the application server

You want to generate EJB source code for an existing database. If the database already exists, you may want to wrap the existing database into EJBs and use EJBs to access the database. The development process is the following:

- Reverse engineer the PDM into an OOM, and retrieve the O/R mapping generated during reverse
- Define EJBs in the OOM based on persistent classes
- Generate the EJB source code and deployment descriptor for deployment in the application server

You can also use generation of EJB source code when managing persistence of EJBs with an existing database. For example, it may be necessary to manage the persistence of an already defined EJB with an existing database. Since you cannot change the definition of EJB nor the database schema, you need a manual object to relational mapping in this case.

For more information on object mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

Understanding EJB Source and Persistence

You generate persistence management methods based on the object language. Depending if the EJB is of a CMP or BMP type, the deployment descriptor file is displayed different:

- A CMP involves the application server. It includes the EJB and the O/R mapping descriptor (.XML). The server retrieves both EJB and O/R mapping descriptor to generate the code

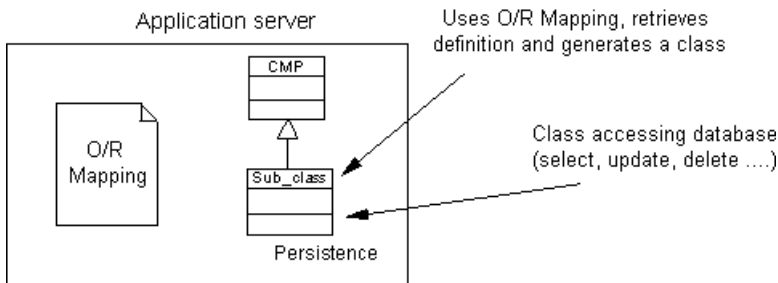

If the application server does not support an O/R Mapping descriptor, the mapping must be done manually. If the O/R mapping descriptor of your application server is not supported yet, you can create your own by creating a new extended model definition.

For more information on creating an extended model definition, see "Extended Model Definitions" in the Resource Files and the Public Metamodel chapter of the *Customizing and Extending PowerDesigner* manual.

- A BMP involves a manual process. It includes the EJB source, without any O/R mapping descriptor (O/R mapping is not necessary). The BMP developer should implement the persistence management him/herself by implementing the `ejbStore()`, and `ejbLoad()` methods, the application server only supports its functions. An implementation class

inherits from the BMP Bean class, handles persistence data and communicates with the database

- You can also define an EJB as CMP, then generate it as BMP when generating the code. The code generator generates an implementation class (sub-class) for the Bean class that contains its methods, and uses an O/R mapping and a persistent template to implement the persistence

For more information on defining O/R mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

You can use different methods to generate an EJB CMP into an EJB BMP. You can either copy the Java object language delivered in PowerDesigner as a reference to a new object language, and describe how to generate implementation classes of the EJB CMP in your own object language, or you can create an extended model definition that includes these implementation classes.

You could also write a VB script to convert the EJB CMP into an EJB BMP. To do this, you must generate the EJB as CMP, then launch the VB script that will go through all objects of the model and generate an implementation class for each identified class.

Generating EJB Source Code and the Deployment Descriptor

When generating an EJB, classes and interfaces of the EJB are directly selected. The generation retrieves the classes used by the component, as well as the interfaces associated with the classes.

1. Select **Language > Generate Java Code** to open the Generation dialog.
2. Enter the directory in which you want to generate the Java files.
3. [optional] Click the **Selection** tab and select the objects that you want to generate. By default, all objects are generated.
4. [optional] Click the **Options** tab and select any appropriate generation options (see *Selecting Java Generation Options* on page 416).
5. [optional] Click the **Tasks** tab and select any appropriate task to perform during generation (see *Selecting Java Generation Tasks* on page 418).
6. Click **OK** to begin generation.

A progress box is displayed, followed by a Result list. You can use the Edit button in the Result list to edit the generated files individually.

7. Click **Close**.

The `ejb-jar.xml` deployment descriptor is created in the META-INF directory and all files are generated in the generation directory.

Generating JARs

In order to package the EJB, the bean classes, interfaces and the deployment descriptor are placed into a .JAR file. This process is common to all EJB components.

You can generate .JAR files from the Tasks page of the Generation dialog box (**Language > Generate Java Code**).

For example, one of the task allows you to compile .JAVA files using a compiler, to create a .JAR file including the compiled Java classes, and to complete the .JAR file with the deployment descriptor and icons.

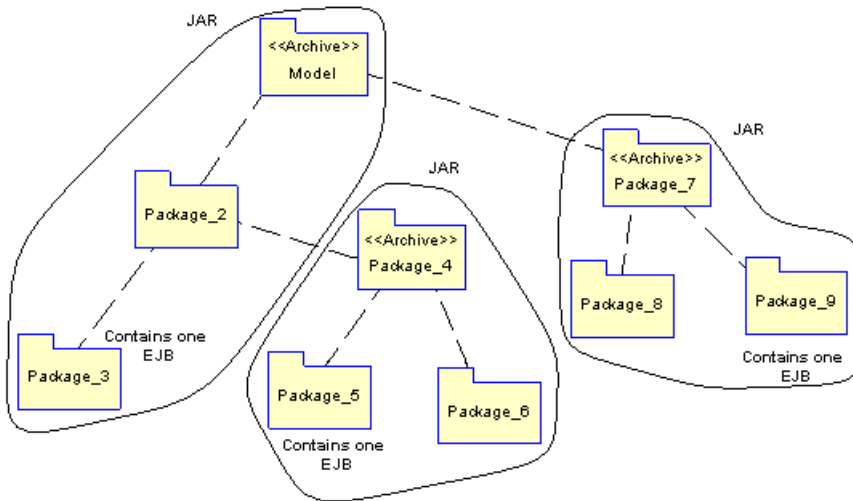

Warning! You must set the values of the commands used during generation from the Variables section of the General Options dialog box in order to enable them. For example, you can set the `javac.exe` and `jar.exe` executables at this location.

For more information on how to set these variables, see "Defining environment variables" section in the Models chapter of the *General Core Guide*.

There is no constraint over the generation of one JAR per package. Only packages with the `<<archive>>` stereotype will generate a JAR when they (or one of their descendant package not stereotyped `<<archive>>`) contain one EJB.

The newly created archive contains the package and all of its non-stereotyped descendants. The root package (that is the model) is always considered as being stereotyped <<archive>>.

For example, if a model contains several EJB components in different sub-packages but that none of these packages is stereotyped <<archive>>, a single JAR is created encompassing all packages.

Reverse Engineering EJB Components

PowerDesigner can reverse engineer EJB components located in .JAR files.

1. Select **Language > Reverse Engineer Java** to open the Reverse Engineer Java dialog.
2. On the **Selection** tab, select Archives from the **Reverse** list.
3. Click the **Add** button, navigate to and select the objects that you want to reverse, and then click **Open** to add them to the list.
4. Click the **Options** tab and select the **Reverse Engineer Deployment Descriptor** check box.
5. Click **OK**.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see *Chapter 7, Comparing and Merging Models* in the *Core Features Guide*.

6. Click **OK**.

The Reverse page of the Output window displays the changes that occurred during reverse and the diagram window displays the updated model.

Enterprise Java Beans (EJBs) V3

The specification for EJB 3.0 attempts to simplify the complexity of the EJB 2.1 architecture by:

- decreasing the number of programming artefacts that developers need to provide
- minimizing the number of required callback methods
- reducing the complexity of the entity bean programming model and the O/R mapping model

The two most significant changes in the proposed EJB 3.0 specification are:

- *An annotation-based EJB programming model* - all kinds of enterprise beans are just plain old Java objects (POJOs) with appropriate annotations. A configuration-by-exception approach uses intuitive defaults to infer most common parameters. Annotations are used to define the bean's business interface, O/R mappings, resource references, and other information previously defined through deployment descriptors or interfaces. Deployment descriptors are not required; the home interface is gone, and it is no longer necessary to implement a business interface (the container can generate it for you). For example, you declare a stateless session bean by using the `@Stateless` annotation. For stateful beans, the `@Remove` annotation is marked on a particular method to indicate that the bean instance should be removed after a call to the marked method completes.
- *The new persistence model for entity beans* - The new entity beans are also just POJOs with a few annotations and are not persistent entities by birth. An entity instance becomes persistent once it is associated with an `EntityManager` and becomes part of a persistence context, which is loosely synonymous with a transaction context and implicitly coexists with a transaction's scope.

The entity relationships and O/R mapping is defined through annotations, using the open source Hibernate framework (see the "Generating Hibernate Persistent Objects and JSF Pages" chapter in *Integrating with Other Products* for information about PowerDesigner's support for Hibernate).

There are also several side effects to these proposals, such as a new client-programming model, use of business interfaces, and an entity bean life cycle.

Please note that the EJB 2.1 programming model (with deployment descriptors and home/remote interfaces) is still valid (and supported by PowerDesigner). The new simplified model, which is only available with Java 5.0, does not entirely replace the EJB 2.1 model.

Creating an EJB 3.0 with the Enterprise JavaBean Wizard

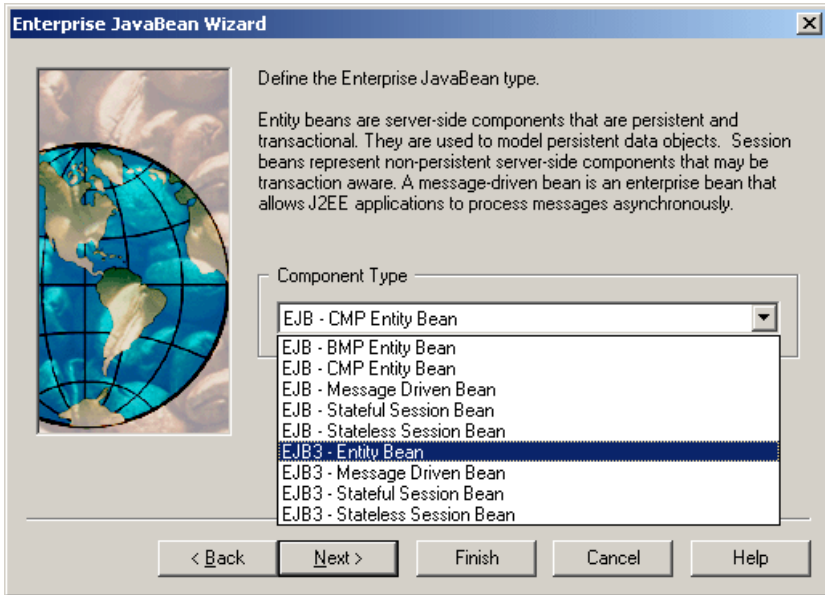

To create an EJB3, launch the Enterprise JavaBean Wizard from a class diagram. The following types of EJB3 beans are available:

- Entity Bean – generated with an `@Entity` annotation

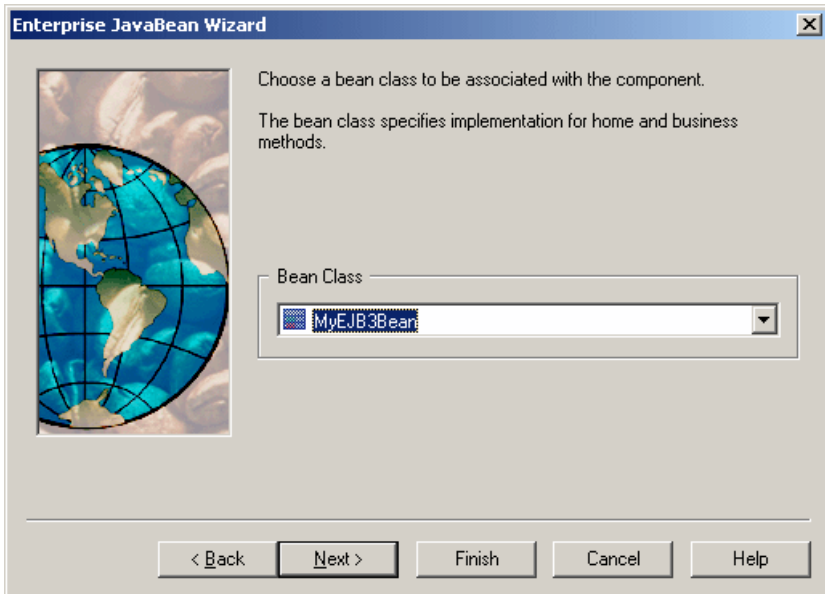

- Message Driven Bean – generated with a @MessageDriven annotation
 - Stateful Session Bean – generated with an @Stateful annotation
 - Stateless Session Bean – generated with an @Stateless annotation
1. If you have already created a class to serve as the BeanClass, then right click it and select Create Enterprise JavaBean from the contextual menu. Otherwise, to create an EJB 3.0 along with a new BeanClass, Select **Tools > Create Enterprise JavaBean**. In either case, the Enterprise JavaBean Wizard opens:

2. Specify a name for the EJB, and then click Next to go to the next screen:

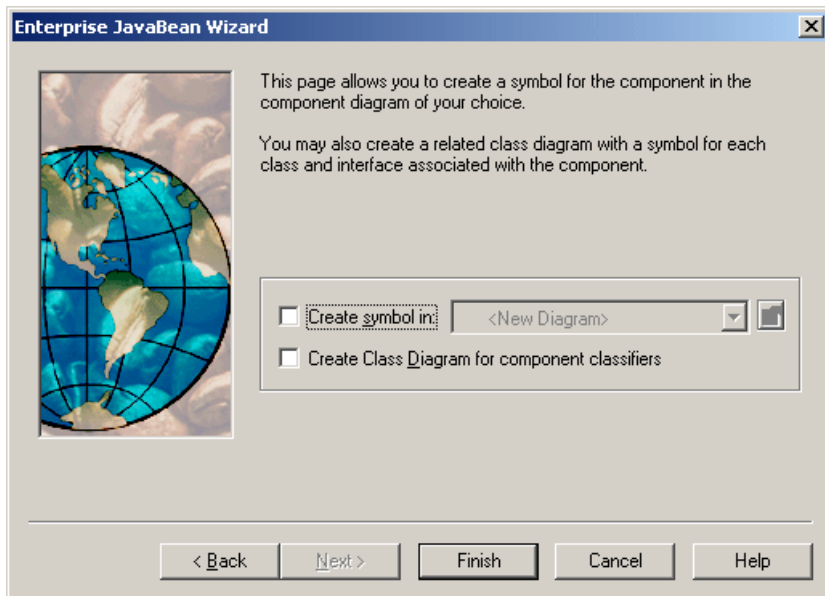

3. Choose a type of EJB3, and then click Next to go to the next screen:

4. Choose a Bean Class. If you have not selected a class before launching the wizard, a default class with the same name as the component will be suggested. Otherwise the original class will be selected. Then click Next to go to the next screen:

5. Choose the desired level of transaction support, and then click Next to go to the next screen:

6. Select the appropriate checkboxes if you want to create diagrams for the component and/or the component classifiers, and then click Finish to instruct PowerDesigner to create them.

EJB 3.0 BeanClass Properties

A BeanClass is the primary class contained within an EJB 3.0 component. EJB 3.0 BeanClass property sheets contain all the standard class tabs along with the EJB3 tab, the properties of which are listed below:

Property	Description
Transaction Management	<p>Specifies the method of transaction management for a Session Bean or a Message Driven Bean. You can choose between:</p> <ul style="list-style-type: none"> • Bean • Container <p>Generated as a <code>@TransactionManagement</code> annotation.</p>
Transaction Attribute Type	<p>Transaction Attribute Type for the Bean Class</p> <p>Specifies the transaction attribute type for a Session Bean or a Message Driven Bean. You can choose between:</p> <ul style="list-style-type: none"> • Not Supported • Supports • Required • Requires New • Mandatory • Never <p>Generated as a <code>@TransactionAttribute</code> annotation.</p>
Exclude Default Interceptors	<p>Specifies that the invocation of default interceptor methods is excluded.</p> <p>Generated as a <code>@ExcludeDefaultInterceptors</code> annotation.</p>
Exclude Superclass Listeners	<p>Specifies that the invocation of superclass listener methods is excluded.</p> <p>Generated as a <code>@ExcludeSuperclassListeners</code> annotation.</p>
Mapped Name	<p>Specifies a product specific name.</p> <p>Generated as a <code>@MappedName</code> annotation.</p>
Run-As	<p>Specifies the bean's run-as property (security role).</p> <p>Generated as a <code>@RunAs</code> annotation.</p>
Declare Roles	<p>Specifies references to security roles.</p> <p>Generated as a <code>@DeclareRoles</code> annotation.</p>
Roles Allowed	<p>Specifies the roles allowed for all bean methods.</p> <p>Generated as a <code>@RolesAllowed</code> annotation.</p>

Property	Description
Permit All	Specifies that all roles are allowed for all bean business methods. Generated as a @PermitAll annotation.

EJB 3.0 Component Properties

EJB 3.0 component property sheets contain all the standard component tabs along with the EJB tab, the properties of which are listed below:

Property	Description
Bean class	Specifies the associated bean class.
Remote home interface	[session beans only] Specifies an optional remote home interface (for earlier EJB clients).
Local home interface	[session beans only] Specifies the local home interface (for earlier EJB clients).

Adding Further Interfaces and Classes to the EJB

In addition to the bean class and remote and home interfaces defined on the EJB tab, you can link the following supplementary classes and interfaces to the EJB3:

- An optional collection of remote interfaces with <<EJBRemote>> stereotypes. Generated as a @Remote annotation.
- An optional collection of local interfaces with <<EJBLocal>> stereotypes. Generated as a @Local annotation.
- An optional collection of interceptor classes with <<EJBInterceptor>> stereotypes. Generated as an @Interceptors annotation.
- An optional collection of entity listener classes with <<EJBEntityListener>> stereotypes. Generated as an @EntityListeners annotation.

You add these interfaces and classes to the EJB3 component via the Interfaces and Classes tabs. For example, you can add an <<EJBInterceptor>> Interface to an EJB3:

1. Open the property sheet of the EJB3 and click the Interfaces tab.
2. Click the Create a New Object tool to create a new interface and open its property sheet.
3. On the General tab, select <<EJBInterceptor>> from the list of stereotypes.
4. Complete the remaining properties as required and then click OK to return to the EJB3 property sheet.

EJB 3.0 Operation Properties

EJB operation 3.0 property sheets contain all the standard operation tabs along with the EJB3 tab, the properties of which are listed below:

Property	Description
Initialize Method	Specifies an initialize method. Generated as a @Init annotation.
Remove Method	Specifies an remove method. Generated as a @Remove annotation.
Post-Construct	Specifies a post construct method. Generated as a @PostConstruct annotation.
Post-Activate	Specifies a post activate method. Generated as a @PostActivate annotation.
Pre-Passivate	Specifies a pre passivate method. Generated as a @PrePassivate annotation.
Pre-Destroy	Specifies a pre destroy method. Generated as a @PreDestroy annotation.
Interceptor Method	Specifies an interceptor method. Generated as a @AroundInvoke annotation.
Timeout Method	Specifies a timeout method. Generated as a @Timeout annotation.
Exclude Default Interceptors	Excludes invocation of default interceptor for the method. Generated as a @ExcludeDefaultInterceptors annotation.
Exclude Class Interceptors	Excludes invocation of class-level interceptors for the method. Generated as a @ExcludeClassInterceptors annotation.
Transaction Attribute Type	Specifies a Transaction Attribute Type for the method. Generated as a @TransactionAttribute annotation.
Permit All Roles	Specifies that all roles are permitted for the method. Generated as a @PermitAll annotation.
Deny All Roles	Specifies that method may not be invoked by any security role. Generated as a @DenyAll annotation.

Property	Description
Roles Allowed	Specifies the roles allowed for the method. Generated as a @RolesAllowed annotation.

Java Servlets

Servlets are programs that help in building applications that generate dynamic Web pages (HTML, XML). Servlets are a Java-equivalent of the CGI scripts and can be thought of as a server-side counterpart to the client-side Java applets.

Servlets are Java classes that implement a specific interface and produce HTML in response to GET/POST requests.

In an OOM, a servlet is represented as a component, it is linked to a servlet class that implements the required interface and provides the servlet implementation.

When you set the type of the component to Servlet, the appropriate servlet class is automatically created, or attached if it already exists. The servlet class is initialized so that operations are automatically added.

Servlet Page of the Component

When you set the type of the component to Servlet, the Servlet page is automatically displayed in the component property sheet.

The Servlet page in the component property sheet includes the following properties:

Property	Description
Servlet class	Class that implements the required interface. You can click the Properties tool beside this box to display the property sheet of the class, or click the Create tool to create a class
Servlet type	HttpServlet supports the http protocol, it is the most commonly used. GenericServlet extends the servlet generic class. User-defined implies some customization as it does not implement anything. The methods vary if you change the servlet type value

Defining Servlet Classes

Servlet classes are identified using the <<ServletClass>> stereotype.

The servlet class name is synchronized with the component name following the convention specified in the Value box of the Settings/Namings/ServletClassName entry in the Java object language.

Creating a Servlet with the Wizard

You can create a servlet with the *wizard* that will guide you through the creation of the component. The wizard is invoked from a *class diagram*. It is only available if the language is Java.

You can either create a servlet without selecting any class, or select a class beforehand and start the wizard from the contextual menu of the class.

You can also create several servlets of the same type by selecting several classes at the same time. The wizard will automatically create one servlet per class. The classes you have selected in the class diagram become servlet classes. They are renamed to fit the naming conventions standard, and they are linked to the new servlet component.

The wizard for creation of a servlet lets you define the following parameters:

Wizard page	Description
Name	Name of the servlet component
Code	Code of the servlet component
Servlet type	You can select the following types: HttpServlet that supports the http protocol (most commonly used), GenericServlet that extends the servlet generic class, or user-defined that implies some customization as it does not implement anything
Servlet class	Class that provides the Servlet implementation.
Create symbol	Creates a component symbol in the diagram specified beside the Create symbol In check box. If a component diagram already exists, you can select one from the list. You can also display the diagram properties by selecting the Properties tool
Create Class Diagram for component classifiers	Creates a class diagram with a symbol for each class. If you have selected classes before starting the wizard, they are used to create the component. This option allows you to display these classes in a diagram

1. Select **Tools > Create Servlet** from a class diagram.

The Java Servlet Wizard dialog box is displayed.

Note: If you have selected classes before starting the wizard, some of the following steps are omitted because the different names are created by default according to the names of the selected classes.

2. Select a name and code for the servlet component and click Next.
3. Select a servlet type and click Next.
4. Select the servlet class name and click Next.
5. At the end of the wizard, you have to define the creation of symbols and diagrams.

When you have finished using the wizard, the following actions are executed:

- A servlet component is created
- The servlet class is created and visible in the Browser. It is named after the original class if you have selected a class before starting the wizard
- If you have not selected a class beforehand, it is prefixed after the original default component name to preserve coherence
- Any diagrams associated with the component are created or updated

Understanding Servlet Initialization and Synchronization

When creating a servlet, the initialization process instantiates the servlet class together with its methods.

The role of the synchronization is to maintain the coherence of the whole model whenever a change is applied. It occurs progressively between classes already attached to a component. PowerDesigner successively performs several actions to complete synchronization as the model is modified.

The initialization and synchronization of the servlet class works in a similar way as with Message Driven bean classes:

- When the servlet class is attached to a servlet component, implementation methods for operations defined in the `javax.servlet.Servlet` interface are added by default. This interface is the base interface for all servlets, it may be included in the code depending on the servlet type selected. For `HttpServlet` and `GenericServlet`, the servlet class being directly derived from a class that implements it, it does not need to reimplement the interface. On the contrary, for user-defined servlets, this interface is implemented. You can see it from the Preview page of the servlet class.
- Implementation methods are removed when the class is detached if their body has not been altered
- The actual set of predefined methods vary depending on the servlet type

You can use the Check Model feature at any time to validate your model and complement the synchronization by selecting **Tools > Check Model**.

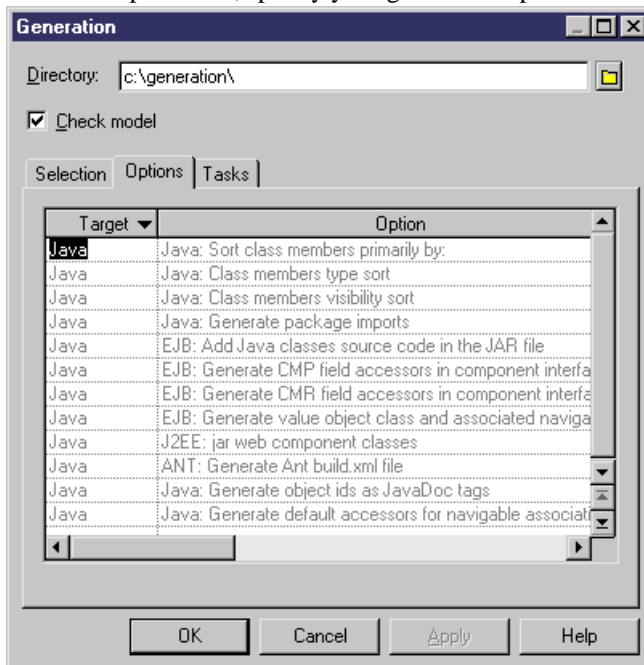

Generating Servlets

The generation process retrieves all classes used by the servlet components to generate the servlets.

1. Select **Language > Generate Java Code** to display the Generation dialog box.
2. Select or browse to a directory that will contain the generated files.
3. Click the Selection tab, then select the objects you need in the different tabbed pages.

4. Click Apply.
5. Click the Options tab, specify your generation options.

For more information on the generation options, see *Selecting Java Generation Options* on page 416.

6. Click Apply.
7. Click the Tasks tab, then select the commands you want to perform during generation.

For more information on the generation tasks, see *Selecting Java Generation Tasks* on page 418.

You must beforehand set your environment variables from **Tools > General Options > Variables** in order to activate them in this page.

For more information on how to set these variables, see "Defining environment variables" section in the Models chapter of the *Core Features Guide*.

8. Click OK.

A progress box is displayed, followed by a Result list. You can use the Edit button in the Result list to edit the generated files individually.

9. Click Close.

The web.XML file is created in the WEB-INF directory and all files are generated in the generation directory.

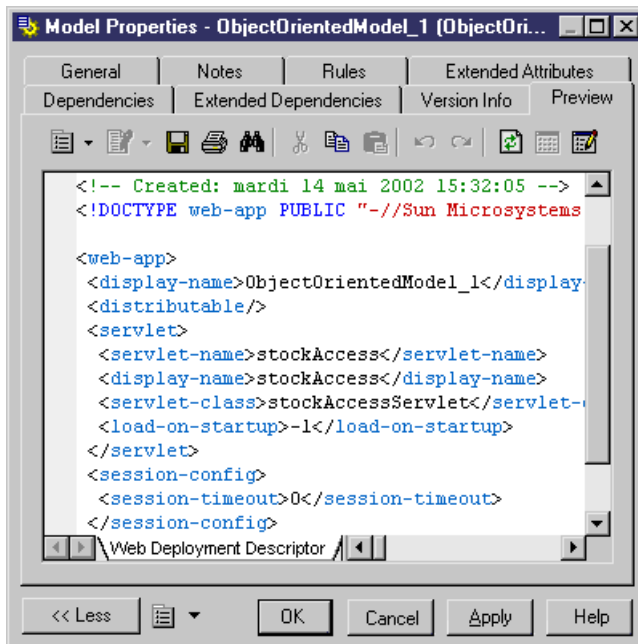

Generating Servlet Web Deployment Descriptor

The Web deployment descriptor is an XML file, called web.XML. It is generated in the WEB-INF directory and is independent from the application server.

For more information on generating the Web deployment descriptor, see *Generating servlets* on page 402.

The Web application deployment descriptor is generated per package. A WAR command available in the Tasks page of the Generation dialog box allows you to build a Web Archive that contains the Web deployment descriptor, in addition to all classes and interfaces referenced by servlet components. At the model level, an EAR command is also provided to group all WAR and JAR files generated for a given model inside a single enterprise archive. The EAR contains an additional deployment descriptor generated per model that is called application.XML.

The Web deployment descriptor contains several servlets to be deployed, it is available from the Preview page of the package, or the model property sheet.

Generating WARs

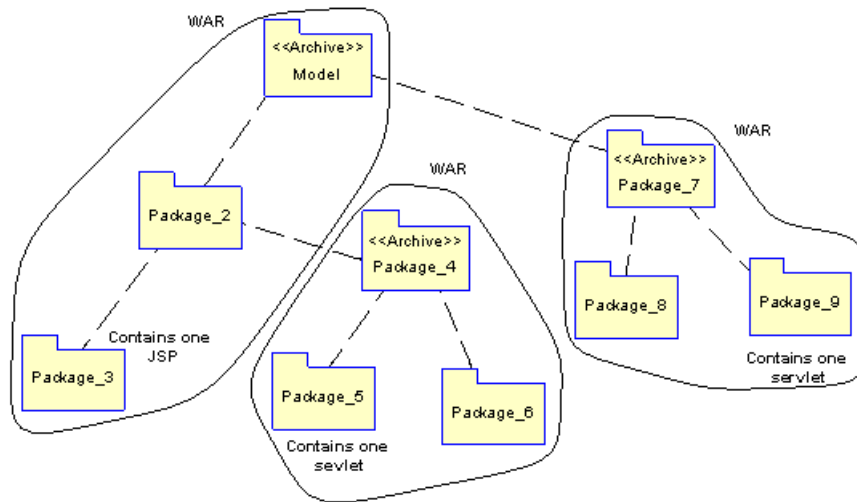

You can package servlets and JSPs into a .WAR file.

You can generate .WAR files from the Tasks page of the Generation dialog box (**Language > Generate Java Code**).

There is no constraint over the generation of one WAR per package. Only packages with the <<archive>> stereotype will generate a WAR when they (or one of their descendant package not stereotyped <<archive>>) contain one servlet, or one JSP.

The newly created archive contains the package and all of its non-stereotyped descendants. The root package (that is the model) is always considered as being stereotyped <<archive>>.

For example, if a model contains several Web components in different sub-packages but that none of these packages is stereotyped <<archive>>, a single WAR is created encompassing all packages.

For more information on generating WARs, see *Selecting Java Generation Tasks* on page 418.

Reverse Engineering Servlets

You can reverse engineer servlet code and deployment descriptor into an OOM. The reverse engineering feature reverses the Java class as a servlet class, it reverses the servlet as a component, and associates the servlet class with this component. The reverse engineering feature also reverses the deployment descriptor and all the files inside the WAR.

You start reverse engineering servlet from **Language > Reverse Engineer Java**.

Select one of the following Java formats from the Selection page, and select the Reverse Engineer Deployment Descriptor check box from the Options page:

- Java directories
- Class directories
- Archive (.JAR file)

For more information on the Java formats, see *Reverse Engineering Java Code* on page 421.

1. Select **Language > Reverse Engineer Java**.

The Reverse Java dialog box is displayed.

2. Select Archive from the Reverse list in the Selection page.

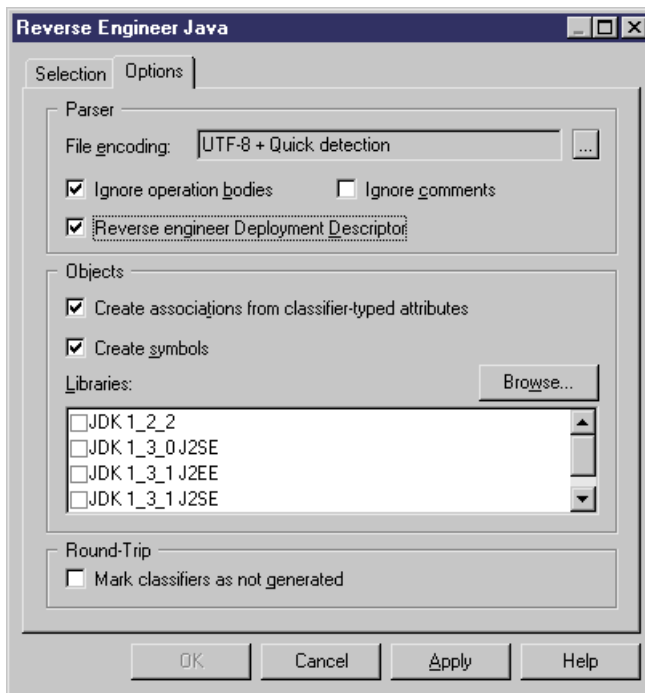

3. Click the Add button.

A standard Open dialog box is displayed.

4. Select the items you want to reverse and click Open.

The Reverse Java dialog box displays the items you selected.

5. Click the Options tab, then select the Reverse Engineer Deployment Descriptor check box.

6. Click OK.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

7. Click OK.

The Reverse page of the Output window displays the changes that occurred during reverse and the diagram window displays the updated model.

Java Server Pages (JSPs)

Java Server Page (JSP) is an HTML Web page that contains additional bits of code that execute application logic to generate dynamic content.

In an OOM, a JSP is represented as a file object and is linked to a component - of type JSP -. The Java Server Page (JSP) component type allows you to identify this component. Components of this type are linked to a single file object that defines the page.

When you set the type of the component to JSP, the appropriate JSP file object is automatically created, or attached if it already exists. You can see the JSP file object from the Files page in the component property sheet.

JSP Page of the Component

When you set the type of the component to JSP, the JSP page is automatically displayed in the component property sheet.

The JSP page in the component property sheet includes the following properties:

Property	Description
JSP file	File object that defines the page. You can click the Properties tool beside this box to display the property sheet of the file object, or click the Create tool to create a file object
Default template	Extended attribute that allows you to select a template for generation. Its content can be user defined or delivered by default

To modify the default content, edit the current object language from **Language > Edit Current Object Language** and modify the following item: Profile/FileObject/Criteria/JSP/Templates/DefaultContent<%is(DefaultTemplate)%>. Then create the templates and rename them as DefaultContent<%is(<name>)%> where <name> stands for the corresponding DefaultContent template name.

To define additional DefaultContent templates for JSPs, you have to modify the JSPTemplate extended attribute type from Profile/Share/Extended Attribute Types and add new values corresponding to the new templates respective names.

For more information on the default template property, see the definition of TemplateContent in *Creating a JSP with the wizard* on page 409.

Defining File Objects for JSPs

The file object content for JSPs is based on a special template called DefaultContent defined with respect to the FileObject metaclass. It is located in the Profile/FileObject/Criteria/JSP/Templates category of the Java object language. This link to the template exists as a basis,

therefore if you edit the file object, the link to the template is lost - the mechanism is similar to that of operation default bodies.

For more information on the Criteria category, see "Criteria (Profile)" in the Extending your Models with Profiles chapter of the *Customizing and Extending PowerDesigner* manual.

Java Server Page files are identified using the JSPFile stereotype. The server page name is synchronized with the JSP component name following the convention specified in the Value box of the Settings/Namings/JSPFileName entry of the Java object language.

You can right-click a file object, and select Open With text editor from the contextual menu to display the content of the file object.

Creating a JSP with the Wizard

You can create a JSP with the *wizard* that will guide you through the creation of the component. The wizard is invoked from a *class diagram*. It is only available if the language is Java.

You can either create a JSP without selecting any file object, or select a file object beforehand and start the wizard from the Tools menu.

You can also create several JSP of the same type by selecting several file objects at the same time. The wizard will automatically create one JSP per file object: the file objects you have selected in the class diagram become .JSP files.

The wizard for creation of a JSP lets you define the following parameters:

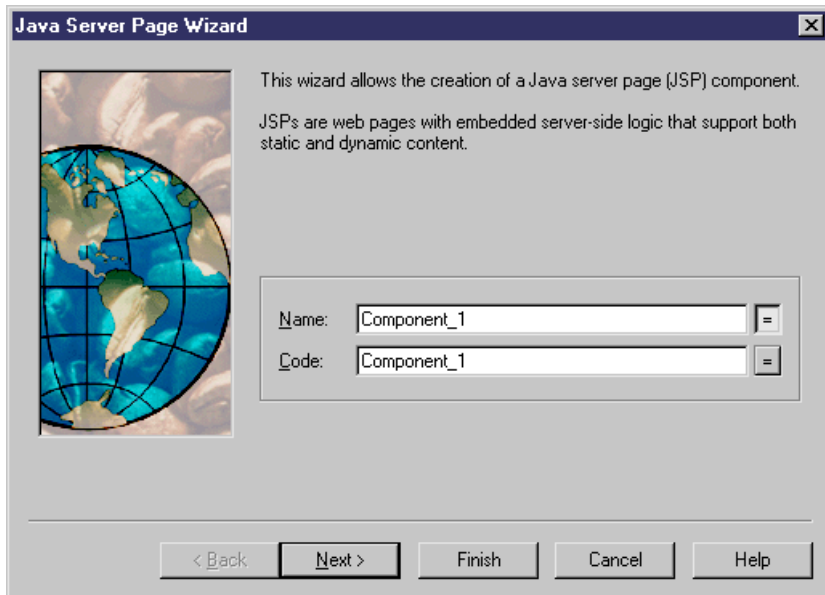

Wizard page	Description
Name	Name of the JSP component
Code	Code of the JSP component
TemplateContent	Allows you to choose the default template of the JSP file object. The TemplateContent is an extended attribute located in the Profile/Component/Criteria/J2EE-JSP category of the Java object language. If you do not modify the content of the file object, the default content remains (see the Contents page of the file object property sheet). All templates are available in the Profile/FileObject/Criteria/JSP/templates category of the Java object language
Create symbol	Creates a component symbol in the diagram specified beside the Create symbol In check box. If a component diagram already exists, you can select one from the list. You can also display the diagram properties by selecting the Properties tool

Creating a JSP with the Wizard

To create a JSP with the wizard:

1. Select **Tools > Create JSP** from a class diagram.

The Java Server Page Wizard dialog box is displayed.

2. Select a name and code for the JSP component and click Next.
3. Select a JSP template and click Next.
4. At the end of the wizard, you have to define the creation of symbols.

When you have finished using the wizard, the following actions are executed:

- A JSP component and a file object with an extension .JSP are created and visible in the Browser. The file object is named after the original default component name to preserve coherence
- If you open the property sheet of the file object, you can see that the Artifact property is selected

For more information on artifact file objects, see *File Object Properties* on page 228.

- You can edit the file object directly in the internal editor of PowerDesigner, if its extension corresponds to an extension defined in the Editors page of the General Options dialog box, and if the <internal> keyword is defined in the Editor Name and Editor Command columns for this extension

Generating JSPs

The generation process generates only file objects with the Artifact property selected.

Generating JSP Web Deployment Descriptor

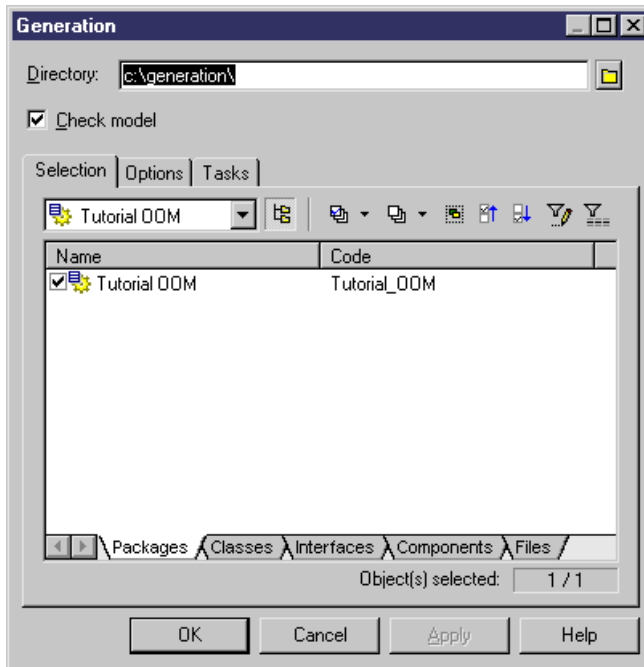

The Web deployment descriptor is an XML file, called web.XML. It is generated in the WEB-INF directory and is independent from the application server.

The Web application deployment descriptor is generated per package. A WAR command available in the Tasks page of the Generation dialog box allows you to build a Web Archive

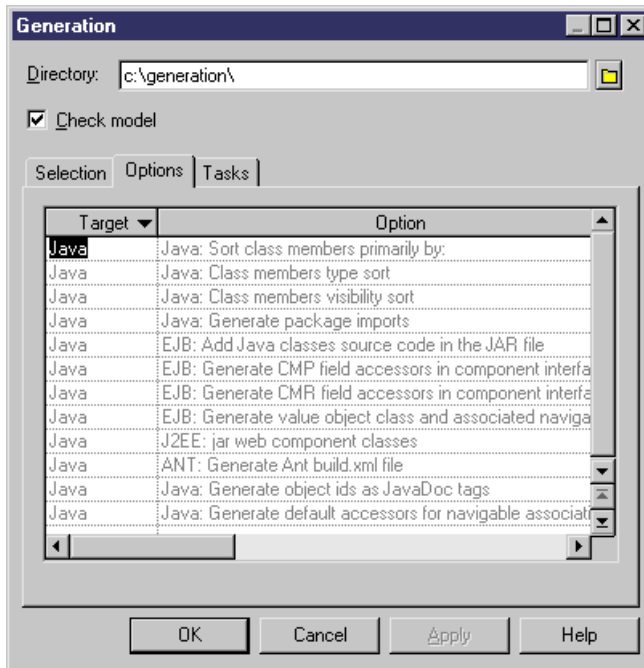

that contains the Web deployment descriptor, in addition to all classes and file objects referenced by JSP components. At the model level, an EAR command is also provided to group all WAR and JAR files generated for a given model inside a single enterprise archive. The EAR contains an additional deployment descriptor generated per model that is called application.XML.

The Web deployment descriptor is available from the Preview page of the package, or the model property sheet.

1. Select **Language > Generate Java Code** to display the Generation dialog box.
2. Select or browse to a directory that will contain the generated files.
3. Click the Selection, then select the objects you need in the different tabbed pages.

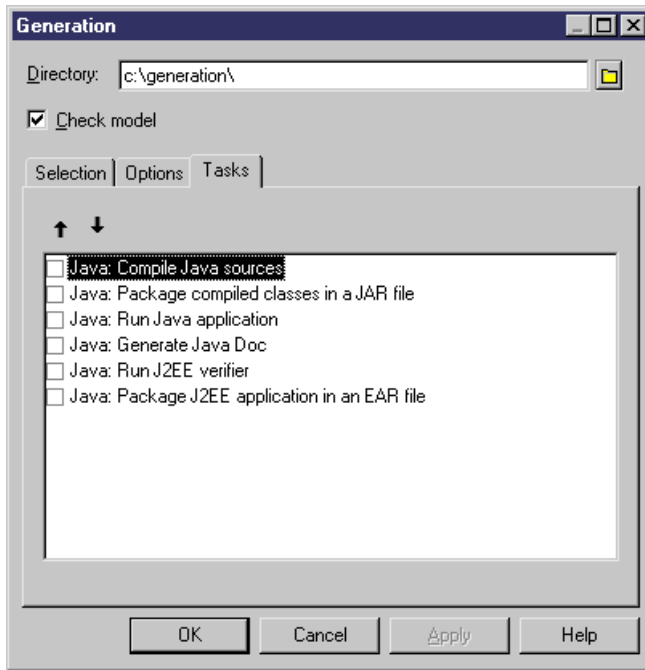

4. Click Apply.
5. Click the Options tab, then specify your generation options in the Options page.

For more information on the generation options, see *Selecting Java Generation Options* on page 416.

6. Click Apply.
7. Click the Tasks tab to display, then select the commands you want to perform during generation in the Tasks page.

For more information on the generation tasks, see *Selecting Java Generation Tasks* on page 418.

You must beforehand set the environment variables from the Variables tab of the General Options dialog box in order to activate them in this page.

For more information on how to set these variables, see "Defining environment variables" section in the Models chapter of the *Core Features Guide*.

8. Click OK.

A progress box is displayed, followed by a Result list. You can use the Edit button in the Result list to edit the generated files individually.

9. Click Close.

The web.XML file is created in the WEB-INF directory and all files are generated in the generation directory.

Reverse Engineering JSPs

You can reverse engineer JSPs code and deployment descriptor into an OOM. The reverse engineering feature reverses the files to create JSP components and reverses the deployment descriptor inside the WAR.

You start reverse engineering JSPs from **Language > Reverse Engineer Java**. Select one of the following Java formats from the Selection page, and select the Reverse Engineer Deployment Descriptor check box from the Options page:

- Java directories
- Class directories
- Archive (.JAR file)

For more information on the Java formats, see *Reverse Engineering Java Code* on page 421.

1. Select Language > Reverse Engineer Java.

The Reverse Java dialog box is displayed.

2. Select Archive from the Reverse list in the Selection page.

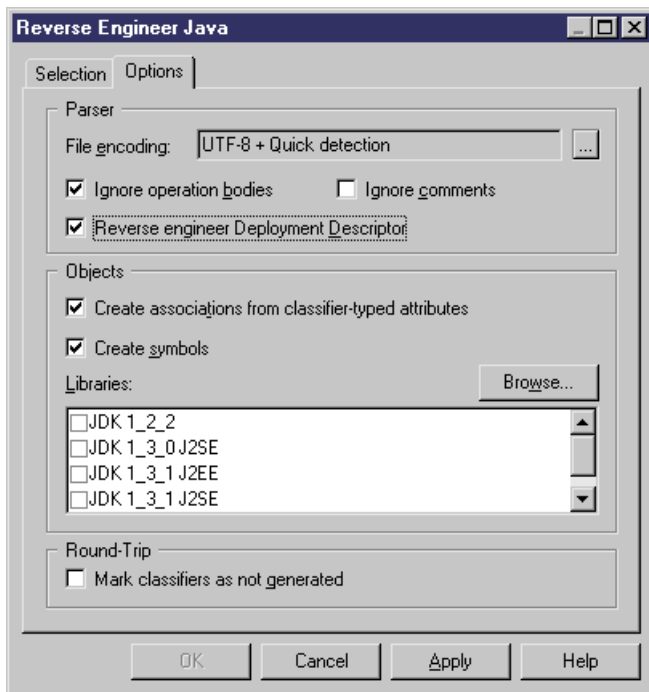

3. Click the Add button.

A standard Open dialog box is displayed.

4. Select the items you want to reverse and click Open.

The Reverse Java dialog box displays the items you selected.

5. Click the Options tab, then select the Reverse Engineer Deployment Descriptor check box.

6. Click OK.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

7. Click OK.

The Reverse page of the Output window displays the changes that occurred during reverse and the diagram window displays the updated model.

Generating Java Code

This section explains some of the features of the Java object language in order to generate Java code from objects in the OOM.

EJB Subfamily

If you work on a Java OOM created in version 9.0, the subfamily of Java is EJB 2.0 and it supports EJB. In later versions, the subfamily of Java has become J2EE, it supports J2EE components (servlets, JSPs and EJB).

You should use the new Java object language provided with the current version to use J2EE components. If you had customized the Java object language in the previous version, you have to apply these changes manually in the new Java object language.

By default the WSDL for Java extended model definition is automatically attached to the model when you select the Java language. This extended model definition supports J2EE 1.3. However, if you want to support J2EE 1.4, you should use the list of extended model definitions to delete the WSDL for Java extended model definition and import the WSDL for Java (J2EE 1.4) extended model definition.

Defining Java Environment Variables

Variables used for Java generation are defined in the General Options dialog box.

For more information on variables and general options, see "Customizing your Modeling Environment" section in the Models chapter of the *Core Features Guide*.

The following variables are created by default when you install PowerDesigner:

Variable	Description	Default
J2EEVERIF	Batch program for verifying if the deployment jar for an EJB is correct	verifier.bat
JAR	Command for archiving java files	jar.exe
JAVA	Command for running JAVA programs	java.exe
JAVAC	Command for compiling JAVA source files	javac.exe
JAVADOC	Command for defining JAVA doc comments	javadoc.exe

You can also add the JAVACLASSPATH variable in this table in order to set the Java classpath, this variable replaces the CLASSPATH environment variable.

Selecting Java Generation Options

You can set the following options, available from the Options page of the Generation dialog box in Java:

Options	For...	Description
Sort class members primarily by	Java	Sorts attributes and operations by type or visibility
Generate package imports	Java	Used to declare import of the whole package
Class members type sort	Java	Sorts attributes and operations by type
Class members visibility sort	Java	Sorts attributes and operations by visibility

Options	For...	Description
Generate object ids as Java-Doc tags	Java	Generates information used for reverse engineering like object identifiers (@pdoid) that are generated as documentation tags. If you do not want these tags to be generated, you have to set this option to False
Generate default accessors for navigable associations	Java	Generates the getter and setter methods for navigable associations
Generate Ant build.xml file	Ant	Generates the build.xml file. You can use this file if you have installed Ant
Generate CMP field accessors in component interfaces	EJB	Generates CMP fields getter and setter operations to EJB interfaces
Generate CMR field accessors in component interfaces	EJB	Generates CMR fields getter and setter declarations in EJB interfaces
Add Java classes source code in the JAR file	EJB	Includes Java classes code in the JAR
Generate value object class and associated navigation methods for CMP Entity Beans	EJB	Generates an additional class named %Component.Code% ValueObject for each CMP bean class and declares all the CMP fields as public attributes. In addition, a getter and a setter are generated in the bean class for each CMR relationship
Jar Web component classes	J2EE	Archives Web component classes in a Jar

You can set Java generation to sort the order in which the attributes and operations of the class in a Java class definition file are displayed. You can sort the order according to either visibility or member type for example.

Primary Sort

You can sort the order according to the visibility or the type.

Option	Result of selection
Visibility	Public attributes and operations are generated before private attributes and operations in the Java file
Type	Attributes and operations are sorted by type whatever their visibility

Visibility Sort

You can sort the visibility order as follows:

Option	Result of selection
Public – Private	Public attributes and operations are generated before private attributes and operations
Private – Public	Private attributes and operations are generated before public attributes and operations
None	Attributes and operations order remains unchanged

Type Sort

You can sort the type order as follows:

Option	Result of selection
Attributes – Operations	Class attributes are generated before the operations
Operations – Attributes	Class operations are generated before the attributes

Generate Package Imports

When a class is used by another class, it is referenced by a class import:

```
import package1.package2.class.
```

The Generate package imports allows you to declare import of the whole package, it saves time whenever many classes of the same package are possibly referenced:

```
import package1.package2.*;
```

Selecting Java Generation Tasks

The following tasks are available from the Tasks page in the Generation dialog box for Java:

Task	Description
Compile Java sources	Starts a compiler using the javac command to compile Java source files
Package compiled classes in a JAR file	Compiles source files and package them in a JAR file
Run Java application	Compiles source files and run the Java application using the java command
Generate Javadoc	Generates Javadoc

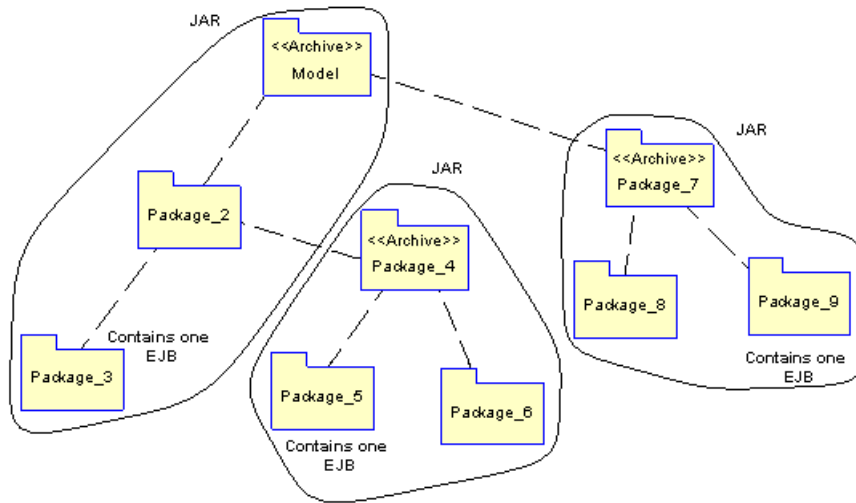

Task	Description
Package J2EE application in an EAR file	Calls commands for building EJB component source, creating a JAR file for Java classes and a deployment descriptor, building the Web component source code, creating an EAR file for Web component classes and a deployment descriptor, and creating an EAR archive containing all generated JAR/WAR files
Run J2EE verifier	Calls commands for building EJB component source code, creating a JAR file for Java classes and a deployment descriptor, building the Web component source code, creating a WAR file for Web component classes and a deployment descriptor, creating an EAR archive containing all generated JAR/WAR files, and running the J2EE verifier on generated archives
WSDL: Compile and package Web Service server-side code into an archive	Calls commands for building EJB and Web component source code, running the WSCcompile tool, creating a WAR file for Web component classes and deployment descriptor, and creating a JAR file for Java classes and deployment descriptor
WSDL: Compile and package Web Service client proxy into an archive	Calls commands for building EJB and Web component source code, running the WSCcompile tool, and creating a WAR file for client-side artifacts

JARs and WARs

There is no constraint over the generation of a JAR or a WAR per package. Only packages with the <<archive>> stereotype will generate a JAR or a WAR when they (or one of their descendant package not stereotyped <<archive>>) contain one EJB (for the JAR), and one servlet or JSP (for the WAR).

The newly created archive contains the package and all of its non-stereotyped descendants. The root package (that is the model) is always considered as being stereotyped <<archive>>.

For example, if a model contains several EJB components in different sub-packages but that none of these packages is stereotyped <<archive>>, a single JAR is created encompassing all packages.

Java Executables

The default compiler command is the javac executable. The default run command for the Java compiler is the java executable.

Those commands are used by default in PowerDesigner but you can customize your commands using any other suitable executable by selecting **Tools > General Options > Variables** and setting your preferences in this page.

Generating Java Files

You generate Java source files from the classes and interfaces of a model. A separate file, with the file extension .java, is generated for each class or interface that you select from the model. A generation log file is also created at the same time. You can only generate Java files from one model at a time.

A Java source can contain several classes, whereas a Java .class can contain only one class. You can compile the .java class files that you generate from an OOM in any Java compiler tool and run your Java application.

1. Select **Language > Generate Java Code** to display the Java generation dialog box.
2. Type a destination directory for the generated file in the Directory box.

or

Click the Select a Path button to the right of the Directory box and browse to select a directory path.

3. Click the Selection tab, then select the objects to include in the generation from the tabbed pages at the bottom of the page.

Note: All classes of the model, including those grouped into packages, are selected and displayed by default. You use the Select tools to the right of the Folder Selection list to modify the selection. The Include Sub-Packages tool allows you to include all classes located within packages.

4. Click the Options tab to display the Options page.
5. <optional> Select the Check Model check box if you want to verify the validity of your model before generation.
6. Select a value for each required option.
7. Click the Tasks tab, then select the required task(s).
8. Click OK to generate.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation page of the Output window, located in the bottom part of the main window.

All Java files are generated in the destination directory.

Reverse Engineering Java Code

You can reverse engineer files that contain Java classes into an OOM. For each existing class in a Java file, a corresponding class is created in the OOM, with the same name and containing the same information.

When you reverse engineer a Java class that already exists in a model, a Merge Model window will open, allowing you to specify whether to replace existing classes, or to retain the existing class definitions in the model.

1. Select **Language > Reverse Engineer Java**. to open the Reverse Engineer Java dialog box:

2. Select one of the following file formats from the Reverse engineer list:
 - *Java files* (.java) - Files contains one or several class definitions.
 - *Java directories* - Folders containing Java files. All the .java files, including those contained in sub-directories will be reverse engineered. Each sub-directory becomes a package within the model. As Java files in the same directory are often interdependent, if you do not reverse engineer all the files in the directory, your model may be incomplete.
 - *Class files* (.class) – Compiled files containing the definition of a single class with the same name as the file. Each sub-directory becomes a package within the model.
 - *Class directories* – Folders containing class files. All the .class files, including those contained in sub-directories will be reverse engineered.
 - *Archives* (.zip, .jar) - Compressed files containing definitions of one or several classes. PowerDesigner creates a class for each class definition in the .jar or .zip file. The following files are not reverse engineered: manifest.mf, web.xml, ejb-jar.xml, and *.jsp. Other files are reverse engineered as files with the Artifact property set to true so that they can be generated later. Files are reverse engineered in packages corresponding to the directory structure found in the archive.
3. Click the Add button to browse to and select the files or directories to reverse, and then click Open to return to the Reverse Java dialog box, which now displays the selected files.

You can repeat this step as many times as necessary to select files or directories from different locations.

You can right-click any of the files and select Edit from the contextual menu to view its contents in an editor.

4. [optional] Click the Options tab and specify any appropriate reverse engineering options. For more information about these options, see *Reverse Engineer Java Options tab* on page 423

Note: You can choose to reverse .java source files without their code body for visualization or comparison purposes, or to limit the size of your model if you have a very large number of classes to reverse engineer. To do this, select the Ignore operation body option.

5. Click OK to begin the reverse engineering process. If the model in which you are reverse engineering already contains data, the Merge Models dialog box will open to allow you to specify whether to control whether existing objects will be overwritten.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

PowerDesigner creates a class in the model for each class definition in the reversed files. The classes are visible in the Browser and, by default, symbols are created in one or more diagrams

Reverse Engineer Java Options Tab

The options tab allows you to specify various reverse engineering options.

The following Java reverse engineering options are available. Note that some may be disabled depending on the type of Java files being reversed:

Option	Result of selection
File encoding	Specifies the default file encoding of the files to reverse engineer.
Ignore operation bodies	Reverses classes without including the body of the code. This can be useful when you want to reverse objects for visualization or comparison purposes, or to limit the size of your model if you have a very large number of classes to reverse.
Ignore comments	Reverses classes without including code comments.
Reverse engineer Deployment Descriptor	Reverses components with deployment descriptor. For more information, see <i>Reverse Engineering EJB Components</i> on page 391, <i>Reverse Engineering Servlets</i> on page 406, and <i>Reverse Engineering JSPs</i> on page 414.
Create associations from classifier-typed attributes	Creates associations between classes and/or interfaces.
Create symbols	Creates a symbol for each object in the diagram. If this option is not selected, reversed objects are only visible in the browser.
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>
Mark classifiers as not generated	Specifies that reversed classifiers (classes and interfaces) will not be generated from the model. To subsequently generate the classifier, you must select the Generate check box in its property sheet.

Reverse Engineering Java Code Comments

When you reverse engineer Java files, some comments may change form or position within the code.

Comment in original Java file	After reverse
Before the import declarations	Goes to header
Beginning with /*	Begins with //
At the end of the file below all the code	Goes to footer
Within a class but not within an operation	Is attached to the attribute or operation that immediately follows it

CHAPTER 14 Working with the Eclipse Modeling Framework (EMF)

PowerDesigner supports modeling in the EMF language including round-trip engineering.

The Eclipse Modeling Framework (EMF), is a modeling framework and code generation facility for building tools and other applications based on a structured data model. An EMF model provides a simple model of the classes and data of an application and is used as a metadata definition framework in lots of Eclipse based tools, including Sybase DI and Sybase WorkSpace.

For more information on EMF, see the EMF documentation and tutorials at <http://www.eclipse.org/emf>.

EMF Objects

The following objects are available in an OOM targeted for EMF.

EPackages

PowerDesigner models EMF EPackages as standard UML packages, but with additional properties.

EPackage property sheets contains all the standard package tabs along with the EMF tab, the properties of which are listed below:

Property	Description
Namespace prefix	Used when references to instances of the classes in this package are serialized..
Namespace URI	Appears in the xmlns tag to identify this package in an XMI document.
Base package name	Contains the generated code for the model.

For information about creating and working with packages, see *Packages (OOM)* on page 48.

EClasses, EEnums, and EDataTypes

PowerDesigner models EMF EClasses as standard UML classes, and EEnums and EDataTypes as standard UML classes with an Enum and an EDataType stereotype, respectively.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

EClass, Eenum, and EDataType property sheets contain all the standard class tabs along with the EMF tab, the properties of which are listed below:

Property	Description
Instance Class Name	Specifies the data type instance class name.

EAnnotations

PowerDesigner models EMF EAnnotations as standard UML classes, with an AnnotationType stereotype.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

EAnnotation property sheets contain all the standard class tabs along with the EMF tab, the properties of which are listed below:

Property	Description
References	Specifies the EMF annotation references.
URI	Specifies the EMF annotation source.

EAttributes and EEnumLiterals

PowerDesigner models EMF EAttributes and EEnumLiterals (EAttributes belonging to EEnums) as standard UML attributes, but with additional properties.

For information about creating and working with attributes, see *Attributes (OOM)* on page 65.

EAttribute and EEnumLiteral property sheets contains all the standard attribute tabs along with the EMF specific tabs listed in the sections below.

Property	Description
Unique	Specifies that the attribute may not have duplicates.
Unsettable	Generates an unset method to undo the set operation.
Ordered	Specifies that the attribute is ordered.

EReferences

PowerDesigner models EMF EReferences as standard UML associations, but with additional properties.

For information about creating and working with associations, see *Associations (OOM)* on page 86.

EReference property sheets contains all the standard association tabs along with the EMF tab, the properties of which are listed below:

Property	Description
Unique	Specifies that the selected role may not have duplicates.
Resolve proxies	Resolves proxies if the selected role is in another file.
Unsettable	Specifies that the selected role cannot be set.

EOperations and EParameters

PowerDesigner models EMF EOperations and EParameters as standard UML operations and operation parameters.

For information about creating and working with operations, see *Operations (OOM)* on page 76.

Generating EMF Files

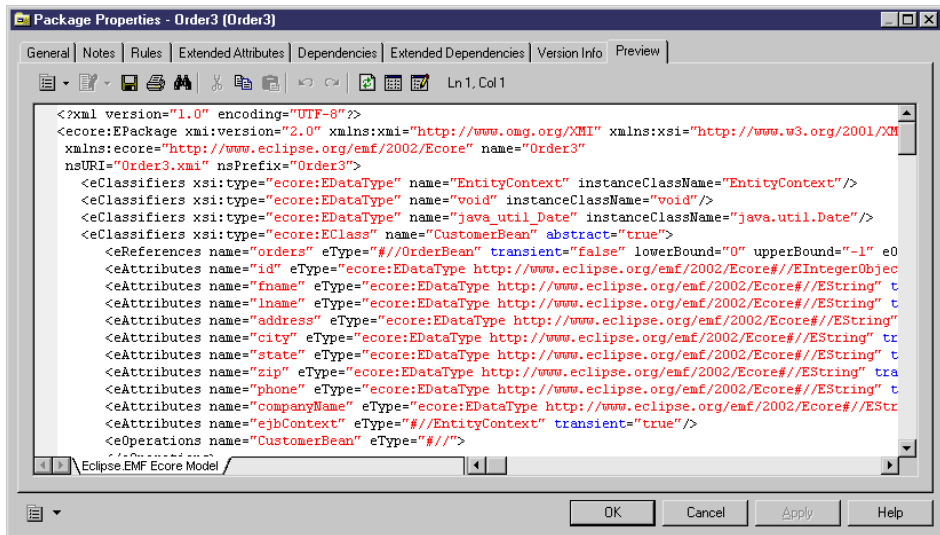

PowerDesigner can generate EMF .ecore and .genmodel files.

1. Select **Language > Generate EMF Code** to open the Generation dialog box:
2. Enter a directory in which to generate the files and specify whether you want to perform a model check.
3. [optional] On the Selection tab, specify the objects that you want to generate from. By default, all objects are generated, and PowerDesigner remembers for any subsequent generation the changes you make.

Note: Although you can create all the standard UML diagrams and their associated objects, you can only generate packages, classes, and interfaces.

4. [optional] Click the Options tab and specify the EMF version that you want to generate for.
5. Click OK to begin generation.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation tab of the Output window, located in the bottom part of the main window.

Reverse Engineering EMF Files

In order to reverse engineer EMF files into an OOM, you must use the PowerDesigner Eclipse plugin, and also have installed the EMF plugin.

1. Select **Language > Reverse Engineer EMF** to open the Reverse Engineer OOM from EMF file dialog box.
2. Click one of the following buttons to browse to .ecore, .emof, or .genmodel files to reverse engineer:
 - Browse File System
 - Browse Workspace
3. Select the files to reverse engineer and click Open (or OK) to add them to the Model URIs list.
4. Click Next to go to the Package Selection page, and select the packages to reverse engineer.
5. Click Finish to begin the reverse engineering.

If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The packages are added to your model.

CHAPTER 15 Working with IDL

PowerDesigner supports modeling in the Interface Definition Language.

IDL stands for Interface Definition Language. It was defined for the Common Object Request Broker Architecture (CORBA) to enable client/server object interaction.

The IDL language is independent from the platform you are working on. In this manual, we refer to version 2.4 of the IDL-CORBA specification, and we support the concepts defined in the UML Profile for CORBA Specification from the Object Management Group (OMG).

IDL Objects

PowerDesigner supports modeling for all IDL objects.

Interfaces

PowerDesigner represents CORBA interfaces as standard classes with the `<<CORBAInterface>>` stereotype or as standard interfaces (to which a `<<CORBAInterface>>` stereotype is automatically applied). IDL interface properties are represented as follows:

IDL concept	PowerDesigner implementation
Inheritance between interfaces	Generalization link between classes with <code><<CORBAInterface>></code> stereotype
Readonly attribute	Readonly stereotype for attribute
Local interface	isLocal extended attribute set to True
Abstract interface	Abstract property selected in class property sheet
Interface declaration	Use inner link between <code><<CORBAInterface>></code> class and other items

Note: You can draw associations between interfaces. Use an inner link to declare an item inner to another.

In the following example, the composition link indicates that an attribute in TestInterface uses the interface TestStruct as data type. The declaration inside the interface is performed with an inner link.

```

interface TestInterface {
  struct TestStruct {
    string member1;
  };

  attribute string StringA;
  attribute TestInterface::TestStruct MyStructAttr;
  void OperationA(inout TestStruct t, in string str);
  boolean OperationB(inout TestStruct t);
};
  
```

Modules

PowerDesigner represents CORBA modules as packages bearing the <<CORBAModule>> stereotype.

One IDL file is generated per package. The directory hierarchy follows the module hierarchy (and not the package hierarchy), so that only <<CORBAModule>> stereotyped packages are mapped onto file directories. #include directives are generated based on <<include>> stereotyped dependencies between packages and based on class shortcuts defined in a given package

Data Types

PowerDesigner represents CORBA data type as classes bearing the <<CORBAPrimitive>> stereotype, and fixed data types as classes bearing the <<CORBAFixed>> stereotype.

When you apply the <<CORBAFixed>>stereotype, the following extended attributes are automatically added to the class, for which you must define values:

- *digits*: indicates the number of digits of the fixed-point decimal number
- *scale*: indicates the scale of the fixed-point decimal number

```

typedef fixed<8, 3> Class_1;
  
```

General Constants

PowerDesigner represents CORBA general constants (values defined independently of any object and likely to be reused) as attributes created in a class, where both the class and the attribute bear the `<<CORBAConstants>>` stereotype.

```
const char red = 13325;
const char blue = 14445;
const long green = 26664;
```

Interface Constants

PowerDesigner represents CORBA interface constants (values defined for a specific interface) as attributes bearing the `<<CORBAConstants>>` stereotype, which are created in the interface where they will be used.

```
interface screen {
  const short background = blue;
  const short fields = green
}
```

Typedefs

PowerDesigner represents CORBA simple typedefs as classes bearing the `<<CORBATypedef>>` stereotype. The typedef class should be linked to a class with the `<<CORBAPrimitive>>`, `<<CORBAStruct>>` or `<<CORBAUnion>>` stereotype through a generalization link in order to define the type of data.

```
typedef num identifier;
```

Sequences, Anonymous Sequences, and Sequences in Structs

PowerDesigner represents CORBA sequences as classes bearing the `<<CORBASequence>>` stereotype. The upper bound of the sequence is specified by its *UpperBound* extended attribute, and its type is defined in another class linked to it by an association.

```
typedef sequence< string > name_lastname;
```

To avoid defining directly a type for a sequence to design sequence imbrication, use the `<<CORBAAnonymousSequence>>` stereotype.

```
typedef sequence< sequence< string > > Election_list;
```

To create a sequence in a struct, apply the `<<CORBAAnonymousSequence>>` stereotype to the sequence class.

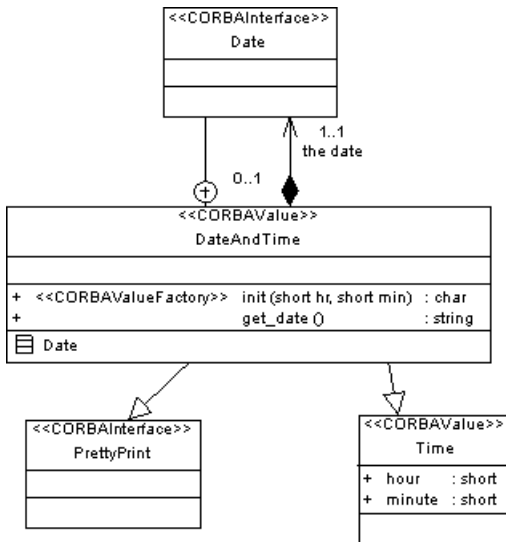

```
struct Customer {
    string name_lastname;
    long age;
    sequence< string > w;
};
```

Valuetypes and Custom Valuetypes

PowerDesigner represents CORBA valuetypes as classes bearing the `<<CORBAValue>>` stereotype and custom valuetypes as classes bearing the `<<CORBACustomValue>>` stereotype. You can further define the valuetype as follows:

- Inheritance between valuetypes has to be designed as a generalization between two valuetype classes
- The interface supported by a value type is the one linked to the valuetype class with a generalization
- Members of a valuetype are linked with a composition to the valuetype
- You can declare an interface inside a valuetype using an inner link
- Boolean extended attribute *Istruncatable* allows you to specify if the valuetype is truncatable or not
- A value type factory operation is represented using an operation with the `<<CORBAValueFactory>>` stereotype

- Code for DateAndTime:

```

valuetype DateAndTime : Time supports PrettyPrint {
    public DateAndTime::Date the date;
    factory init(in short hr, in short min);
    string get_date();
};
  
```

Boxed Values

PowerDesigner represents CORBA boxed values as classes bearing the `<<CORBABoxedValue>>` stereotype. Since the boxed value does not support inheritance, or operations, you should use a class with the `<<CORBAAnonymousSequence>>` stereotype to associate a boxed value with an interface.

```

valuetype OptionalNameSeq sequence< myName >;
  
```

Enums

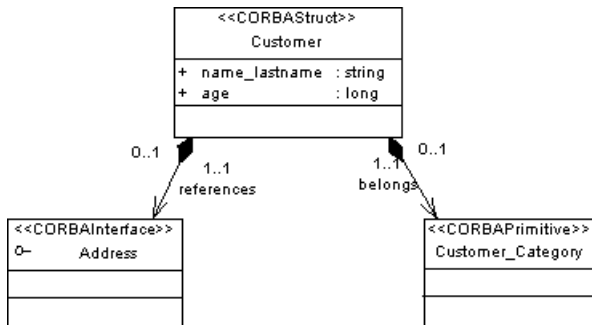

PowerDesigner represents CORBA enums as classes bearing the `<<CORBAEnum>>` stereotype, and enum elements as attributes bearing the `<<CORBAEnum>>` stereotype.

Structs

PowerDesigner represents CORBA struct types as classes bearing the `<<CORBAStruct>>` stereotype. You can mix attribute types in the struct class.

```
struct Customer {
  string name_lastname;
  long age;
};
```

You use composition links to define complex struct classes as defined in the following example:

```
struct Customer {
  string name_lastname;
  long age;
  Address references;
  Customer_Category belongs;
};
```

To define a struct inside another struct, create two classes with the `<<CORBAStruct>>` stereotype, add a composition between classes and use the *inner link* feature to declare one class as inner to the other.

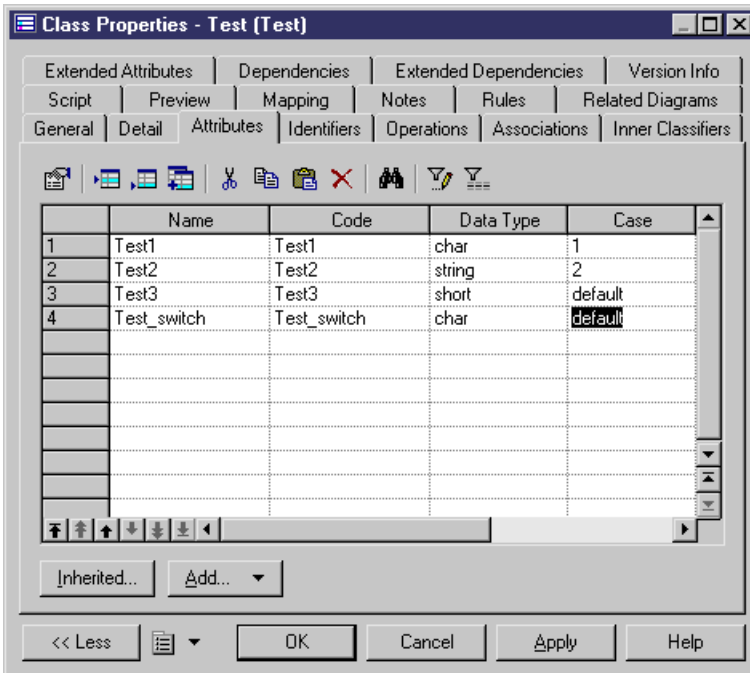

```
struct A {
  struct B {
    short c;
    long d;
  } e, z;
  string x;
};
```

Unions

PowerDesigner represents CORBA unions as classes bearing the `<<CORBAUnion>>` stereotype. Each attribute in a union represents a case, the *Case* extended attribute (in Profile \Attribute\Criteria\IDL union member\Extended Attributes) contains the case default value.

To define the *switch* data type, the discriminant data type for union cases, you have to add an attribute named `<class name>_switch` to the list of union attributes.

```
union Test switch(char) {
  case 1:
    char Test1;
  case 2:
    string Test2;
  default:
    short Test3;
};
```

You can use an enum or a struct as a case in the union using a composition association.

```
union Customer switch(short) {
  case XYZ:
```

```

char Last_Name;
case ZYX:
char Name;
default:
Identification uses;
};

```

The name of the attribute is on the association role and the case is on the association.

You can use an enum or a struct as a switch data type using a composition association. In this situation, the composition role is used as switch attribute for the union.

```

union Screen switch(Colors) {
case red:
short background;
case blue:
short foreground;
};

```

If you do not use the composition role as switch attribute, you still have to define a switch attribute in the Union.

Arrays

PowerDesigner represents CORBA arrays as classes bearing the *<<CORBAArray>>* stereotype. You must link the array class with another class representing the array type (use the *<<CORBAPrimitive>>* stereotype to define the type), and define the array dimension in the Dims extended attribute of the array class, a comma-separated list of the dimensions (integer values) of the array. It is used in place of the index<i> qualifiers on the associationEnd specified in the CORBA profile.

In the following example, array 2D_array uses string data type set to 10:

```

typedef string 2D_array[10];

```

You can use a class with the *<<CORBAAnonymousSequence>>* stereotype to avoid directly defining a type for an array for a sequence.

```

typedef sequence< string > 2D_array[10];

```

To define arrays for a union or a struct attribute, you have to use the multiplicity properties of the attribute.

```
union Customer switch(short) {
  case XYZ:
    char Last_Name[ 30 ];
  case ZYX:
    char Name[ 20 ];
};
```

You can also use the association multiplicity when the union or struct is linked with another class. The association role and multiplicity will become array attributes of the union or struct classes:

```
struct Client {
  char Name[30];
  short Age[3];
  European_Client European attributes[5];
};
```

Exceptions

PowerDesigner represents CORBA exceptions as classes bearing the <<CORBAException>> stereotype, where the class is declared as inner to the interface likely to raise the exception.

The list of exceptions is defined in the Exceptions tabbed page in the Implementation page of an operation, with *no enclosing parentheses*.

```
interface TEX {
  exception Badness2000 {
    string err_msg;
  };

  void process_token(in string tok) raises (Badness2000);
};
```

```

struct AdminLimit {
    PropertyName name;
    PropertyValue value;
};
  
```

```

exception AdminLimitExceeded {
    AdminLimit admin_property_error;
};
  
```

Generating for IDL

IDL generation produces files with the .idl extension. One IDL file is generated per package.

A generation log file is also created after generation.

You can select the Check model option in the Options page of the Generation dialog box before starting generation.

For more information on how to design objects for IDL generation, see *Chapter 15, Working with IDL* on page 431.

1. Select **Language > Generate IDL-CORBA Code** to display the Generation dialog box.
2. Type a destination directory for the generated file in the Directory box.

or

Click the Select a Path button to the right of the Directory box and browse to select a directory path.

3. Select the items to include in the generation from the Selection page.
4. Click the Options tab to display the Options page.
5. <optional> Select the Check Model check box if you want to verify the validity of your model before generation.
6. Select a value for each required option.

7. Click the Tasks tab, then select the required task(s).
8. Click OK to generate.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation page of the Output window, located in the bottom part of the main window.

All IDL files are generated in the destination directory.

Reverse Engineering IDL Files

You can reverse engineer IDL files to create classes and interfaces with their attributes and operations in a class diagram.

Reverse-engineering IDL files is subject to the following limitations:

- Pre-processing - When a # symbol is displayed at the beginning of a line, the reverse feature processes both "if" and "else" values during reverse.
- The following tags are not reversed:
 - fixed <8, 4>
 - fixed <8, 2>
 - sequence <short, 4>
 - sequence
 - [wire_marshall(wireVARIANT)]

An example is shown below:

```
struct bar {
    fixed <8, 4> high_scale;
    fixed <8, 2> low_scale;
};

struct bar {
    long val;
    sequence <short, 4> my_shorts;
};

typedef sequence<LinkKind>LinkKinds;
typedef [wire_marshall( wireVARIANT )] struct tagVARIANT VARIANT;
```

Note: You can right-click the files to reverse engineer and select the Edit command to view the content of your files. To use this command you have to associate the file extension with an editor in the General Options\Editor dialog box.

1. Select **Language > Reverse Engineer IDL** to display the Reverse IDL dialog box.
2. Select reverse engineer files or directories from the Reverse Engineering dropdown listbox.
3. Click the Add button in the Selection page.

A standard Open dialog box is displayed.

4. Select the items or directory you want to reverse engineer, then click the Open button.

Note: You select several files simultaneously using the ctrl or shift keys. You cannot select several directories.

The Reverse IDL dialog box displays the items you selected.

5. Select reverse engineering options in the Options page.

Option	Result of selection
Create symbols	Creates a symbol for each reversed IDL object in the diagram. Otherwise, reversed objects are visible only in the browser
Mark classifiers not to be generated	Reversed classifiers (classes and interfaces) will not be generated from the model. To generate the classifier, you must select the Generate check box in its property sheet
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>

6. Click OK.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The classes and interfaces are added to your model. They are visible in the diagram and in the Browser. They are also listed in the Reverse page of the Output window, located in the lower part of the main window.

CHAPTER 16 Working with PowerBuilder

PowerDesigner supports the modeling of PowerBuilder programs including round-trip engineering.

PowerBuilder is an object oriented development tool. Most of its components are designed as objects with properties, methods and events that can be mapped to UML classes as defined in an OOM.

PowerDesigner supports PowerBuilder objects stored in a .PBL file. Dynamic PowerBuilder Libraries (PBD) are not supported. You can map classes to PowerBuilder objects using specific stereotypes. Some PowerBuilder objects support full-featured mapping with an OOM class, some do not.

Full-featured Mapping

This section describes the mapping between PowerBuilder and OOM objects for fully supported PowerBuilder objects.

Application

You design a PowerBuilder application using a class with the `<<application>>` stereotype.

Application properties are defined as follow:

PB application property	designed as
Instance variable	Attribute
Shared variable	Static attribute
Global variable	Attribute with <code><<global>></code> stereotype
Property	Attribute with <code><<property>></code> stereotype
External function	Operation with <code><<external>></code> stereotype
Function	Operation
Event	Operation with <code><<event>></code> stereotype or operation with non-null event name
Structure in object	Inner class with <code><<structure>></code> stereotype

Structure

You design a PowerBuilder structure using a class with the `<<structure>>` stereotype.

The members of the structure are designed with class attributes.

Function

You design a PowerBuilder function using a class with the `<<function>>` stereotype. This class should also contain one operation.

The structures in a function are designed with `<<structure>>` inner classes linked to the class.

User Object

You design a PowerBuilder user object using a class with the `<<userObject>>` stereotype.

User objects properties are defined as follow:

PB user object property	designed as
Control	inner class with <code><<control>></code> stereotype
Instance variable	Attribute
Shared variable	Static attribute
Property	attribute with <code><<property>></code> stereotype
Function	Operation
Event	operation with <code><<event>></code> stereotype or operation with non-null event name
Structure in object	inner class with <code><<structure>></code> stereotype

Proxy

You design a PowerBuilder proxy using a class with the `<<proxyObject>>` stereotype.

Instance variables of the proxy are designed with class attributes.

Proxy functions are designed with operations.

Window

You design a PowerBuilder window using a class with the `<<window>>` stereotype.

Window properties are defined as follow:

PB window property	designed as
Control	inner class with <code><<control>></code> stereotype

PB window property	designed as
Instance variable	Attribute
Shared variable	Static attribute
Property	Attribute with <<property>> stereotype
Function	Operation
Event	Operation with <<event>> stereotype or operation with non-null event name
Structure in object	Inner class with <<structure>> stereotype

Minimal Mapping

The following PowerBuilder objects do not support full-featured mapping with PowerDesigner classes:

PowerBuilder	PowerDesigner
Query	<<query>> class
Data window	<<dataWindow>> class
Menu	<<menu>> class
Project	<<project>> class
Pipe line	<<pipeLine>> class
Binary	<<binary>> class

These PowerBuilder objects are reverse engineered as classes with the corresponding PowerBuilder stereotype. Their properties are not mapped to PowerDesigner class properties, and their symbol is a large PowerBuilder icon.

For more information on PowerBuilder reverse engineering, see *Reverse Engineering PowerBuilder* on page 451.

Selecting a PowerBuilder Version

If you have different versions of PowerBuilder installed on your machine PowerDesigner uses by default the most recent version.

If you want to work on an earlier version of PowerBuilder, you can select a version in the generation and reverse engineering dialog boxes.

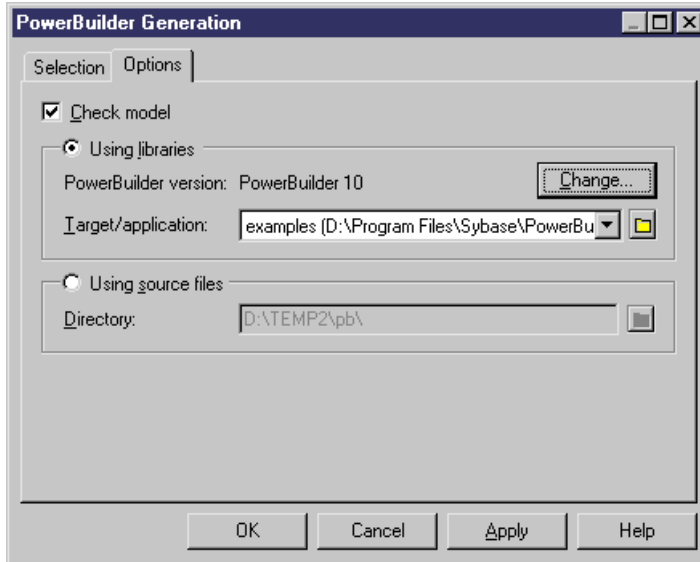

Selecting a PowerBuilder Version During Generation

To select a PowerBuilder version during generation:

1. Select **Language > Generate PowerBuilder**.

The generation dialog box is displayed.

2. Click the Options tab, then select the Using Libraries radio button and select a target or an application.

3. Click the Change button.

The Set PowerBuilder Version dialog box is displayed.

4. Select a PowerBuilder version in the list.

5. Click OK.

The current PowerBuilder version is updated.

Selecting a PowerBuilder Version During Reverse Engineering

To select a PowerBuilder version during reverse engineering:

1. Select **Language > Reverse Engineer PowerBuilder**.

The reverse engineer dialog box is displayed.

2. Select files, libraries or directories to reverse engineer in the Reverse Engineer box.

3. Click the Change button.

The Set PowerBuilder Version dialog box is displayed.

4. Select a PowerBuilder version in the list.

5. Click OK.

The current PowerBuilder version is updated.

Generating for PowerBuilder

This section explains how PowerDesigner objects are generated and how to define the PowerBuilder version you are currently using and generation options for PowerBuilder.

Generated Objects

Some of the generated objects support a full-featured mapping with an PowerBuilder objects, some do not

Full-featured Mapping

During generation, each class is generated as a PowerBuilder supported object depending on its stereotype. The class script is built by templates defined in the PowerBuilder object language. There is one template, called *definition*, for each stereotype corresponding to the supported PowerBuilder objects. Modifying the template code may affect generation.

If a class has no stereotype, it is generated as a User object.

For more information on fully supported PowerBuilder objects, see *Full-featured mapping* on page 443.

Minimal Mapping

For objects not fully supported by PowerDesigner, all the properties (attributes, operations, and others) are lost during generation. The *definition* template is used, but for these objects it is restricted to the evaluation of the header property of the class (%Header%).

For more information on partially supported PowerBuilder objects, see *Minimal mapping* on page 445.

Operation Generated Header

If the operation extended attribute *GenerateHeader* is set to true, the operation header will be generated. This attribute is set to true for any new operation. You can force header generation for all operations in a model by setting the *ForceOperationHeader* extended attribute to true.

Operation headers are generated in the following way:

```
//<FuncType>: <Operation signature>
//Description: <Operation comment line1>
//          <Operation comment line2>
//Access: <visibility>
//Arguments: <parameter1 name> - <parameter1 comment line1>
//           <parameter1 comment line2>
//           <parameter2 name> - <parameter2 comment>
//Returns: <Return comment>
//          <Return comment2>
```

Header item	Corresponds to
FuncType	Function, Subroutine or Event
Description	Comment typed in operation property sheet
Access	Visibility property in operation property sheet
Arguments	Parameter(s) name and comment
Returns	Value of ReturnComment extended attribute in operation property sheet
User-defined comment	Value of UserDefinedComment extended attribute in operation property sheet

Generating Events

You can generate events as follows:

- To generate a *custom event handler*: you have to create an operation and set a value to the EventID extended attribute
- To generate a *standard event handler*: you have to create an operation and select an event value in the Language Event list in the operation property sheet
- To generate a *user-defined event handler*: you have to create an operation and select the <<event>> stereotype. The Language Event list must remain empty

When the EventID extended attribute has a value, the operation is generated as a custom event handler, although it has a name defined in the Language Event list or the <<event>> stereotype.

Selecting PowerBuilder Generation Options

PowerBuilder is a specific language that uses its own generation options. You can generate PowerBuilder objects from the classes of an OOM using the following generation options in the PowerBuilder Generation dialog box:

- Using libraries
- Using source files

You can also select the Check Model check box to verify the model before generation and stop generation if an error is found.

Using Libraries

You have to select a target or an application from the Target/Application list. The following situations occur during generation:

Generated object	Generation result
Package with specified library path (defined in an extended attribute during reverse engineering)	Generated in corresponding library from target/application library list
Package at the root of the model without library path	Generated in a new library at the same level as target/application library
Child package without library path	Generated in parent package
Object at the root of the model	Generated in the target/application library

For more information on PowerBuilder reverse engineering, see *Reverse Engineering PowerBuilder* on page 451.

Note: this mode is not available if you do not have PowerBuilder installed on your machine.

Using Source Files

You have to define a generation directory.

Classes Defined at the Model Level are generated as source files in the specified directory.

Classes Defined in Packages are generated as source files in sub-directories.

You will then have to import the generated objects into PowerBuilder.

Generating Objects for PowerBuilder

To generate objects for PowerBuilder

1. Select **Language > Generate PowerBuilder** to display the PowerBuilder Generation dialog box.
2. Select a model or package from the Folder Selection list.
3. Select the classes to generate from the list.

Note: All classes of the model are selected and displayed by default. Use the Select tools to the right of the Folder Selection list to modify the selection. The Include Sub-Packages tool allows you to include all objects located within packages.

4. Click the Options tab to display the Options tab.
5. <optional> Select the Check Model check box if you want to verify the validity of your model before generation.
6. Select the required options.
7. Click OK to generate.

A PowerBuilder user object is generated in the PowerBuilder application for each selected class.

Reverse Engineering PowerBuilder

This section explains how PowerBuilder objects are reverse engineered and how to define reverse engineering options for PowerBuilder.

Reverse Engineered Objects

You can reverse engineer into an OOM, objects stored in a .PBL file or exported by PowerBuilder into files. Some of the reverse engineered objects support a full-featured mapping with an OOM class, some do not.

Libraries

Each PowerBuilder library is reversed as a package in the resulting OOM. The path of the library is stored in an extended attribute attached to the package.

Objects reverse engineered from a library are created into the corresponding package in PowerDesigner.

Full-featured Mapping

During reverse engineering, new classes with stereotype corresponding to the PowerBuilder objects they come from are created. The symbol of these classes displays an icon in the upper left corner:

For more information on fully supported PowerBuilder objects, *Full-featured mapping* on page 443.

Minimal Mapping

PowerBuilder objects not fully supported in PowerDesigner are reverse engineered as classes with the corresponding PowerBuilder stereotype. However, their properties are not mapped to PowerDesigner class properties, and their symbol is a large PowerBuilder icon.

The source code of these objects is retrieved without any parsing and stored in the class header, as displayed in the Script\Header tab of the class; it will be used in the same way during generation.

For more information on partially supported PowerBuilder objects, see *Minimal mapping* on page 445.

Operation Reversed Header

Reverse engineering processes the first comment block of the function between two lines of slash characters.

```

////////////////////////////////////
/////
// <FuncType>: <Operation signature>
// Description: <Operation comment line1>
//           <Operation comment line2>
// Access: <visibility>
// Arguments: <parameter1 name> - <parameter1 comment line1>
//           <parameter1 comment line2>
//           <parameter2 name> - <parameter2 comment>
// Returns: <Return comment>
//           <Return comment2>
////////////////////////////////////
/////

```

If all generated keywords are found, the block will be removed and relevant attributes will be set:

Keywords attribute	Corresponding operation attribute
FuncType, Subroutine, Event	Name
Description	Operation comment
Access	Visibility property
Arguments	Parameter(s) name and comment
Returns	Value for ReturnComment extended attribute
User-defined comment	Value for UserDefinedComment extended attribute
GenerateHeader	Set to True
Other function comments	Kept in operation body

Otherwise, the function comments are kept in the operation body and the GenerateHeader extended attribute set to false.

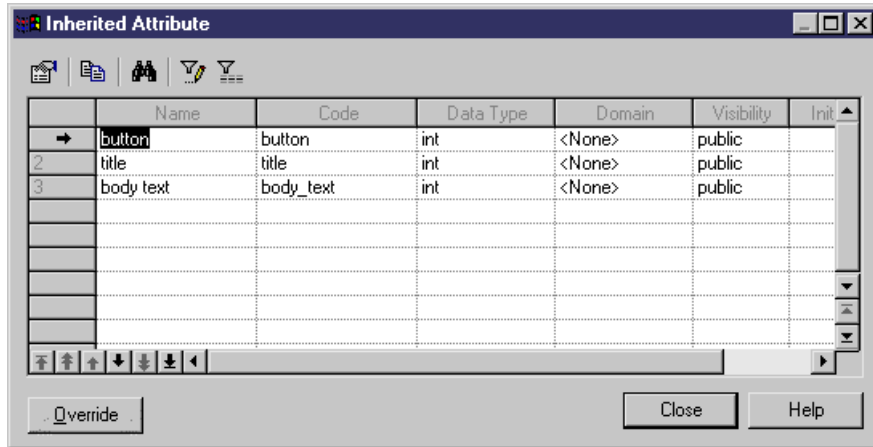

Overriding Attributes

When a class inherits from another class, non-private inherited attributes can be defined as properties of the child class, allowing the user to define initial values in the child class.

1. Open the property sheet of a child class, and display the attribute tab.
2. Click the Inherited button.

The Inherited Attributes dialog box is displayed. It contains the attributes of the parent class.

3. Select one or several attributes in the list.
4. Click the Override button.

5. Click Close.

The attributes appear in the child class list of attributes. You can modify their initial value in the corresponding column.

6. Click OK.

Selecting PowerBuilder Reverse Engineering Options

You define the following PowerBuilder reverse engineering options from the Reverse Engineer PowerBuilder dialog box:

Option	Result of selection
Ignore operation body	Reverses PowerBuilder objects without including the body of the code
Ignore comments	Reverses PowerBuilder objects without including code comments
Create symbols	Creates a symbol in the diagram for each object. Otherwise, reversed objects are visible only in the browser
Create inner classes symbols	Creates a symbol in the diagram for each inner class
Mark classifiers not to be generated	Reversed classifiers (classes and interfaces) will not be generated from the model. To generate the classifier, you must select the Generate check box in its property sheet
Create Associations	Creates associations between classes and/or interfaces

Option	Result of selection
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>

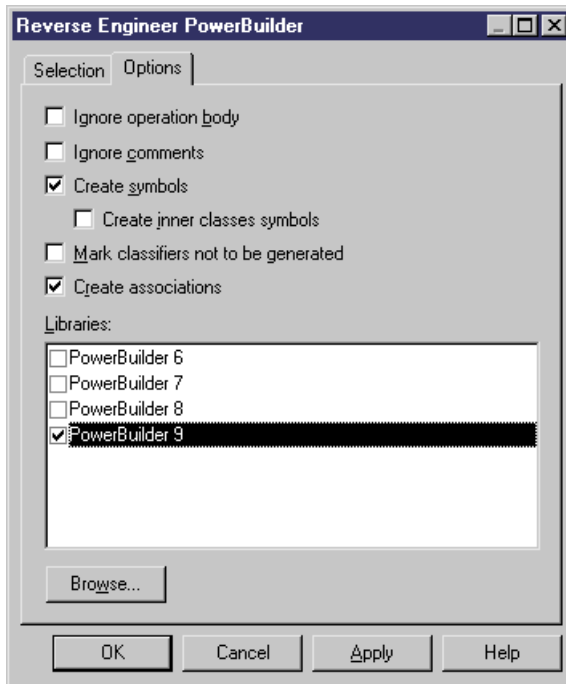

Reverse Engineering System Libraries

Some standard objects like windows or structures, inherit from parent classes defined in the system libraries. If these libraries are not loaded in the workspace, PowerDesigner no longer creates an unresolved class to represent the standard object parent in the model. The link between standard object and parent will be recreated after generation thanks to the standard object stereotype.

Defining PowerBuilder reverse engineering options

To Define PowerBuilder Reverse Engineering Options:

1. Select **Language > Reverse Engineer PowerBuilder** to display the Reverse Engineer PowerBuilder dialog box.
2. Click the Options tab to display the Options tab.

3. Select or clear options.
4. Click Apply and Cancel.

PowerBuilder Reverse Engineering Process

When you reverse engineer objects from PowerBuilder, you can select to reverse engineer libraries, files or directories.

Reverse Engineering Libraries

This mode allows you to select a PowerBuilder target/application from the Target/Application list. When a target or an application is selected, the libraries used by the target or application are automatically displayed in the list. By default all objects of all libraries are selected. You can deselect objects and libraries before starting reverse engineering.

If PowerBuilder is not installed on your machine, the Target/Application list remains empty.

Reverse Engineering Source Files

This mode allows you to select PowerBuilder object source files to reverse engineer. The extension of the source file determines the type of the reversed object.

You can right-click the files to reverse engineer and select the Edit command to view the content of your files. To use this command you have to associate the file extension with an editor in the General Options\Editor dialog box.

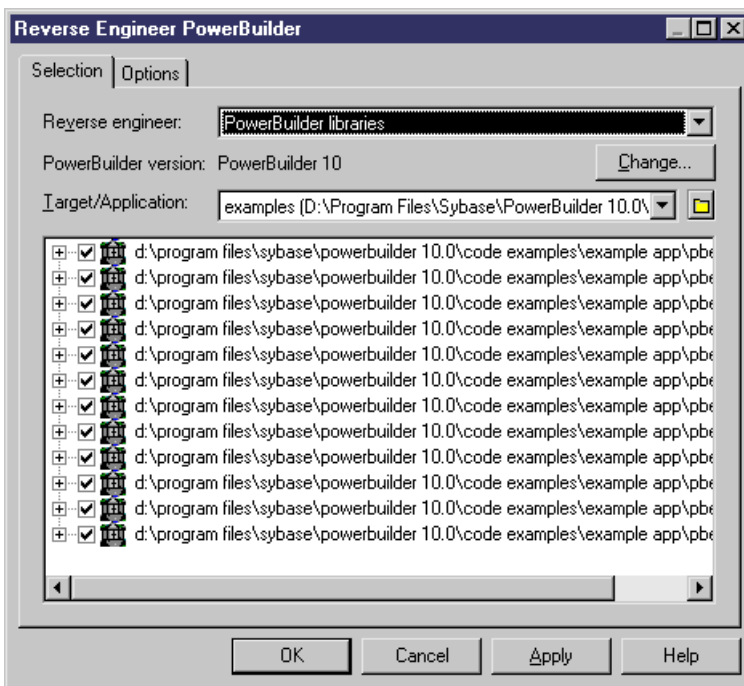

Reverse Engineering Directories

This mode allows you to select a PowerBuilder directory to reverse engineer. When you select a directory, you cannot select individual target or application. Use the Change button to select a directory.

Reverse Engineering PowerBuilder Objects

To reverse engineer PowerBuilder objects:

1. Select **Language > Reverse Engineer PowerBuilder** to display the Reverse Engineer PowerBuilder dialog box.
2. Select a file, library or directory in the Reverse Engineering box.
3. When available, select a target or application in the list.

4. Click OK.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The classes are added to your model. They are visible in the diagram and in the Browser. They are also listed in the Reverse tab of the Output window, located in the lower part of the main window.

Loading a PowerBuilder Library Model in the Workspace

When you reverse engineer PowerBuilder files, you can, at the same time, load one of the PowerBuilder models that contains the class libraries of a particular version of PowerBuilder. The Setup program installs these models in the Library directory.

You can select to reverse a PowerBuilder library model from the Options tab of the Reverse Engineer PowerBuilder dialog box.

You can open a PowerBuilder library model in the workspace from the Library directory.

1. Select **File > Open** to display the Open dialog box.
2. Select or browse to the Library directory.

The available library files are listed. Each PB file corresponds to a particular version of PowerBuilder.

3. Select the file corresponding to the version you need.

This file contains all the library class files of the PowerBuilder version that you have chosen.

4. Click Open.

The OOM opens in the workspace.

CHAPTER 17 Working with VB .NET

PowerDesigner supports the modeling of VB .NET programs including round-trip engineering.

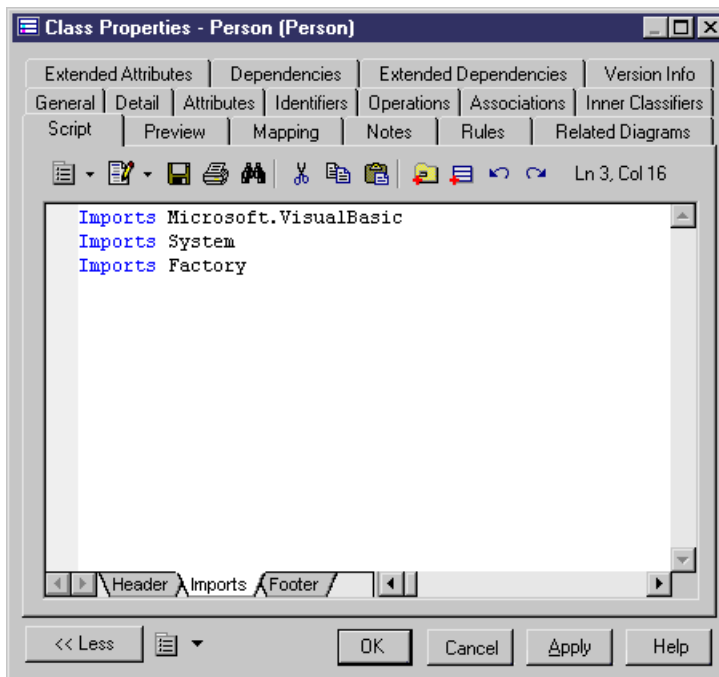

What Is Automatically Generated

During VB .NET generation, each top object, that is to say class, interface, module, and so on, generates a source file with the .vb extension. Inner classifiers are generated in the source of the container classifier.

Imports

The *Imports* directive can appear at the beginning of the script of each generated file.

You can define imports in PowerDesigner in the Script\Imports sub-tab of the property sheet of a main object. You can type the import statement or use the Import Folder or Import Classifier tools in the Imports sub-tab.

Options

Options appear in the generated file header. You can define the following options for main objects:

- *Compare*: type the value Text or Binary in the value box of the Compare extended attribute of the generated top object
- *Explicit*: select True or False in the value box of the Explicit extended attribute of the generated top object
- *Strict*: select True or False in the in the value box of the Strict extended attribute of the generated top object

Supported VB .NET Objects

This section develops the VB .NET concepts supported in PowerDesigner.

Inheritance & Implementation

You design VB .NET *inheritance* using a *generalization* link between classes.

You design VB .NET *implementation* using a *realization* link between a class and an interface.

Namespace

You define a VB .NET *namespace* using a package.

Only packages with the Use Parent Namespace check box deselected become VB .NET namespaces.

In the following example, class Architect is declared in package Design which is a sub-package of Factory. The namespace declaration is the following:

```
Namespace Factory.Design
  Public Class Architect
  ...
  ...End Class
End Namespace ' Factory.Design
```

Classifiers defined directly at the model level fall into the VB .NET global namespace.

Project

You can reverse engineer VB .NET projects when you select VB .NET projects from the Reverse Engineer list in the Reverse Engineer VB .NET dialog box.

Make sure you reverse engineer each project into a separate model.

Assembly properties are reverse engineered as follow:

VB .NET assembly properties	PowerDesigner equivalent
Title	Name of the model
Description	Description of the model
Company	AssemblyCompany extended attribute
Copyright	AssemblyCopyright extended attribute
Product	AssemblyProduct extended attribute
Trademark	AssemblyTrademark extended attribute
Version	AssemblyVersion extended attribute
AssemblyInformationalVersion AssemblyFileVersion AssemblyDefaultAlias	Stored in CustomAttributes extended attribute

Project properties are reverse engineered as extended attributes whether they have a value or not. For example, the default HTML page layout is saved in extended attribute DefaultHTMLPageLayout.

You can use the Ellipsis button in the Value column to modify the extended attribute value, however you should be very cautious when performing such changes as they may jeopardize model generation.

Accessibility

To define *accessibility* for a class, an interface, an attribute or a method, you have to use the *visibility* property in PowerDesigner. The following accessibility attributes are supported in PowerDesigner:

VB .NET accessibility	PowerDesigner visibility
<i>Public</i> (no restriction)	<i>Public</i>
<i>Protected</i> (accessible by derived classes)	<i>Protected</i>
<i>Friend</i> (accessible within the program that contains the declaration of the class)	<i>Friend</i>
<i>Protected Friend</i> (accessible by derived classes and within the program that contains the declaration of the class)	<i>Protected Friend</i>
<i>Private</i> (only accessible by the class)	<i>Private</i>

In the following example, the visibility of class Customer is friend:

```
Friend Class Customer
```

Class

You design a VB .NET *class* using a class in PowerDesigner. VB .NET classes can contain events, variables, constants, methods, constructors and properties.

The following specific classes are also supported in PowerDesigner:

- *MustInherit* class is equivalent to an abstract class. To design this type of class you need to create a class and select the *Abstract* check box in the General tab of the class property sheet.

```
Public MustInherit Class Customer
Private Name As Char
Private ID As Integer
End Class
```

- *NotInheritable* class is equivalent to a final class. To design this type of class, you need to create a class and select the *Final* check box in the General tab of the class property sheet.

```
Public NotInheritable Class FinalClass
Private At1 As Object
Private At2 As Object
End Class
```

Structure

You design a VB .NET *structure* using a class with the <<structure>> stereotype. Structures can implement interfaces but do not support inheritance; they can contain events, variables, constants, methods, constructors, and properties.

The following structure contains two attributes and a constructor operation:

```
...
Public Class Point
Protected Y As Integer
Protected X As Integer
Public Sub New()

End Sub
```

```
End Class
...
```

Interface

You design a VB .NET *interface* using an interface in PowerDesigner. VB .NET interfaces can contain events, properties, and methods; they do not support variables, constants, and constructors.

Nested Types

You design a VB .NET *nested type* using an inner class or interface.

Module

You design a VB .NET *module* using a class with the <<Module>> stereotype and attributes, functions, subs and events.

In the following example, you define a module Test using a class with the <<Module>> stereotype. Test contains a *function*. To design this function you have to create an operation called Main and empty the return type property. You can then define the function body in the implementation tab of this operation.

```
...
Public Module Test
  Public Sub Main()
    Dim val1 As Integer = 0
    Dim val1 As Integer = val1
    val2 = 123
    Dim ref1 As New Class1 ()
    Dim ref1 As Class1 = ref1
    ref2.Value = 123
    Console.WriteLine ("Value: "& val1, "& val2)
    Console.WriteLine ("Refs: "&ref1.Value &, "& ref2.Value)

  End Sub
End Module
...
```

Enumeration

You design a VB .NET *enumeration* using a class with the <<enumeration>> stereotype. The code of the class attributes is used as enumeration values.

- *Data Type*: You set the enumeration data type using the *EnumDataType* extended attribute of the enumeration. You can type for example Byte, Short, or Long in the value column of the extended attribute

- *Initial Expression*: You set the enumeration *Initial Expression* by defining a value in the *Initial Value* box of an enum attribute

<<enumeration>>	
Day	
-	Monday
-	Tuesday
-	Wednesday
-	Thursday
-	Friday
-	Saturday
-	Sunday
-	FirstDay = Monday
-	LastDay = Sunday

```
Public Enum Day
Monday
Tuesday
Wednesday
Thursday
Friday
Saturday
Sunday
FirstDay = Monday
LastDay = Sunday
End Enum
```

Custom Attributes

To define *custom attributes* for a class, an interface, a variable, a parameter or a method, you have to use the *Custom attributes* extended attribute in PowerDesigner. You can use the Custom attributes input box to type all the custom attributes you wish to add using the correct VB .NET syntax.

The screenshot shows a dialog box titled "CustomAttributes". Inside the dialog, there is a text area with the following content:

```
Author('Me', version := 1.1).
HelpString('This field uses custom attributes')
```

 At the bottom of the dialog, there are two buttons: "OK" and "Cancel".

Custom Attributes for Return Types

You can use *the Return type custom attribute* extended attribute to define custom attributes for the return type of a property attribute or a method.

Shadows

Shadows indicates that an inherited element hides a parent element with the same name. To design a *shadows* class or interface, you have to set the class or interface *Shadows* extended attribute to True.

In the following example, class `DialogBox` inherits from class `Window`. Class `Window` contains an inner classifier `Control`, and so does class `DialogBox`. You do not want class `DialogBox` to inherit from the control defined in `Window`, to do so, you have to set the *Shadows* extended attribute to True, in the `Control` class inner to `DialogBox`:

```

...
Public Class DialogBox
  Inherits Window
  Public Shadows Class Control
End Class
End Class
...

```

Variables

You design a VB .NET *variable* using an attribute in PowerDesigner. The following table summarizes the different types of VB .NET variables and attributes supported in PowerDesigner:

VB .NET variable	PowerDesigner equivalent
<i>ReadOnly</i> variable	Attribute with <i>Read-only</i> changeability
<i>Const</i> variable	Attribute with <i>Frozen</i> changeability
<i>Shared</i> variable	Attribute with <i>Static</i> property selected
<i>Shadowing</i> variable	Extended attribute <i>Shadowing</i> set to <i>Shadows</i> or <i>Overloads</i>
<i>WithEvents</i> variable	Attribute with <i>withEvents</i> stereotype

VB .NET variable	PowerDesigner equivalent
<i>Overrides</i> variable	Extended attribute <i>Overrides</i> set to True
<i>New</i> variable	Extended attribute <i>AsNew</i> set to True

- *Data Type*: You define the data type of a variable using the attribute Data Type property
- *Initial Value*: You define the initial value of a variable using the attribute Initial Value property
- *Shadowing*: To define a shadowing by name set the Shadowing extended attribute to Shadows. To define a shadowing by name and signature set the Shadowing extended attribute to Overloads. See *Method* on page 467 for more details on shadowing

Property

To design a VB .NET *property* you have to design an attribute with the <<*Property*>> stereotype, another attribute with the <<*PropertyImplementation*>> stereotype is automatically created, it is displayed with an underscore sign in the list of attributes. The corresponding getter and setter operations are also automatically created.

You can get rid of the implementation attribute.

If you remove the getter operation, the *ReadOnly* keyword is automatically generated. If you remove the setter operation, the *WriteOnly* keyword is automatically generated. If you remove both getter and setter operations, the attribute no longer has the <<*Property*>> stereotype.

When you define a <<*Property*>> attribute, the attribute changeability and the getter/setter operations are tightly related as explained in the following table:

Operations	Property attribute changeability
If you keep both getter and setter operations	Property is Changeable
If you remove the setter operation of a changeable property	Property becomes Read-only
If you remove the getter operation of a changeable property	Property becomes Write-only

On the other hand, if you modify the property changeability, operations will reflect this change, for example, if you turn a changeable property into a read-only property, the setter operation is automatically removed.

In the following example, class Button contains a property Caption. The Getter operation has been removed which causes the *WriteOnly* keyword to appear in the property declaration line:

Button	
-	captionValue : String
+ <<Property>>	WriteOnly Caption : String
+ <<Setter>>	SetCaption (String Value)

```

Public Class Button
    Private captionValue As String
    Public WriteOnly Property Caption() As String
        Set (ByVal Value As String)
            captionValue = value
            Repaint()
        End Set
    End Property
End Class

```

- *Must override*: Set the Must override extended attribute of the property to True to express that the property in a base class must be overridden in a derived class before it can be used
- *Overridable*: Set the Overridable extended attribute of the property to True to express that the property can be overridden in a derived class
- *Overrides*: Set the Overrides extended attribute of the property to True to express that a property overrides a member inherited from a base class
- *Parameters*: Type a value in the value box of the *Property parameters* extended attribute to specify which value of the property attribute is to be used as parameter. In the following example, class Person contains property attribute ChildAge. The parameter used to sort the property is ChildName:

Person	
- <<Property>>	ChildAge : Integer
- <<PropertyImplementation>>	_ChildAge : Integer
+ <<Setter>>	set_ChildAge (Integer newChildAge)
+ <<Getter>>	get_ChildAge ()

```

Public Class Person
    Private _ChildAge As Integer

    Private Property ChildAge(ChildName as String) As Integer
        Get
            return _ChildAge
        End Get
        Set (ByVal Value ChildAge As Integer)
            If (_ChildAge <> newChildAge)
                _ChildAge = newChildAge
            End If
        End Set
    End Property
End Class

```

Method

You design a VB .NET *method* using an operation. Methods can be functions or subs.

You design a *function* using an operation with a return value.

You design a *sub* using an operation with an empty return type.

The following table summarizes the different methods supported in PowerDesigner:

VB .NET method	PowerDesigner equivalent
<i>Shadowing</i> or <i>Overloads</i> method	Select <i>Shadows</i> or <i>Overloads</i> from the <i>Shadowing</i> list on the VB.NET tab of the operation property sheet
<i>Shared</i> method	Select the <i>Static</i> check box on the General tab of the operation property sheet
<i>NotOverridable</i> method	Select the <i>Final</i> check box on the General tab of the operation property sheet
<i>Overridable</i> method	Select the <i>Overridable</i> check box on the VB.NET tab of the operation property sheet
<i>MustOverride</i> method	Select the <i>Abstract</i> check box on the General tab of the operation property sheet
<i>Overrides</i> method	Select the <i>Overrides</i> check box on the VB.NET tab of the operation property sheet

Shadowing

To define a shadowing by name, select *Shadows* from the *Shadowing* list on the VB.NET tab of the operation property sheet . To define a shadowing by name and signature select *Overloads*. In the following example, class Derived inherits from class Base:

Operation F in class Derived overloads operation F in class Base; and operation G in class Derived shadows operation G in class Base:

```

Public Class Derived
  Inherits Base
  Public Overloads Sub F(ByVal i As Integer)
  End Sub
  Public Shadows Sub G(ByVal i As Integer)
  End Sub
End Class
  
```

Method Parameters

You define VB .NET method parameters using operation parameters.

You can define the following parameter modifiers in PowerDesigner:

VB .NET modifier	PowerDesigner equivalent
<i>ByVal</i>	Select <i>In</i> in the Parameter Type box on the parameter property sheet General tab
<i>ByRef</i>	Select <i>In/Out</i> or <i>Out</i> in the Parameter Type box on the parameter property sheet General tab
<i>Optional</i>	Set the <i>Optional</i> extended attribute on the Extended Attributes tab to True
<i>ParamArray</i>	Select the <i>Variable Argument</i> checkbox on the parameter property sheet General tab

Method Implementation

Class methods are implemented by the corresponding interface operations. To define the implementation of the methods of a class, you have to use the To be implemented button in the Operations tab of a class property sheet, then click the Implement button for each method to implement. The method is displayed with the `<<Implement>>` stereotype.

Constructor & Destructor

You design VB .NET *constructors* and *destructors* by clicking the *AddDefault Constructor/Destructor* button in the list of operations of a class. This automatically creates a constructor called New with the Constructor stereotype, and a destructor called Finalize with the Destructor stereotype. Both constructor and destructor are grayed out in the list, which means you cannot modify their definition, but you can still remove them from the list.

Delegate

You can design the following types of VB .NET *delegates*:

- To create a delegate at the namespace level, create a class with the `<<Delegate>>` stereotype, and add an operation with the `<<Delegate>>` stereotype to this class and define a visibility for this operation. This visibility becomes the visibility of the delegate

```

...
Public Delegate Function ActionOccurred () As Object
...
  
```

- To create a delegate in a class, module, or structure, you just have to create an operation with the `<<Delegate>>` stereotype. In the following example, class Worker is inner to module Utilities. Both contain internal delegates designed as operations with the `<<Delegate>>` stereotype

```

...
Public Module Utilities
  Public Delegate Function NewWorker () As Object
  Public Class Worker
    Public Delegate Function WorkStarted () As Object
  End Class
End Module
...

```

Event

To define an event in VB .NET you must declare its signature. You can either use a delegate as a type for this event or define the signature on the event itself. Both declarations can be mixed in a class.

The delegate used as a type is represented by an attribute with the <<Event>> stereotype. You define the delegate name using the attribute data type.

```

Public Class Printer
  Public PaperJam As EventHandler
  Public OutOfPaper As EventHandler
  Public JobOK As PrinterGoodDelegate
End Class

```

When you define the signature on the event itself, you have to use an operation with the <<Event>> stereotype. The signature of this operation then becomes the signature of the event.

```

Public Class Printer
  Public Event PaperJam(ByVal p As Printer, ByVal e As EventArgs)
  Public Event JobOK(ByVal p As Object)
End Class

```

Event Implementation

To design the implementation clause of a delegate used as a type you have to type a clause in the *implements* extended attribute of the <<Event>> attribute.

For <<Event>> operations, you have to use the To Be Implemented feature in the list of operations of the class.

Event Handler

To define a VB .NET *event handler* you should already have an operation with the <<event>> stereotype in your class. You then have to create another operation, and type the name of the <<event>> operation in the *Handles* extended attribute Value box.

Printer	
+ <<event>>	Print() : Object
+	Operation_2() : Object

```
...
Public Function Operation_2() As Object Handles Print
    End Function
...
```

External Method

You define a VB .NET external method using an operation with the <<External>> stereotype. External methods share the same properties as standard methods.

You can also define the following specific properties for an external method:

- *Alias clause*: you can use the *Alias name* extended attribute to specify numeric ordinal (prefixed by a @ character) or a name for an external method
- *Library clause*: you can use the *Library name* extended attribute to specify the name of the external file that implements the external method
- *ANSI*, *Unicode* and *Automodifiers* used for calling the external method can be defined using the *Character set* extended attribute of the external method

Generating for VB.NET

This section explains some of the features of the VB.NET object language in order to generate VB code from objects in the OOM.

Defining VB .NET Environment Variables

Variables used for VB .NET generation are defined in the General Options dialog box.

For more information on variables and general options, see "Customizing your Modeling Environment" section in the Models chapter of the *Core Features Guide*.

The following variables can be defined in the General Options dialog box:

Variable	Description
VBC	VB .NET compiler full path. For example, C:\WINDOWS\Microsoft.NET\Framework\v1.0.3705\vbc.exe
WSDL	Web Service proxy generator full path. For example, C:\Program Files\Microsoft Visual Studio .NET\FrameworkSDK\Bin\wsdl.exe

Selecting VB .NET Generation Options

You can set the following option, available from the Options tab of the Generation dialog box in VB .NET:

Options	Description
Generate VB .NET Web Service code in .ASM file instead of .VB file	Generates the Visual Basic code in the .ASM file
Generate Visual Studio .NET project files	Generates the files of the Visual Studio .NET project. A solution file is generated together with several project files, each project corresponding to a model or a package with the <<Assembly>> stereotype
Generate object ids as documentation tags	Generates information used for reverse engineering like object identifiers (@pdoid) that are generated as documentation tags. If you do not want these tags to be generated, you have to set this option to False
Visual Studio .NET version	Indicates the version number of Visual Studio .NET

Selecting VB .NET Generation Tasks

The Tasks category contains the following commands:

Options	Description
Generate Web service proxy code (WSDL)	Generates the proxy class
Compile Visual Basic .NET source files	Compiles the source files
Open the solution in Visual Studio .NET	If you selected the Generate Visual Studio .NET project files option, this task allows to open the solution in the Visual Studio .NET development environment

Generating VB.NET Files

The files generated are generated with the .vb extension. A generation log file is also created after generation.

1. Select **Language > Generate VB.NET Code** to display the Generation dialog box.
2. Type a destination directory for the generated file in the Directory box.

or

Click the Select a Path button to the right of the Directory box and browse to select a directory path.

3. Click the Selection tab, then select the objects to include in the generation from the sub-tabs at the bottom of the tab.

Note: All classes of the model, including those grouped into packages, are selected and displayed by default. You use the Select tools to the right of the Folder Selection list to modify the selection. The Include Sub-Packages tool allows you to include all classes located within packages.

4. Click the Options tab to display the Options tab.
5. <optional> Select the Check Model check box if you want to verify the validity of your model before generation.
6. Select a value for each required option.
7. Click the Tasks, then select the required task(s).
8. Click OK to generate.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation tab of the Output window, located in the bottom part of the main window.

All VB files are generated in the destination directory.

Reverse Engineering VB .NET

You can reverse engineer VB .NET files into an OOM.

In the Selection tab, you can select to reverse engineer files, directories or projects.

You can also define a base directory. The base directory is the common root directory for all the files to reverse engineer. This base directory will be used during regeneration to recreate the exact file structure of the reverse engineered files.

Edit Source

You can right-click the files to reverse engineer and select the Edit command to view the content of your files. To use this command you have to associate the file extension with an editor in the General Options\Editor dialog box.

Selecting VB .NET Reverse Engineering Options

You define the following VB .NET reverse engineering option from the Reverse Engineer VB .NET dialog box:

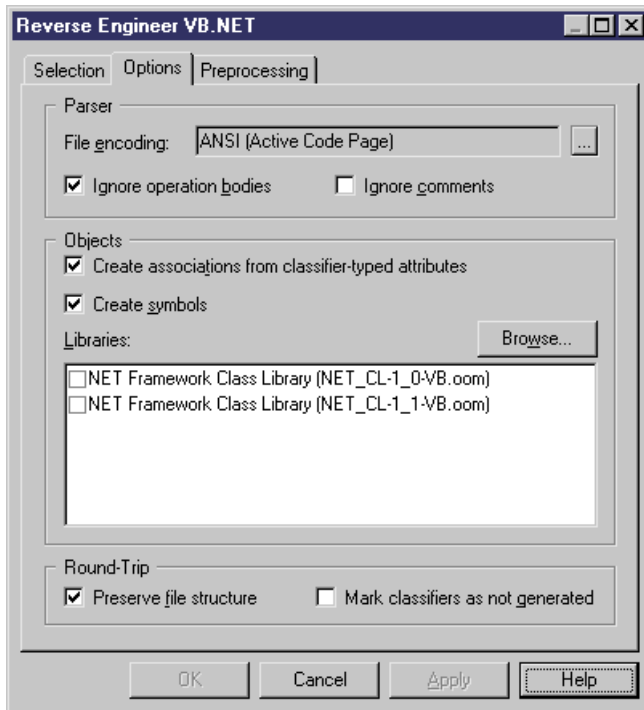

Option	Result of selection
File encoding	Allows you to modify the default file encoding of the files to reverse engineer
Ignore operation body	Reverses classes without including the body of the code
Ignore comments	Reverses classes without including code comments
Create Associations from classifier-typed attributes	Creates associations between classes and/or interfaces
Create symbols	Creates a symbol for each object in the diagram, if not, reversed objects are only visible in the browser
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>
Preserve file structure	Creates an artifact during reverse engineering in order to be able to regenerate an identical file structure

Option	Result of selection
Mark classifiers not to be generated	Reversed classifiers (classes and interfaces) will not be generated from the model. To generate the classifier, you must select the Generate check box in its property sheet

Defining VB .NET Reverse Engineering Options

To define VB .NET reverse engineering options:

1. Select **Language > Reverse Engineer VB .NET**.
2. Click the Options tab to display the Options tab.

3. Select or clear reverse engineering options.
4. Browse to the Library directory, if required.
5. Click Apply and Cancel.

VB .NET Reverse Engineering Preprocessing

VB .NET files may contain conditional code that needs to be handled by *preprocessing directives* during reverse engineering. A preprocessing directive is a command placed within the source code that directs the compiler to do a certain thing before the rest of the source code is parsed and compiled. The preprocessing directive has the following structure:

```
#directive symbol
```

Where *#* is followed by the name of the directive, and *symbol* is a conditional compiler constant used to select particular sections of code and exclude other sections.

In VB .NET symbols have values.

In the following example, the *#if* directive is used with symbols *FrenchVersion* and *GermanVersion* to output French or German language versions of the same application from the same source code:

```
#if FrenchVersion Then
' <code specific to French language version>.
#elseif GermanVersion Then
' <code specific to French language version>.
#else
' <code specific to other language version>.
#end if
```

You can declare a list of symbols for preprocessing directives. These symbols are parsed by preprocessing directives: if the directive condition is true the statement is kept, otherwise the statement is removed.

VB .NET Supported Preprocessing Directives

The following directives are supported during preprocessing:

Directive	Description
#Const	Defines a symbol
#If	Evaluates a condition, if the condition is true, the statement following the condition is kept otherwise it is ignored
#Else	If the previous #If test fails, source code following the #Else directive will be included
#Else If	Used with the #if directive, if the previous #If test fails, #Else If includes or exclude source code, depending on the resulting value of its own expression or identifier
#End If	Closes the #If conditional block of code

Note: #Region, #End Region, and #ExternalSource directives are removed from source code.

Defining a VB .NET Preprocessing Symbol

You can define VB .NET preprocessing symbols and values in the preprocessing tab of the reverse engineering dialog box.

Symbol names are not case sensitive but they must be unique. Make sure you do not type reserved words like true, false, if, do and so on. You must always assign a value to a symbol, this value can be a string (no " " required), a numeric value, a boolean value or Nothing.

The list of symbols is saved in the model and will be reused when you synchronize your model with existing code using the Synchronize with Generated Files command.

For more information on the Synchronize with Generated Files command see *Synchronizing a Model with Generated Files* on page 282.

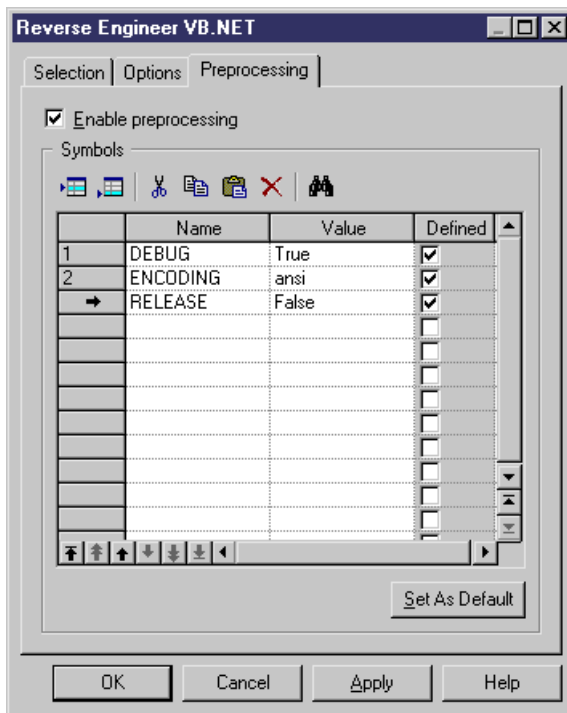

You can use the Set As Default button to save the list of symbols in the registry.

1. Select **Language > Reverse engineering VB .NET**.

The Reverse Engineering VB .NET dialog box is displayed.

2. Click the Preprocessing tab, then click the Add a row tool to insert a line in the list.
3. Type symbol names in the Name column.
4. Type symbol value in the Value column.

The Defined check box is automatically selected for each symbol to indicate that the symbol will be taken into account during preprocessing.

5. Click Apply.

VB .NET Reverse Engineering with Preprocessing

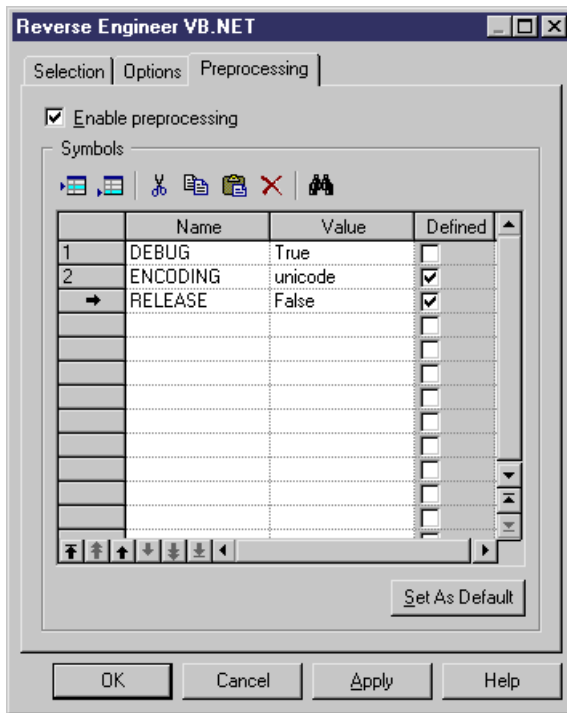

Preprocessing is a reverse engineering option you can enable or disable.

1. Select **Language > Reverse engineering VB .NET**.

The Reverse Engineering VB .NET dialog box is displayed.

2. Select files to reverse engineer in the Selection tab.

3. Select reverse engineering options in the Options tab.
4. Select the Enable preprocessing check box in the Preprocessing tab.
5. Select symbols in the list of symbols.

6. Click OK to start reverse engineering.

When preprocessing is over the code is passed to reverse engineering.

Reverse Engineering VB .NET Files

You can reverse engineer VB .NET files.

1. Select **Language > Reverse Engineer VB .NET** to display the Reverse Engineer VB .NET dialog box.
2. Select to reverse engineer files or directories from the Reverse Engineering list.
3. Click the Add button in the Selection tab.

A standard Open dialog box is displayed.

4. Select the items or directory you want to reverse engineer.

Note: You select several files simultaneously using the ctrl or shift keys. You cannot select several directories.

The Reverse VB .NET dialog box displays the files you selected.

5. Click OK.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The classes are added to your model. They are visible in the diagram and in the Browser. They are also listed in the Reverse tab of the Output window, located in the lower part of the main window.

Working with ASP.NET

An Active Server Page (ASP) is an HTML page that includes one or more scripts (small embedded programs) that are interpreted by a script interpreter (such as VBScript or JScript) and that are processed on a Microsoft Web server before the page is sent to the user. An ASP involves programs that run on a server, usually tailoring a page for the user. The script in the Web page at the server uses input received as the result of the user's request for the page to access data from a database and then builds or customizes the page on the fly before sending it to the requestor.

ASP.NET (also called ASP+) is the next generation of Microsoft Active Server Page (ASP). Both ASP and ASP.NET allow a Web site builder to dynamically build Web pages on the fly by inserting queries to a relational database in the Web page. ASP.NET is different than its predecessor in two major ways:

- It supports code written in compiled languages such as Visual Basic, VB .NET, and Perl
- It features server controls that can separate the code from the content, allowing WYSIWYG editing of pages

ASP.NET files have a .ASPX extension. In an OOM, an ASP.NET is represented as a file object and is linked to a component (of type ASP.NET). The component type Active Server Page (ASP.NET) allows you to identify this component. Components of this type are linked to a single file object that defines the page.

When you set the type of the component to ASP.NET, the appropriate ASP.NET file object is automatically created, or attached if it already exists. You can see the ASP.NET file object from the Files tab in the component property sheet.

ASP Tab of the Component

When you set the type of the component to ASP.NET, the ASP tab is automatically displayed in the component property sheet.

The ASP tab includes the following properties:

Property	Description
ASP file	File object that defines the page. You can click the Properties tool beside this box to display the property sheet of the file object, or click the Create tool to create a file object
Default template	Extended attribute that allows you to select a template for generation. Its content can be user defined or delivered by default

To modify the default content, edit the current object language from **Language > Edit Current Object Language** and modify the following item: Profile/FileObject/Criteria/ASP/Templates/DefaultContent<%is(DefaultTemplate)%>. Then create the templates and rename them as DefaultContent<%is(<name>)%> where <name> stands for the corresponding DefaultContent template name.

To define additional DefaultContent templates for ASP.NET, you have to modify the ASPTemplate extended attribute type from Profile/Share/Extended Attribute Types and add new values corresponding to the new templates respective names.

For more information on the default template property, see the definition of TemplateContent in *Creating an ASP.NET with the wizard* on page 480.

Defining File Objects for ASP.NET

The file object content for ASP is based on a special template called DefaultContent defined with respect to the FileObject metaclass. It is located in the Profile/FileObject/Criteria/ASP/Templates category of the C# and VB.NET object languages. This link to the template exists as a basis, therefore if you edit the file object, the link to the template is lost - the mechanism is similar to that of operation default bodies.

For more information on the Criteria category, see "Criteria (Profile)", in the Extending your Models with Profiles chapter of the *Customizing and Extending PowerDesigner* manual.

Active Server Page files are identified using the ASPFile stereotype. The server page name is synchronized with the ASP.NET component name following the convention specified in the Value box of the Settings/Namings/ASPFileName entry of the C# and VB.NET object languages.

You can right-click a file object, and select Open With text editor from the contextual menu to display the content of the file object.

Creating an ASP.NET with the Wizard

You can create an ASP.NET with the *wizard* that will guide you through the creation of the component. The wizard is invoked from a class diagram. It is only available if the language is C# or VB.NET.

You can either create an ASP.NET without selecting any file object, or select a file object beforehand and start the wizard from the Tools menu.

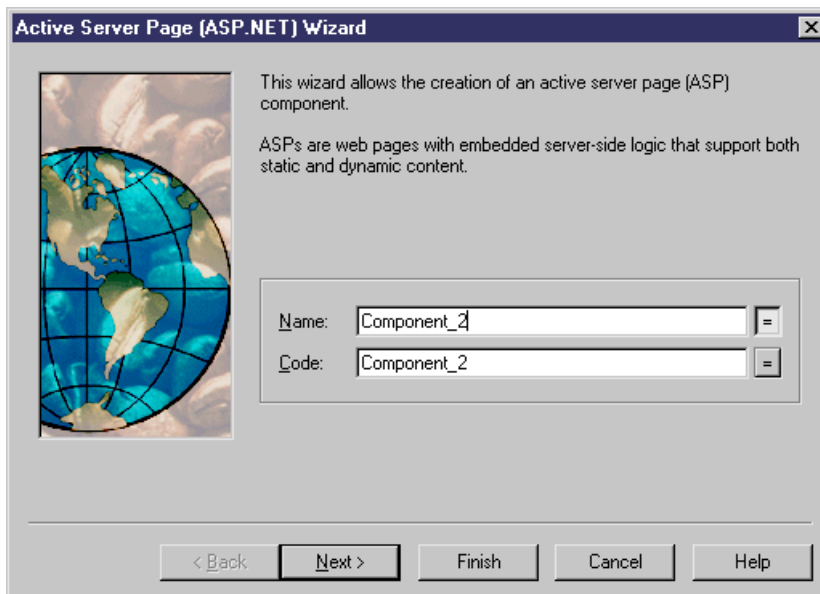

You can also create several ASP.NET of the same type by selecting several file objects at the same time. The wizard will automatically create one ASP.NET per file object: the file objects you have selected in the class diagram become ASP.NET files.

The wizard for creation of an ASP.NET lets you define the following parameters:

Wizard page	Description
Name	Name of the ASP.NET component
Code	Code of the ASP.NET component
TemplateContent	Allows you to choose the default template of the ASP.NET file object. The TemplateContent is an extended attribute located in the Profile/Component/Criteria/ASP category of the C# and VB.NET object languages. If you do not modify the content of the file object, the default content remains (see the Contents tab of the file object property sheet). All templates are available in the FileObject/Criteria/ASP/templates category of the current object language
Create symbol	Creates a component symbol in the diagram specified beside the Create symbol In check box. If a component diagram already exists, you can select one from the list. You can also display the diagram properties by selecting the Properties tool

1. Select **Tools > Create ASP** from a class diagram.

The Active Server Page Wizard dialog box is displayed.

2. Select a name and code for the ASP.NET component and click Next.
3. Select an ASP.NET template and click Next.
4. At the end of the wizard, you have to define the creation of symbols.

When you have finished using the wizard, the following actions are executed:

- An ASP.NET component and a file object with an extension .ASPX are created and visible in the Browser. The file object is named after the original default component name to preserve coherence
- If you open the property sheet of the file object, you can see that the Artifact property is selected

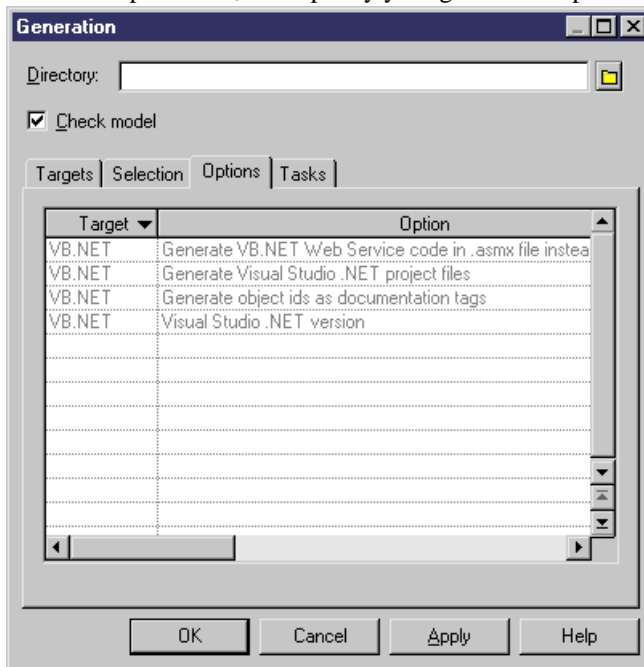

For more information on artifact file objects, see *File Object Properties* on page 228.

- You can edit the file object directly in the internal editor of PowerDesigner, if its extension corresponds to an extension defined in the Editors page of the General Options dialog box, and if the <internal> keyword is defined in the Editor Name and Editor Command columns for this extension

Generating ASP.NET

The generation process generates only file objects having the Artifact property selected.

1. Select **Language > Generate C# or VB.NET code** to display the Generation dialog box.
2. Select or browse to a directory that will contain the generated files.
3. Click the Selection tab, then select the objects you need in the different sub-tabs.
4. Click Apply.
5. Click the Options tab, then specify your generation options in the Options tab.

For more information on the generation options, see *Selecting VB .NET Generation Options* on page 472.

6. Click Apply.
7. Click the Tasks tab to display the Tasks tab.
8. Select the commands you want to perform during generation in the Tasks tab.

For more information on the generation tasks, see *Selecting VB .NET Generation Tasks* on page 472.

You must beforehand set the environment variables from General Options dialog box (Variables section) in order to activate them in this tab.

For more information on how to set these variables, see "Defining environment variables" section in the Models chapter of the *Core Features Guide*.

9. Click OK.

A progress box is displayed, followed by a Result list. You can use the Edit button in the Result list to edit the generated files individually.

10. Click Close.

The files are generated in the generation directory.

CHAPTER 18 Working with Visual Basic 2005

PowerDesigner provides full support for modeling all aspects of Visual Basic 2005 including round-trip engineering.

Visual Basic 2005 is a high-level programming language for the Microsoft .NET framework.

PowerDesigner can be used as a standalone product and as a plug-in for the Visual Studio 2005 development environment, allowing you to integrate its enterprise-level modeling capabilities in your standard .NET workflow. For more information, see the *Working with the VS2005 Plug-in* manual.

This chapter outlines the specifics of PowerDesigner's support for modeling the Visual Basic 2005 language, and should be read in conjunction with the language-neutral chapters in Part One of this book.

Custom Visual Basic 2005 Tools

In addition to PowerDesigner's standard palettes, the following custom tools are available to help you rapidly develop your class and composite structure diagrams:

Icon	Tool
	Assembly – a collection of Visual Basic 2005 files (see <i>Visual Basic 2005 Assemblies</i> on page 485).
	Custom Attribute – for adding metadata (see <i>Visual Basic 2005 Custom Attributes</i> on page 502).
	Delegate – type-safe reference classes (see <i>Visual Basic 2005 Delegates</i> on page 494).
	Enum – sets of named constants (see <i>Visual Basic 2005 Enums</i> on page 496).
	Struct – lightweight types (see <i>Visual Basic 2005 Structs</i> on page 493).

Visual Basic 2005 Assemblies

An assembly is a collection of Visual Basic 2005 files that forms a DLL or executable. PowerDesigner provides support for both:

- single-assembly models, where the model represents the assembly, and

- multi-assembly models, where each assembly appears directly below the model in the Browser tree, and is modeled as a standard UML package with a stereotype of <<Assembly>>.

Creating an Assembly

PowerDesigner supports both single-assembly and multi-assembly models. By default, when you create a Visual Basic 2005 OOM, the model itself represents an assembly.

To Continue with a Single-assembly Model:

In the top-level diagram, insert a type or a namespace. The model will default to a single-module assembly, with the model root representing the assembly.

To Work with a Multi-assembly Model:

In the top-level diagram, insert an assembly in any of the following ways:

- Use the Assembly tool in the Visual Basic 2005 diagram Palette.
- Select **Model > Assembly Objects** to access the List of Assembly Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Assembly**.

Note that, if these options are not available to you, then you are currently working with a single-assembly model. See *Converting a single-assembly model to a multi-assembly model* on page 486.

The model will default to a multimodule assembly, with each assembly represented by a standard UML package symbol, and appearing directly below the model in the Browser tree.

Converting a Single-assembly Model to a Multi-assembly Model

You may find that you begin by designing a single-module assembly and then need to convert your design to accommodate a multi-module assembly.

1. Right-click the Browser entry for the single-assembly model and select Convert to Multi-Assembly Model from the contextual menu.
2. The Create an Assembly dialog box will open, inviting you to enter a name for the assembly that will contain all the types in your model. Enter a name and then click OK.

PowerDesigner converts the single-assembly model into a multi-assembly model by inserting a new assembly directly beneath the model root to contain all the types present in the model. You can add new assemblies as necessary but only as direct children of the model root.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Assembly Properties

Assembly property sheets contains all the standard package tabs along with the Visual Basic 2005-specific tabs listed in the sections below.

Assembly Property Sheet Application Tab

The Application tab contains the following properties:

Property	Description
Generate Project File	Specifies whether to generate a Visual Studio 2005 project file for the assembly.
Project Filename	Specifies the name of the project in Visual Studio. The default is the value of the assembly code property.
Assembly Name	Specifies the name of the assembly in Visual Studio. The default is the value of the assembly code property.
Root Namespace	Specifies the name of the root namespace in Visual Studio. The default is the value of the assembly code property.
Output Type	Specifies the type of application being designed. You can choose between: <ul style="list-style-type: none"> • Class library • Windows Application • Console Application
Project GUID	Specifies a unique GUID for the project. This field will be completed automatically at generation time.

Assembly Property Sheet Assembly Tab

The Assembly tab contains the following properties:

Property	Description
Generate Assembly Info	Specifies whether to generate an assembly manifest file.
Title	Specifies a title for the assembly manifest. This field is linked to the Name field on the General tab.
Description	Specifies an optional description for the assembly manifest.
Company	Specifies a company name for the assembly manifest.
Product	Specifies a product name for the assembly manifest.
Copyright	Specifies a copyright notice for the assembly manifest.
Trademark	Specifies a trademark for the assembly manifest.

Property	Description
Culture	Specifies which culture the assembly supports.
Version	Specifies the version of the assembly.
File Version	Specifies a version number that instructs the compiler to use a specific version for the Win32 file version resource.
GUID	Specifies a unique GUID that identifies the assembly.
COM Visible	Specifies whether types within the assembly will be accessible to COM.

Visual Basic 2005 Compilation Units

By default, PowerDesigner generates one source file for each class, interface, delegate, or other type, and bases the source directory structure on the namespaces defined in the model.

You may want instead to group multiple classifiers in a single source file and/or construct a directory structure independent of your namespaces.

A compilation-unit allows you to group multiple types in a single source file. It consists of zero or more using-directives followed by zero or more global-attributes followed by zero or more namespace-member-declarations. PowerDesigner models Visual Basic 2005 compilation units as artifacts with a stereotype of <<Source>> and allows you to construct a hierarchy of source directories using folders.

Creating a Compilation Unit

You can create compilation units from the Browser or from the property sheets of types. Compilation units do not have diagram symbols, and are only visible inside the Artifacts folder in the Browser.

Creating an Empty Compilation Unit from the Browser

To create an empty compilation unit from the Browser:

1. Right-click the model or an artifact folder (see *Creating a generation folder structure* on page 490) in the Browser, and select **New > Source** from the contextual menu. The property sheet of the new compilation unit opens.
2. Specify a name for the compilation unit, being sure to retain the .vb extension, and then click OK. The compilation unit is listed in the Browser inside the Artifacts folder. For information on populating it, see *Adding types to compilation units* on page 489.

Creating and Populating a Compilation Unit from the Property Sheet of a Type

To create and populate a compilation unit from the property sheet of a type:

Open the type's property sheet and click the Generated Files tab. If the type is not currently associated with a compilation unit, then the tab will resemble the following:

3. Specify objects to add to the compilation unit by selecting their checkboxes. Note that almost any model object (including other compilation units) can be added to a compilation unit.
4. Click OK to return to the compilation unit property sheet. The selected objects are now listed on the Objects tab.
5. Click OK to close the compilation unit property sheet. The selected objects are now listed beneath the compilation unit in the Browser.

You can also create a compilation unit from the property sheet of a type:

Adding a Type to a Compilation Unit from the Type Property Sheet

To add a type to a compilation unit from the type property sheet:

1. Double-click the type's diagram symbol or browser entry to open its property sheet, and then click the Generated Files tab.
2. In the Artifact(s) column, click the Add/Remove tool to open a selection window listing all the compilation unit available in the model.
3. Specify the compilation units to which the type will be added by selecting their checkboxes. Note that types can be added to multiple compilation units. In this case, they will be generated as partial types (see *Partial Types* on page 492) and you can specify in which compilation unit each of their attributes and methods will be generated.
4. Click OK to return to the type property sheet. The selected compilation units are now listed on the Generated Files tab.
5. Click OK to close the type property sheet. The type is now listed in the Browser, beneath the selected compilation unit(s).

Creating a Generation Folder Structure

You can control the directory structure in which your compilation units will be generated by using artifact folders.

1. Right-click the model or an existing folder within the Artifacts folder in the Browser, and select **New > Artifact Folder** from the contextual menu. The property sheet of the new folder opens.
2. Specify a name for the folder, and then click OK. The new folder is listed in the Browser.

Adding Compilation Units to Folders

To add a compilation unit to a folder, simply drag its browser entry and drop it onto the folder browser entry. Note that folders can contain only compilation units and/or other folders. Thus, to place a type in the generation folder hierarchy, you must first add it to a compilation unit.

Alternatively, you can create a new compilation unit directly in a folder by right-clicking its browser entry, and selecting **New > Source** from the contextual menu.

Previewing the Code to Be Generated for a Compilation Unit

You can preview the code that will be generated for your compilation unit at any time, by opening its property sheet and clicking the Preview tab.

Visual Basic 2005 Namespaces

Namespaces restrict the scope of an object's name. Each class or other type must have a unique name within the namespace.

PowerDesigner models namespaces as standard packages with the Use Parent Namespace property set to false. For information about creating and working with packages, see *Packages (OOM)* on page 48.

In the following example, class Architect is declared in package Design which is a sub-package of Factory. The namespace declaration is the following:

```
Namespace Factory.Design
  Public Class Architect
  ...
  ...End Class
End Namespace ' Factory.Design
```

This structure, part of the NewProduct model, appears in the PowerDesigner Browser as follows:

Classifiers defined directly at the model level fall into the Visual Basic 2005 global namespace.

Visual Basic 2005 Classes

PowerDesigner models Visual Basic 2005 classes as standard UML classes, but with additional properties.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

The following specific classes are also supported in PowerDesigner:

- *MustInherit* class is equivalent to an abstract class. To design this type of class you need to create a class and select the *Abstract* check box in the General tab of the class property sheet.

```
Public MustInherit Class Customer
Private Name As Char
Private ID As Integer
End Class
```

- *NotInheritable* class is equivalent to a final class. To design this type of class, you need to create a class and select the *Final* check box in the General tab of the class property sheet.

```
Public NotInheritable Class FinalClass
Private At1 As Object
Private At2 As Object
End Class
```

Visual Basic 2005 Class Properties

Visual Basic 2005 class property sheets contain all the standard class tabs along with the following properties, located on the VB tab:

Property	Description
Explicit	Specifies the Explicit option directive for the class declaration.
Shadows	Specifies that the class redefines a class defined in a parent class.
Strict	Specifies the Strict option directive for the class declaration.
Compare	Specifies the Compare option directive for the class declaration.

Partial Types

Types may belong to more than one compilation unit.

Partial types are prefixed with the keyword *partial*, as in the following example:

```
public partial class Server
{
private int start;
}
```

In this case, you can specify to which compilation unit each field and method will be assigned by using the Compilation Unit box on the VB tab of their property sheets (see *Field, event, and property properties* on page 498).

For partial types that contain inner types, you can specify the compilation unit to which each inner type will be assigned as follows:

Specifying the Compilation Unit to Which an Inner Type Belongs:

To specify the compilation unit to which an inner type belongs:

1. Open the property sheet of the container type and click the Inner Classifiers tab.
2. Click the Customize Columns and Filter tool, select the CompilationUnit Column Heading from the selection box, and then click OK to return to the tab. The CompilationUnit column is now displayed on the tab.
3. Click in the CompilationUnit column to reveal a list of available compilation units, select one, and click OK to close the property sheet..

Visual Basic 2005 Interfaces

PowerDesigner models Visual Basic 2005 interfaces as standard UML interfaces, with additional properties.

For information about creating and working with interfaces, see *Interfaces (OOM)* on page 52.

Visual Basic 2005 interfaces can contain events, properties, indexers and methods; they do not support variables, constants, and constructors.

Visual Basic 2005 Interface Properties

Visual Basic 2005 interface property sheets contain all the standard interface tabs along with the following properties, located on the VB tab:

Property	Description
Explicit	Specifies the Explicit option directive for the interface declaration.
Shadows	Specifies that the interface redefines a interface defined in a parent interface .
Strict	Specifies the Strict option directive for the interface declaration.
Compare	Specifies the Compare option directive for the interface declaration.

Visual Basic 2005 Structs

Structs are lightweight types that make fewer demands on the operating system and on memory than conventional classes. PowerDesigner models Visual Basic 2005 structs as classes with a stereotype of <<Structure>>.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

A struct can implement interfaces but does not support inheritance; it can contain events, variables, constants, methods, constructors, and properties.

In the following example, the struct contains two attributes and a constructor operation:

Point
Y : Integer
X : Integer
+ <<Constructor>> New()

```
...
Public Class Point
  Protected Y As Integer
  Protected X As Integer
  Public Sub New()

  End Sub
End Class
...
```

Creating a Struct

You can create a struct in any of the following ways:

- Use the Struct tool in the Visual Basic 2005 diagram Palette.
- Select **Model > Struct Objects** to access the List of Struct Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Struct**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Struct Properties

Visual Basic 2005 struct property sheets contain all the standard struct tabs along with the following properties, located on the VB tab:

Property	Description
Explicit	Specifies the Explicit option directive for the struct declaration.
Shadows	Specifies that the struct redefines a struct defined in a parent struct.
Strict	Specifies the Strict option directive for the struct declaration.
Compare	Specifies the Compare option directive for the struct declaration.

Visual Basic 2005 Delegates

Delegates are type-safe reference types that provide similar functions to pointers in other languages. PowerDesigner models delegates as classes with a stereotype of <<Delegate>> with a single operation code-named "<signature>". The visibility, name, comment, flags and attributes are specified on the class object whereas the return-type and parameters are specified on the operation.

You can design the following types of VB .NET *delegates*:

- To create a delegate at the namespace level, create a class with the <<*Delegate*>> stereotype, and add an operation with the <<*Delegate*>> stereotype to this class and define a visibility for this operation. This visibility becomes the visibility of the delegate

```

...
Public Delegate Function ActionOccurred () As Object
...
  
```

- To create a delegate in a class, module, or structure, you just have to create an operation with the <<*Delegate*>> stereotype. In the following example, class Worker is inner to module Utilities. Both contain internal delegates designed as operations with the <<*Delegate*>> stereotype

```

...
Public Module Utilities
    Public Delegate Function NewWorker () As Object
    Public Class Worker
        Public Delegate Function WorkStarted () As Object
    End Class
End Module
...
  
```

For information about creating and working with classes, see *Classes (OOM)* on page 29.

Creating a Delegate

You can create a delegate in any of the following ways:

- Use the Delegate tool in the Visual Basic 2005 diagram Palette.
- Select **Model > Delegate Objects** to access the List of Delegate Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Delegate**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Delegate Properties

Visual Basic 2005 delegate property sheets contain all the standard delegate tabs along with the following properties, located on the VB tab:

Property	Description
Explicit	Specifies the Explicit option directive for the delegate declaration.
Shadows	Specifies that the delegate redefines a delegate defined in a parent delegate.
Strict	Specifies the Strict option directive for the delegate declaration.
Compare	Specifies the Compare option directive for the delegate declaration.

Visual Basic 2005 Enums

Enums are sets of named constants. PowerDesigner models enums as classes with a stereotype of <<Enum>>.

<<enumeration>> Day
- Monday
- Tuesday
- Wednesday
- Thursday
- Friday
- Saturday
- Sunday
- FirstDay = Monday
- LastDay = Sunday

For information about creating and working with classes, see *Classes (OOM)* on page 29.

```
Public Enum Day
Monday
Tuesday
Wednesday
Thursday
Friday
Saturday
Sunday
FirstDay = Monday
LastDay = Sunday
End Enum
```

Creating an Enum

You can create an enum in any of the following ways:

- Use the Enum tool in the Visual Basic 2005 diagram Palette.
- Select **Model > Enum Objects** to access the List of Enum Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Enum**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Enum Properties

Visual Basic 2005 enum property sheets contain all the standard enum tabs along with the following properties, located on the VB tab:

Property	Description
Base Integral Type	Specifies the base integral type for the enum.
Compare	Specifies the Compare option directive for the enum declaration.
Explicit	Specifies the Explicit option directive for the enum declaration.
Shadows	Specifies that the enum redefines a enum defined in a parent enum .
Strict	Specifies the Strict option directive for the enum declaration.

Visual Basic 2005 Fields, Events, and Properties

PowerDesigner models Visual Basic 2005 fields, events, and properties as standard UML attributes with additional properties.

To Create a Field, Event, or Property:

To create a field, event, or property:

1. Open the property sheet of a type and click the Attributes tab.
2. Click the Add button at the bottom of the tab and select the appropriate option

For general information about creating and working with attributes, see *Attributes (OOM)* on page 65.

Field, Event, and Property Properties

Visual Basic 2005 field, event, and property property sheets contain all the standard attribute tabs along with the VB, the properties of which are listed below:

Property	Description
Compilation Unit	Specifies the compilation unit in which the field will be stored. This field is only available if the parent type is a partial type (allocated to more than one compilation unit).
As New	Specifies that the attribute is created by new object instance.
Shadowing	Specifies the form of shadowing. You can choose between: <ul style="list-style-type: none">• Shadows• Overloads• Overrides
Default	[properties only] Specifies whether the property is a default.
Overriding	[properties only] Specifies the form of overriding available. You can choose between: <ul style="list-style-type: none">• Overridable• NotOverridable• MustOverride
Property Parameters	[properties only] Specifies the parameters of the property.

Working with Properties

Properties are modeled as attributes with a stereotype of <<Property>>, and with one or two linked operations representing the get and/or set accessors.

The visibility of the property is defined by the visibility of the get accessor operation if any, otherwise by that of the set accessor operation.

The Get and Set accessors in Visual Basic 2005 can now have different accessibility settings, as long as Set is more restrictive than Get.

It is possible to add a Property for an existing attribute to access it. The attribute will have the <<PropertyImplementation>> stereotype. The created Property will use the same code as the implemented attribute but starting with an underscore () character. By default, the Property will have a public visibility and will not be persistent.

Working with Events

Events are modeled as attributes with a stereotype of <<Event>>, and with one or two linked operations representing the add and/or remove handlers

You declare events within classes, structures, modules, and interfaces using the Event keyword, as in the following example:

```
Event AnEvent (ByVal EventNumber As Integer)
```

An event is like a message announcing that something important has occurred. The act of broadcasting the message is called raising the event.

Events must be raised within the scope where they are declared. For example, a derived class cannot raise events inherited from a base class.

Any object capable of raising an event is an *event sender*, also known as an *event source*. Forms, controls, and user-defined objects are examples of event senders.

Event handlers are procedures that are called when a corresponding event occurs. You can use any valid subroutine as an event handler. You cannot use a function as an event handler, however, because it cannot return a value to the event source.

Visual Basic uses a standard naming convention for event handlers that combines the name of the event sender, an underscore, and the name of the event. For example, the click event of a button named `button1` would be named `Sub button1_Click`. It is recommended that you use this naming convention when defining event handlers for your own events, but it is not required; you can use any valid subroutine name.

Before an event handler becomes usable, you must first associate it with an event by using either the `Handles` or `AddHandler` statement.

The `WithEvents` statement and `Handles` clause provide a declarative way of specifying event handlers. Events raised by an object declared with `WithEvents` can be handled by any subroutine with a `Handles` clause that names this event. Although the `Handles` clause is the standard way of associating an event with an event handler, it is limited to associating events with event handlers at compile time.

The `AddHandler` and `RemoveHandler` statements are more flexible than the `Handles` clause. They allow you to dynamically connect and disconnect the events with one or more event handlers at run time, and they do not require you to declare object variables using `WithEvents`.

Event Example

The following example shows the `Button` class, which contains three events:

Printer	
- <<Event>>	PaperJam : EventHandler
- <<Event>>	OutOfPaper : EventHandler
- <<Event>>	JobOK : PrinterGoodDelegate

```
Public Class Printer
    Public PaperJam As EventHandler
    Public OutOfPaper As EventHandler
    Public JobOK As PrinterGoodDelegate
End Class
```

Event Handler Example

Printer	
+ <<event>>	Print() : Object
+	Operation_2() : Object

```
...
Public Function Operation_2() As Object Handles Print
    End Function
...
```

Visual Basic 2005 Methods

PowerDesigner models Visual Basic 2005 methods as operations.

For information about creating and working with operations, see *Operations (OOM)* on page 76.

Method Properties

Method property sheets contain all the standard operation tabs along with the VB tab, the properties of which are listed below:

Property	Description
Compilation Unit	Specifies the compilation unit in which the method will be stored. This field is only available if the parent type is a partial type (allocated to more than one compilation unit).
Overridable	Specifies that the method can be overridden.
Overrides	Specifies that the method overrides another.
Handles	Specifies the name of the event that the method handles.
Shadows	Specifies the form of shadowing. You can choose between: <ul style="list-style-type: none"> Shadows Overloads
Library Name	Specifies the library DLL name.
Alias Name	Specifies the alias name.
Character Set	Specifies the character set of the external method.

Shadowing

To define a shadowing by name, select *Shadows* from the *Shadowing* list on the VB tab of the operation property sheet. To define a shadowing by name and signature select *Overloads*. In the following example, class *Derived* inherits from class *Base*:

Operation *F* in class *Derived* overloads operation *F* in class *Base*; and operation *G* in class *Derived* shadows operation *G* in class *Base*:

```

Public Class Derived
  Inherits Base
  Public Overloads Sub F(ByVal i As Integer)
  End Sub
  Public Shadows Sub G(ByVal i As Integer)
  End Sub
End Class
  
```

Method Parameters

You define VB .NET method parameters using operation parameters.

You can define the following parameter modifiers in PowerDesigner:

VB .NET modifier	PowerDesigner equivalent
<i>ByVal</i>	Select <i>In</i> in the Parameter Type box on the parameter property sheet General tab
<i>ByRef</i>	Select <i>In/Out</i> or <i>Out</i> in the Parameter Type box on the parameter property sheet General tab
<i>Optional</i>	Set the <i>Optional</i> extended attribute on the Extended Attributes tab to True
<i>ParamArray</i>	Select the <i>Variable Argument</i> checkbox on the parameter property sheet General tab

Method Implementation

Class methods are implemented by the corresponding interface operations. To define the implementation of the methods of a class, you have to use the To be implemented button in the Operations tab of a class property sheet, then click the Implement button for each method to implement. The method is displayed with the <<*Implement*>> stereotype.

Constructor & Destructor

You design VB .NET *constructors* and *destructors* by clicking the **Add > Default Constructor/Destructor** button in the list of operations of a class. This automatically creates a constructor called New with the Constructor stereotype, and a destructor called Finalize with the Destructor stereotype. Both constructor and destructor are grayed out in the list, which means you cannot modify their definition, but you can still remove them from the list.

Visual Basic 2005 Inheritance and Implementation

PowerDesigner models Visual Basic 2005 inheritance links as standard UML generalizations or realizations.

PowerDesigner models Visual Basic 2005 inheritance links between types as standard UML generalizations (see *Generalizations (OOM)* on page 97).

PowerDesigner models Visual Basic 2005 implementation links between types and interfaces as standard UML realizations (see *Realizations (OOM)* on page 103).

Visual Basic 2005 Custom Attributes

PowerDesigner provides full support for Visual Basic 2005 custom attributes, which allow you to add metadata to your code. This metadata can be accessed by post-processing tools or at run-time to vary the behavior of the system.

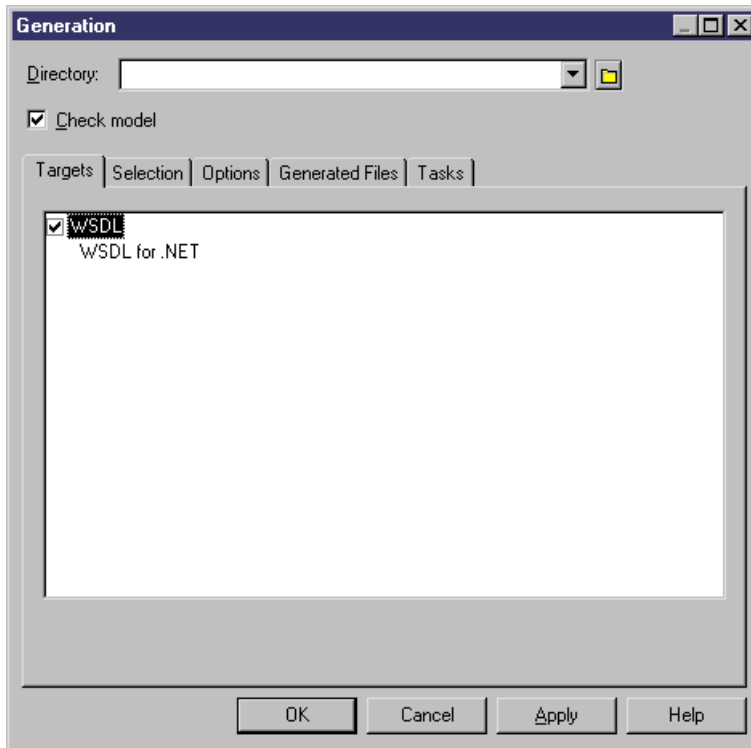

You can use built-in custom attributes, such as System.Attribute and System.ObsoleteAttribute, and also create your own custom attributes to apply to your types.

For general information about modeling this form of metadata in PowerDesigner, see *Annotations (OOM)* on page 109.

Generating Visual Basic 2005 Code

PowerDesigner can generate Visual Basic 2005 code.

1. Select **Language > Generate Visual Basic 2005 Code** to open the Generation dialog box:

2. Enter a directory in which to generate the files, specify whether you want to perform a model check, and select the appropriate target.
3. [optional] Click the Selection tab and specify the objects that you want to generate from. By default, all objects are generated, and PowerDesigner remembers for any subsequent generation the changes you make.
4. [optional] Click the Options tab and set any necessary generation options. For more information, see *Visual Basic 2005 Generation dialog Options tab* on page 504.
5. [optional] Click the Generated Files tab and specify which files will be generated. By default, all objects and compilation units are generated, and PowerDesigner remembers for any subsequent generation the changes you make.
6. [optional] Click the Tasks tab and specify any additional generation tasks to perform. For more information, see *Visual Basic 2005 Generation dialog Tasks tab* on page 505.
7. Click OK to begin generation.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation tab of the Output window, located in the bottom part of the main window.

All Visual Basic 2005 files are generated in the destination directory.

Visual Basic 2005 Generation Dialog Options Tab

The following options are available on this tab:

Option	Description
Generate object ids as documentation tags	Specifies whether to generate object ids for use as documentation tags.
Sort class members primarily by	Specifies the primary method by which class members are sorted. You can choose between: <ul style="list-style-type: none">• Visibility• Type
Class members type sort	Specifies the order by which class members are sorted in terms of their type. You can choose between: <ul style="list-style-type: none">• Methods – Properties - Fields• Properties – Methods - Fields• Fields – Properties - Methods
Class members visibility sort	Specifies the order by which class members are sorted in terms of their visibility. You can choose between: <ul style="list-style-type: none">• Public - Private• Private – Public• None
Generate Visual Studio 2005 project files	Specifies whether to generate project files for use with Visual Studio 2005.
Generate Assembly Info File	Specifies whether to generate information files for assemblies.
Generate Visual Studio Solution File	Specifies whether to generate a solution file for use with Visual Studio 2005.
Generate Web Service Visual Basic code in .asmx file	Specifies whether to generate web services in a .asmx file.
Generate default accessors for navigable associations	Specifies whether to generate default accessors for navigable associations.

Visual Basic 2005 Generation Dialog Tasks Tab

The following tasks are available on this tab:

Task	Description
WSDLDotNet: Generate Web service proxy code	Generates the proxy class
Compile source files	Compiles the source files
Open the solution in Visual Studio	Depends on the Generate Visual Studio 2005 project files option. Opens the generated project in Visual Studio 2005.

Defining Visual Basic 2005 Environment Variables

Variables used for Visual Basic 2005 generation are defined in the General Options dialog box.

For more information on variables and general options, see "Customizing your Modeling Environment" section in the Models chapter of the *Core Features Guide*.

The following variables can be defined in the General Options dialog box:

Variable	Description
CSC	Visual Basic 2005 compiler full path. For example, C:\WINDOWS\Microsoft.NET\Framework\v1.0.3705\csc.exe
WSDL	Web Service proxy generator full path. For example, C:\Program Files\Microsoft Visual Studio .NET\FrameworkSDK\Bin\wsdl.exe

Reverse Engineering Visual Basic 2005 Code

You can reverse engineer Visual Basic 2005 files into an OOM.

1. Select **Language > Reverse Engineer Visual Basic** to open the Reverse Engineer Visual Basic dialog box.
2. Select what form of code you want to reverse engineer. You can choose between:
 - Visual Basic files (.vb)
 - Visual Basic directories
 - Visual Basic projects (.vbproj)
3. Select files, directories, or projects to reverse engineer by clicking the Add button.

Note: You can select multiple files simultaneously using the ctrl or shift keys. You cannot select multiple directories.

The selected files or directories are displayed in the dialog box and the base directory is set to their parent directory. You can change the base directory using the buttons to the right of the field.

4. [optional] Click the Options tab and set any appropriate options. For more information, see *Visual Basic Reverse Engineer dialog Options tab* on page 506.
5. [optional] Click the Preprocessing tab and set any appropriate preprocessing symbols. For more information, see *Visual Basic reverse engineering preprocessing directives* on page 507.
6. Click OK to begin the reverse engineering.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The classes are added to your model. They are visible in the diagram and in the Browser, and are also listed in the Reverse tab of the Output window, located in the lower part of the main window.

Visual Basic Reverse Engineer Dialog Options Tab

The following options are available on this tab:

Option	Description
File encoding	Specifies the default file encoding of the files to reverse engineer
Ignore operation body	Reverses classes without including the body of the code
Ignore comments	Reverses classes without including code comments
Create Associations from classifier-typed attributes	Creates associations between classes and/or interfaces
Create symbols	Creates a symbol for each object in the diagram, if not, reversed objects are only visible in the browser

Option	Description
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>
Preserve file structure	Creates an artifact during reverse engineering in order to be able to regenerate an identical file structure
Mark classifiers not to be generated	Specifies that reversed classifiers (classes and interfaces) will not be generated from the model. To generate the classifier, you must select the Generate check box in its property sheet

Visual Basic Reverse Engineering Preprocessing Directives

Visual Basic files may contain conditional code that needs to be handled by *preprocessing directives* during reverse engineering. A preprocessing directive is a command placed within the source code that directs the compiler to do a certain thing before the rest of the source code is parsed and compiled. The preprocessing directive has the following structure:

```
#directive symbol
```

Where *#* is followed by the name of the directive, and *symbol* is a conditional compiler constant used to select particular sections of code and exclude other sections.

In Visual Basic symbols have values.

In the following example, the *#if* directive is used with symbols *FrenchVersion* and *GermanVersion* to output French or German language versions of the same application from the same source code:

```
#if FrenchVersion Then
' <code specific to French language version>.
#elseif GermanVersion Then
' <code specific to French language version>.
```

```
#Else
' <code specific to other language version>.
#End If
```

You can declare a list of symbols for preprocessing directives. These symbols are parsed by preprocessing directives: if the directive condition is true the statement is kept, otherwise the statement is removed.

Visual Basic Supported Preprocessing Directives

The following directives are supported during preprocessing:

Directive	Description
#Const	Defines a symbol
#If	Evaluates a condition, if the condition is true, the statement following the condition is kept otherwise it is ignored
#Else	If the previous #If test fails, source code following the #Else directive will be included
#Else If	Used with the #if directive, if the previous #If test fails, #Else If includes or exclude source code, depending on the resulting value of its own expression or identifier
#End If	Closes the #If conditional block of code

Note: #Region, #End Region, and #ExternalSource directives are removed from source code.

Defining a Visual Basic Preprocessing Symbol

You can define Visual Basic preprocessing symbols and values in the preprocessing tab of the reverse engineering dialog box.

Symbol names are not case sensitive but they must be unique. Make sure you do not type reserved words like true, false, if, do and so on. You must always assign a value to a symbol, this value can be a string (no " " required), a numeric value, a boolean value or Nothing.

The list of symbols is saved in the model and will be reused when you synchronize your model with existing code using the Synchronize with Generated Files command.

For more information on the Synchronize with Generated Files command see *Synchronizing a Model with Generated Files* on page 282.

You can use the Set As Default button to save the list of symbols in the registry.

1. Select **Language > Reverse engineering Visual Basic.**

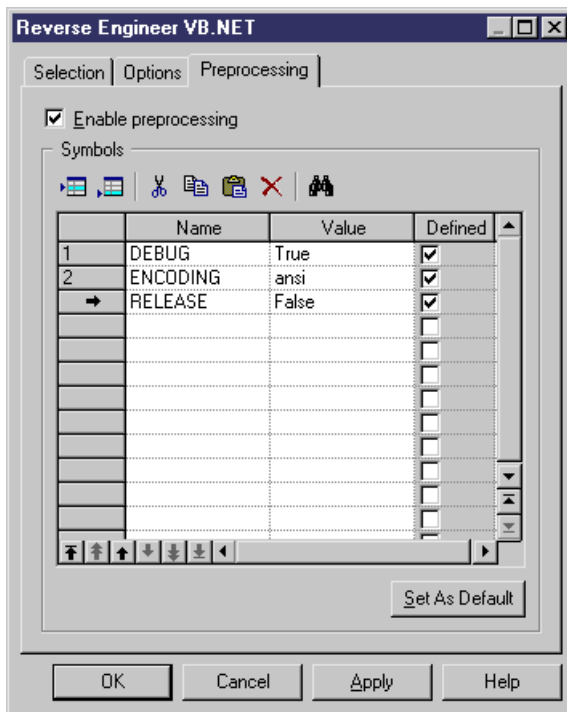

The Reverse Engineering Visual Basic dialog box is displayed.

2. Click the Preprocessing tab, then click the Add a row tool to insert a line in the list.

3. Type symbol names in the Name column.

4. Type symbol value in the Value column.

The Defined check box is automatically selected for each symbol to indicate that the symbol will be taken into account during preprocessing.

5. Click Apply.

PowerDesigner does not support the default namespace in a Visual Studio project. If you define default namespaces in your projects, you should avoid reverse engineering the entire solution. It is better to reverse engineer each project separately.

CHAPTER 19 Working with C#

PowerDesigner supports the modeling of C# programs including round-trip engineering.

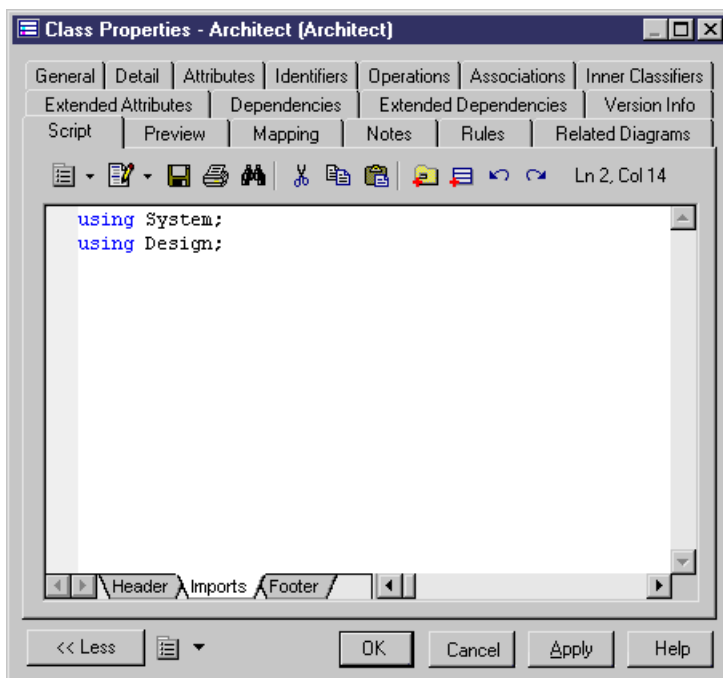

What Is Automatically Generated

During C# generation, each main object (class, interface, and so on) generates a source file with the .cs extension. Inner classifiers are generated in the source of the container classifier.

Using Directive

The *using* directive can appear at the beginning of the script of each generated file.

In PowerDesigner, you can define a using directive in the Script\Imports tab of the property sheet of a main object. You can type the using statement or use the Import Folder or Import Classifier tools in the Imports tab.

Supported C# Objects

This section develops the C# concepts supported in PowerDesigner.

Inheritance & Implementation

You design C# *inheritance* using a *generalization* link between classes.

You design C# *implementation* using a *realization* link between a class and an interface.

Namespace

You define a C# *namespace* using a package.

Only packages with the Use Parent Namespace check box deselected become C# namespaces.

In the following example, class Architect is declared in package Design which is a sub-package of Factory. The namespace declaration is the following:

```
namespace Factory.Design
{
    public class Architect
    {
    }
}
```

Classifiers defined directly at the model level fall into the C# global namespace.

Project

You can reverse engineer C# projects when you select C# projects from the Reverse Engineer list in the Reverse Engineer C# dialog box.

Make sure you reverse engineer each project into a separate model.

Assembly properties are reverse engineered as follow:

C# assembly properties	PowerDesigner equivalent
Title	Name of the model
Description	Description of the model
Configuration	AssemblyConfiguration extended attribute
Company	AssemblyCompany extended attribute
Copyright	AssemblyCopyright extended attribute
Product	AssemblyProduct extended attribute
Trademark	AssemblyTrademark extended attribute

C# assembly properties	PowerDesigner equivalent
Version	AssemblyVersion extended attribute
Culture	AssemblyCulture extended attribute
AssemblyVersionAttribute System.CLSCompliant AssemblyFlagsAttribute	Stored in CustomAttributes extended attribute

Project properties are reverse engineered as extended attributes whether they have a value or not. For example, the default HTML page layout is saved in extended attribute `DefaultHTMLPageLayout`.

You can use the Ellipsis button in the Value column to modify the extended attribute value, however you should be very cautious when performing such changes as they may jeopardize model generation.

Accessibility

To define *accessibility* for a class, an interface, or a method, you have to use the *visibility* property in PowerDesigner.

The following accessibility attributes are supported in PowerDesigner:

C# accessibility	PowerDesigner visibility
<i>Public</i> (no restriction)	<i>Public</i>
<i>Private</i> (access limited to the containing type)	<i>Private</i>
<i>Protected</i> (access limited to the containing class or types derived from the containing class)	<i>Protected</i>
<i>Internal</i> (access limited to current program)	<i>Internal</i>
<i>Protected internal</i> (access limited to this program or types derived from the containing class)	<i>Protected internal</i>

Class

You design a C# *class* using a class in PowerDesigner. C# classes can contain events, variables, constants, methods, constructors, properties, and indexers.

The following specific classes are also supported in PowerDesigner:

- *New* class is used to declare a member with the same name or signature as an inherited member. To design a new class, you have to set the class *new* extended attribute to True. In the following example, class `DialogBox` inherits from class `Window`. Class `Window` contains an inner classifier `Control`, and so does class `DialogBox`. You do not want class

DialogBox to inherit from the control defined in Window, to do so, you have to set the new extended attribute to True, in the Control class inner to DialogBox:

```

{
public class DialogBox : Window
{
    public new class Control
    {
    }
}
}

```

- *Abstract* class is equivalent to an abstract class. To design this type of class you need to create a class and select the *Abstract* check box in the General tab of the class property sheet.

```

{
public abstract class Client
{
    private int Name;
    private int ID;
}
}

```

- *Sealed* class is equivalent to a final class. To design this type of class, you need to create a class and select the *Final* check box in the General tab of the class property sheet.

```

{
public sealed class SealedClass
{
    private int A1;
    private int A2;
}
}

```

```
}
}
```

Struct

You design a C# *struct* using a class with the <<structure>> stereotype. A struct can implement interfaces but does not support inheritance; it can contain events, variables, constants, methods, constructors, and properties.

The following struct contains two attributes:

Point
Y : Integer
X : Integer
+ <<Constructor>> New()

```
{
public struct Point
{
public int New()
{
return 0;
}
private int x;
private int y;
}
}
```

Enumeration

You design a C# *enumeration* using a class with the <<enumeration>> stereotype. The code of the class attributes is used as enumeration values.

- *Data Type*: You set the enumeration data type using the *EnumDataType* extended attribute of the enumeration. You can type for example Byte, Short, or Long in the value column of the extended attribute
- *Initial Expression*: You set the enumeration *Initial Expression* by defining a value in the *Initial Value* box of an enum attribute

<<enumeration>> Color
- Red : Object
- Blue : Object
- Green : Object
- Max : Object = Blue

```
{
public enum Color : colors
{
Red,
Blue,
Green,
Max = Blue
}
```

```
}  
}
```

Interface

You design a C# *interface* using an interface in PowerDesigner. C# interfaces can contain events, properties, indexers and methods; they do not support variables, constants, and constructors.

Nested Types

You design a C# *nested type* using an inner class or interface.

Custom Attributes

To define *custom attributes* for a class, an interface, a variable, a parameter or a method, you have to use the *CustomAttributes* extended attribute in PowerDesigner. You can use the CustomAttributes input box to type all the custom attributes you wish to add using the correct C# syntax.

Fields

You design a C# *field* using an attribute in PowerDesigner.

The following table summarizes the C# field modifiers supported in PowerDesigner:

C# field modifiers	PowerDesigner equivalent
<i>Static</i> field	<i>Static</i> property selected
<i>New</i> field	<i>New</i> extended attribute set to True
<i>Unsafe</i> field	<i>Unsafe</i> extended attribute set to True
<i>Public</i> field	<i>Public</i> visibility

C# field modifiers	PowerDesigner equivalent
<i>Protected</i> field	<i>Protected</i> visibility
<i>Internal</i> field	<i>Internal</i> visibility
<i>Private</i> field	<i>Private</i> visibility
<i>ReadOnly</i> field	<i>Read-only</i> changeability
<i>Volatile</i> field	<i>Volatile</i> property selected

- *Data Type*: You define the data type of a field using the attribute Data Type property
- *Initial Value*: You define the initial value of a field using the attribute Initial Value property

Property

To design a C# *property* you have to design an attribute with the <<*Property*>> stereotype.

When you do so, another attribute with the <<*PropertyImplementation*>> stereotype is automatically created, it is displayed with an underscore sign in the list of attributes. The corresponding getter and setter operations are also automatically created.

You can get rid of the implementation attribute.

If you remove both getter and setter operations, the attribute no longer has the <<*Property*>> stereotype.

When you define a <<*Property*>> attribute, the attribute changeability and the getter/setter operations are tightly related as explained in the following table:

Operations	Property attribute changeability
If you keep both getter and setter operations	Property is Changeable
If you remove the setter operation of a changeable property	Property becomes Read-only
If you remove the getter operation of a changeable property	Property becomes Write-only

On the other hand, if you modify the property changeability, operations will reflect this change, for example, if you turn a changeable property into a read-only property, the setter operation is automatically removed.

In the following example, class Employee contains 2 properties. The Setter operation has been removed for property TimeReport:

Employee	
- <<Property>>	Function :int
- <<Property>>	TimeReport :int
- <<PropertyImplementation>>	_Function :int
- <<PropertyImplementation>>	_TimeReport :int
+ <<Setter>>	set_Function(int value) :void
+ <<Getter>>	get_Function() :int
+ <<Getter>>	get_TimeReport() :int

```

{
public class Employee
{
private int _Function;
private int _TimeReport;
// Property Function
private int Function
{
get
{
return _Function;
}
set
{
if (this._Function != value)
this._Function = value;
}
}
// Property TimeReport
private int TimeReport
{
get
{
return _TimeReport;
}
}
}
}

```

The following table lists the different property modifiers supported in PowerDesigner:

C# property modifiers	PowerDesigner equivalent
<i>Abstract</i>	<i>Abstract extended attribute set to True</i>
<i>Extern</i>	<i>Extern extended attribute set to True</i>
<i>Override</i>	<i>Override extended attribute set to True</i>
<i>Sealed</i>	<i>Sealed extended attribute set to True</i>
<i>Unsafe</i>	<i>Unsafe extended attribute set to True</i>
<i>Virtual</i>	<i>Virtual extended attribute set to True</i>

Indexer

You design a C# *indexer* using an attribute with the `<<Indexer>>` stereotype. Another attribute with the `<<IndexerImplementation>>` stereotype is automatically created, it is displayed with an underscore sign in the list of attributes. The corresponding getter and setter operations are also automatically created.

You can get rid of the implementation attribute.

If you remove both getter and setter operations, the attribute no longer has the `<<Indexer>>` stereotype.

When you define a `<<Indexer>>` attribute, the attribute changeability and the getter/setter operations are tightly related as explained in the following table:

Operations	Indexer attribute changeability
If you keep both getter and setter operations	Indexer is Changeable
If you remove the setter operation of a changeable property	Indexer becomes Read-only
If you remove the getter operation of a changeable property	Indexer becomes Write-only

On the other hand, if you modify the indexer changeability, operations will reflect this change, for example, if you turn a changeable indexer into a read-only indexer, the setter operation is automatically removed.

In the following example, class `Person` contains indexer attribute `Item`. The parameter used to sort the property is `String Name`:

Person	
-	<<Indexer>> <code>Item</code> : int
-	<<IndexerImplementation>> <code>_childAges</code> : Hashtable
+	<<Setter>> <code>set_Item (int value)</code> : void
+	<<Getter>> <code>get_Item ()</code> : int

```
public class Person
{
    private Hashtable _childAges;
    // Indexer Item
    private int this[String name]
    {
        get
        {
            return (int)_ChildAges[name];
        }
        set
        {
            _ChildAges[name] = value;
        }
    }
}
```

```

}
}
Person someone;
someone ["Alice"] = 3;
someone ["Elvis"] = 5;

```

The following table lists the different indexer modifiers supported in PowerDesigner:

C# property modifier	PowerDesigner equivalent
<i>New</i>	<i>New extended attribute set to True</i>
<i>Unsafe</i>	<i>Unsafe extended attribute set to True</i>
<i>Virtual</i>	<i>Virtual extended attribute set to True</i>
<i>Override</i>	<i>Override extended attribute set to True</i>
<i>Extern</i>	<i>Extern extended attribute set to True</i>
<i>Abstract</i>	<i>Abstract extended attribute set to True</i>
<i>Sealed</i>	<i>Sealed extended attribute set to True</i>

Parameters

Type a value in the value box of the *Indexer parameters* extended attribute to specify which value of the property attribute is to be used as parameter.

Method

You design a C# *method* using an operation.

The following table summarizes the different methods supported in PowerDesigner:

C# method	PowerDesigner equivalent
<i>Extern</i>	Select the <i>Extern</i> check box in the C# tab of the operation property sheet
<i>New</i>	Select the <i>New</i> check box in the C# tab of the operation property sheet
<i>Virtual</i>	Select the <i>Virtual</i> check box in the C# tab of the operation property sheet
<i>Override</i>	Select the <i>Override</i> check box in the C# tab of the operation property sheet
<i>Unsafe</i>	Select the <i>Unsafe</i> check box in the C# tab of the operation property sheet
<i>Explicit</i>	Select the <i>Explicit</i> check box in the C# tab of the operation property sheet

C# method	PowerDesigner equivalent
<i>Static</i>	Select the <i>Static</i> check box in the General tab of the operation property sheet
<i>Sealed</i>	Select the <i>Final</i> check box in the General tab of the operation property sheet
<i>Abstract</i>	Select the <i>Abstract</i> check box in the General tab of the operation property sheet

New

When a class inherits from another class and contains methods with identical signature as in the parent class, the *New* check box is automatically selected to make the child method prevail over the parent method.

BaseInitializer and ThisInitializer for Constructors

The *Base Initializer* property in the C# tab of the operation property sheet is used to create an instance constructor initializer of the form `base`. It causes an instance constructor from the base class to be invoked.

The *This Initializer* property in the C# tab of the operation property sheet is also used to create an instance constructor initializer, it causes an instance constructor from the class itself to be invoked.

In the following example, class B inherits from class A. You define a Base Initializer extended attribute in class B constructor, this extended attribute will be used to initialize class A constructor:

```

internal class B : A
{
    public B(int x, int y) : base(x + y, x - y)
    {}
}
  
```

Method Parameters

You define C# method parameters using operation parameters.

You can define the following parameter modifiers in PowerDesigner:

C# modifier	PowerDesigner equivalent
<i>[none]</i>	Select <i>In</i> in the Parameter Type box on the parameter property sheet General tab
<i>ref</i>	Select <i>In/Out</i> in the Parameter Type box on the parameter property sheet General tab
<i>out</i>	Select <i>Out</i> in the Parameter Type box on the parameter property sheet General tab
...	Select the <i>Variable Argument</i> checkbox on the parameter property sheet General tab

Method Implementation

Class methods are implemented by the corresponding interface operations. To define the implementation of the methods of a class, you have to use the To be implemented button in the Operations tab of a class property sheet, then click the Implement button for each method to implement. The method is displayed with the <<Implement>> stereotype.

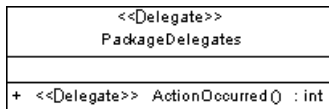

Constructor & Destructor

You design C# *constructors* and *destructors* by clicking the *AddDefault Constructor/ Destructor* button in the list of operations of a class. This automatically creates a constructor with the Constructor stereotype, and a destructor with the Destructor stereotype. Both constructor and destructor are grayed out in the list, which means you cannot modify their definition, but you can still remove them from the list.

Delegate

You can design the following types of C# *delegates*:

- To create a delegate at the namespace level, create a class with the <<Delegate>> stereotype, and add an operation with the <<Delegate>> stereotype to this class and define a visibility for this operation. This visibility becomes the visibility of the delegate

```

{
public delegate int ActionOccurred();
}
  
```

- To create a delegate in a class, or structure, you just have to create an operation with the <<Delegate>> stereotype. In the following example, Class worker contains an internal delegate designed as an operation with the <<Delegate>> stereotype

Worker
+ <<Delegate>> WorkStarted ()

```
{
public class Worker
{
public delegate WorkStarted();
}
}
```

Event

You design a C# *event* using an attribute with the <<Event>> stereotype.

Button
- <<Event>> Click : Object
- <<Event>> DoubleClick : Object
- <<Event>> RightClick : Object

Operator Method

You design a C# *operator* using an operation with the <<Operator>> stereotype. Make sure the <<Operator>> operation has the Public visibility and the Static property selected.

To define an *external operator*, you have to set the extern extended attribute of the operation to True. The new, virtual and override extended attributes are not valid for operators.

The operator *token* (like +, -, !, ~, or ++ for example) is the name of the method.

IntVector
+ <<Operator>> Oper1 (+, -) : int

Conversion Operator Method

You design a C# *conversion operator* using an operation with the <<ConversionOperator>> stereotype.

You also need to declare the conversion operator using the *explicit* or *implicit* keywords. You define the conversion operator keyword by selecting the implicit or explicit value of the *scope* extended attribute.

In the following example, class Digit contains one explicit conversion operators and one implicit conversion operator:

<<struct>> Digit
- value : byte
+ <<constructor>> Digit (byte value)
+ <<ConversionOperator>> byte (Digit d) : byte
+ <<ConversionOperator>> Digit (byte b) : Digit

```
public struct Digit
{
    public Digit(byte value)
    {
        if (value < 0 || value > 9) throw new ArgumentException();
        this.value = value;
    }
    public static implicit operator byte(Digit d)
    {
        return d.value;
    }

    public static explicit operator Digit(byte b)
    {
        return new Digit(b);
    }
    private byte value;
}
```

Documentation Tags

To generate documentation tags, you should use the Comment box in property sheets. You can use any documentation tag before and after documentation, for example you can type <summary> and </summary>.

If you add a tag, the documentation is preceded by /// in the generated code. During reverse engineering, the / signs used to identify documentation are removed and the start and end documentation tags are automatically added.

In the following example, you add a comment to class Employee:

The following code is generated:

```
/// <summary>
/// this is documentation
/// this is documentation
/// </summary>
```

Generating for C#

This section explains some of the features of the C# object language in order to generate C# code from objects in the OOM.

Defining C# Environment Variables

Variables used for C# generation are defined in the General Options dialog box.

For more information on variables and general options, see "Customizing your Modeling Environment" section in the Models chapter of the *Core Features Guide*.

The following variables can be defined in the General Options dialog box:

Variable	Description
CSC	C# compiler full path. For example, C:\WINDOWS\Microsoft.NET\Framework\v1.0.3705\csc.exe

Variable	Description
WSDL	Web Service proxy generator full path. For example, C:\Program Files\Microsoft Visual Studio .NET\FrameworkSDK\Bin\wsdl.exe

Selecting C# Generation Options

You can set the following options, available from the Options tab of the Generation dialog box in C#:

Options	Description
Generate Web Service C# code in .ASMX file	Generates the C# code in the .ASMX file
Generate Visual Studio .NET project files	Generates the files of the Visual Studio .NET project. A solution file is generated together with several project files, each project corresponding to a model or a package with the <<Assembly>> stereotype
Generate object ids as documentation tags	Generates information used for reverse engineering like object identifiers (@pdoid) that are generated as documentation tags. If you do not want these tags to be generated, you have to set this option to False
Visual Studio .NET version	Indicates the version number of Visual Studio .NET

Selecting C# Generation Tasks

The Tasks category contains the following commands:

Options	Description
Compile C# source files	Compiles the source files
Generate Web service proxy code (WSDL)	Generates the proxy class
Open the solution in Visual Studio .NET	If you selected the Generate Visual Studio .NET project files option, this task allows to open the solution in the Visual Studio .NET development environment

Generating C# Files

The files generated are generated with the .cs extension. A generation log file is also created after generation.

1. Select **Language > Generate C# Code** to display the Generation dialog box.
2. Type a destination directory for the generated file in the Directory box.

or

Click the Select a Path button to the right of the Directory box and browse to select a directory path.

3. Click the Selection tab, then select the objects to include in the generation from the tabs at the bottom of the page.

Note: All classes of the model, including those grouped into packages, are selected and displayed by default. You use the Select tools to the right of the Folder Selection list to modify the selection. The Include Sub-Packages tool allows you to include all classes located within packages.

4. Click the Options tab to display the Options tab.
5. <optional> Select the Check Model check box if you want to verify the validity of your model before generation.
6. Select a value for each required option.
7. Click the Tasks tab, then select the required task(s).
8. Click OK to generate.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation tab of the Output window, located in the bottom part of the main window.

All C# files are generated in the destination directory.

Reverse Engineering C#

You can reverse engineer C# files into an OOM.

In the Selection tab, you can select to reverse engineer files, directories or projects.

You can also define a base directory. The base directory is the common root directory for all the files to reverse engineer. This base directory will be used during regeneration to recreate the exact file structure of the reverse engineered files.

Edit Source

You can right-click the files to reverse engineer and select the Edit command to view the content of your files. To use this command you have to associate the file extension with an editor in the General Options\Editor dialog box.

Selecting C# Reverse Engineering Options

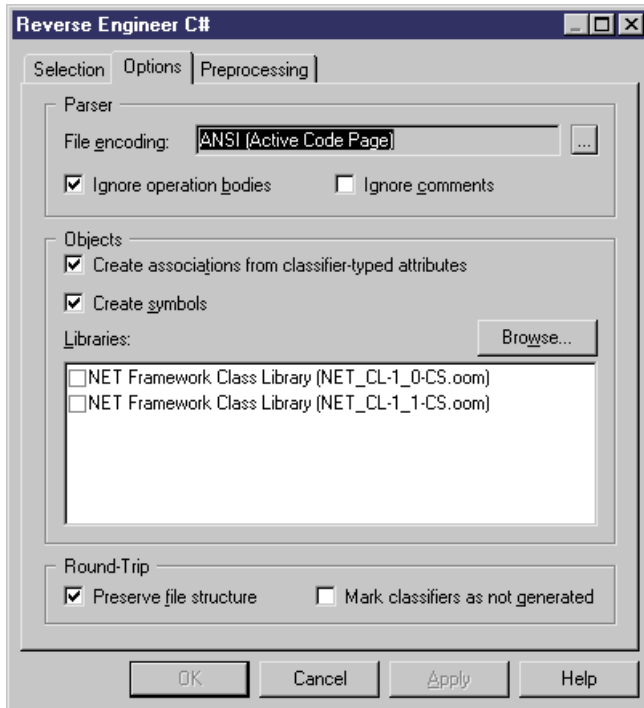

You define the following C# reverse engineering option from the Reverse Engineer C# dialog box:

Option	Result of selection
File encoding	Allows you to modify the default file encoding of the files to reverse engineer
Ignore operation body	Reverses classes without including the body of the code
Ignore comments	Reverses classes without including code comments
Create Associations from classifier-typed attributes	Creates associations between classes and/or interfaces
Create symbols	Creates a symbol for each object in the diagram, if not, reversed objects are only visible in the browser
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>
Preserve file structure	Creates an artifact during reverse engineering in order to be able to regenerate an identical file structure.
Mark classifiers not to be generated	Reversed classifiers (classes and interfaces) will not be generated from the model. To generate the classifier, you must select the Generate check box in its property sheet

Defining C# Reverse Engineering Options

To define C# reverse engineering options:

1. Select **Language > Reverse Engineer C#**.
2. Click the Options tab to display the Options tab.

3. Select or clear reverse engineering options.
4. Browse to the Library directory, if required.
5. Click Apply and Cancel.

C# Reverse Engineering Preprocessing

C# files may contain conditional code that needs to be handled by *preprocessing directives* during reverse engineering. A preprocessing directive is a command placed within the source code that directs the compiler to do a certain thing before the rest of the source code is parsed and compiled. The preprocessing directive has the following structure:

```
#directive symbol
```

Where *#* is followed by the name of the directive, and *symbol* is a conditional compiler constant used to select particular sections of code and exclude other sections.

In C#, symbols have no value, they can be true or false.

In the following example, the #if directive is used with symbol DEBUG to output a certain message when DEBUG symbol is true, if DEBUG symbol is false, another output message is displayed.

```
using System;
public class MyClass
{
    public static void Main()
    {
        #if DEBUG
            Console.WriteLine("DEBUG version");
        #else
            Console.WriteLine("RELEASE version");
        #endif
    }
}
```

You can declare a list of symbols for preprocessing directives. These symbols are parsed by preprocessing directives: if the directive condition is true the statement is kept, otherwise the statement is removed.

C# Supported Preprocessing Directives

The following directives are supported during preprocessing:

Directive	Description
#define	Defines a symbol
#undefine	Removes a previous definition of the symbol
#if	Evaluates a condition, if the condition is true, the statement following the condition is kept otherwise it is ignored
#elif	Used with the #if directive, if the previous #if test fails, #elif includes or exclude source code, depending on the resulting value of its own expression or identifier
#endif	Closes the #if conditional block of code
#warning	Displays a warning message if the condition is true
#error	Displays an error message if the condition is true

Note: #region, #endregion, and #line directives are removed from source code.

Defining a C# Preprocessing Symbol

You can define C# preprocessing symbols in the preprocessing tab of the reverse engineering dialog box.

Symbol names are case sensitive and must be unique. Make sure you do not type reserved words like true, false, if, do and so on.

The list of symbols is saved in the model and will be reused when you synchronize your model with existing code using the Synchronize with Generated Files command.

For more information on the synchronize with generated files command see *Synchronizing a Model with Generated Files* on page 282.

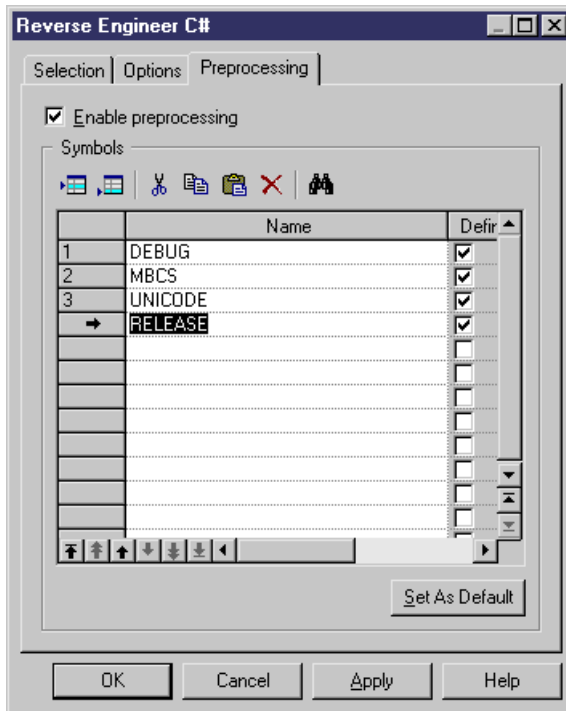

You can use the Set As Default button to save the list of symbols in the registry.

1. Select **Language > Reverse engineering C#**.

The Reverse Engineering C# dialog box is displayed.

2. Click the Preprocessing tab, then click the Add a row tool to insert a line in the list.
3. Type symbol names in the Name column.

The Defined check box is automatically selected for each symbol to indicate that the symbol will be taken into account during preprocessing.

4. Click Apply.

C# Reverse Engineering with Preprocessing

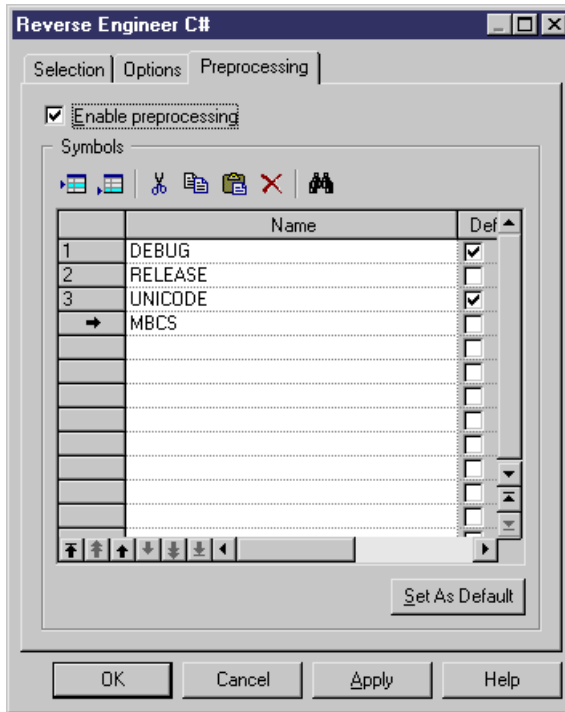

Preprocessing is an option you can enable or disable when you reverse engineer a model.

1. Select **Language > Reverse engineering C#**.

The Reverse Engineering C# dialog box is displayed.

2. Select files to reverse engineer in the Selection tab.
3. Select reverse engineering options in the Options tab.

4. Select the Enable preprocessing check box in the Preprocessing tab.
5. Select symbols in the list of symbols.

6. Click OK to start reverse engineering.

When preprocessing is over the code is passed to reverse engineering.

Reverse Engineering C# Files

You can reverse engineer C# files

PowerDesigner does not support the default namespace in a Visual Studio project. If you define default namespaces in your projects, you should avoid reverse engineering the entire solution. It is better to reverse engineer each project separately.

1. Select **Language > Reverse Engineer C#** to display the Reverse Engineer C# dialog box.
2. Select to reverse engineer files or directories from the Reverse Engineering list.
3. Click the Add button in the Selection tab.

A standard Open dialog box is displayed.

4. Select the items or directory you want to reverse engineer.

Note: You select several files simultaneously using the ctrl or shift keys. You cannot select several directories.

The Reverse C# dialog box displays the files you selected.

5. Click OK.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The classes are added to your model. They are visible in the diagram and in the Browser. They are also listed in the Reverse tab of the Output window, located in the lower part of the main window.

CHAPTER 20 Working with C# 2.0

PowerDesigner provides full support for modeling all aspects of C# 2.0 including round-trip engineering.

C# 2.0 is a modern, type-safe, object-oriented language that combines the advantages of rapid development with the power of C++.

PowerDesigner can be used as a standalone product and as a plug-in for the Visual Studio 2005 development environment, allowing you to integrate its enterprise-level modeling capabilities in your standard .NET workflow. For more information, see the *Working with the VS2005 Plug-in* manual.

Custom C# 2.0 Tools

In addition to PowerDesigner's standard pallets, the following custom tools are available to help you rapidly develop your class and composite structure diagrams:

Icon	Tool
	Assembly – a collection of C# files (see <i>C# 2.0 Assemblies</i> on page 535).
	Custom Attribute – for adding metadata (see <i>C# 2.0 Custom Attributes</i> on page 553).
	Delegate – type-safe reference classes (see <i>C# 2.0 Delegates</i> on page 545).
	Enum – sets of named constants (see <i>C# 2.0 Enums</i> on page 546).
	Struct – lightweight types (see <i>C# 2.0 Structs</i> on page 544).

C# 2.0 Assemblies

An assembly is a collection of C# files that forms a DLL or executable. PowerDesigner provides support for both:

- single-assembly models, where the model represents the assembly, and
- multi-assembly models, where each assembly appears directly below the model in the Browser tree, and is modeled as a standard UML package with a stereotype of <<Assembly>>.

Creating an Assembly

PowerDesigner supports both single-assembly and multi-assembly models. By default, when you create a C# OOM, the model itself represents an assembly.

To Continue with a Single-assembly Model:

In the top-level diagram, insert a type or a namespace. The model will default to a single-module assembly, with the model root representing the assembly.

To Work with a Multi-assembly Model:

In the top-level diagram, insert an assembly in any of the following ways:

- Use the Assembly tool in the C# 2.0 diagram Palette.
- Select **Model > Assembly Objects** to access the List of Assembly Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Assembly**.

Note that, if these options are not available to you, then you are currently working with a single-assembly model. See *Converting a single-assembly model to a multi-assembly model* on page 536.

The model will default to a multimodule assembly, with each assembly represented by a standard UML package symbol, and appearing directly below the model in the Browser tree.

Converting a Single-assembly Model to a Multi-assembly Model

You may find that you begin by designing a single-module assembly and then need to convert your design to accommodate a multi-module assembly.

1. Right-click the Browser entry for the single-assembly model and select Convert to Multi-Assembly Model from the contextual menu.
2. The Create an Assembly dialog box will open, inviting you to enter a name for the assembly that will contain all the types in your model. Enter a name and then click OK.

PowerDesigner converts the single-assembly model into a multi-assembly model by inserting a new assembly directly beneath the model root to contain all the types present in the model. You can add new assemblies as necessary but only as direct children of the model root.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Assembly Properties

Assembly property sheets contains all the standard package tabs along with the C#-specific tabs listed in the sections below.

Assembly Property Sheet Application Tab

The Application tab contains the following properties:

Property	Description
Generate Project File	Specifies whether to generate a Visual Studio 2005 project file for the assembly.
Project Filename	Specifies the name of the project in Visual Studio. The default is the value of the assembly code property.
Assembly Name	Specifies the name of the assembly in Visual Studio. The default is the value of the assembly code property.
Root Namespace	Specifies the name of the root namespace in Visual Studio. The default is the value of the assembly code property.
Output Type	Specifies the type of application being designed. You can choose between: <ul style="list-style-type: none"> • Class library • Windows Application • Console Application
Project GUID	Specifies a unique GUID for the project. This field will be completed automatically at generation time.

Assembly Property Sheet Assembly Information Tab

The Assembly Information tab contains the following properties:

Property	Description
Generate Assembly Information	Specifies whether to generate an assembly manifest file.
Title	Specifies a title for the assembly manifest. This field is linked to the Name field on the General tab.
Description	Specifies an optional description for the assembly manifest.
Company	Specifies a company name for the assembly manifest.
Product	Specifies a product name for the assembly manifest.
Copyright	Specifies a copyright notice for the assembly manifest.
Trademark	Specifies a trademark for the assembly manifest.
Culture	Specifies which culture the assembly supports.
Version	Specifies the version of the assembly.
File Version	Specifies a version number that instructs the compiler to use a specific version for the Win32 file version resource.

Property	Description
GUID	Specifies a unique GUID that identifies the assembly.
Make assembly COM-Visible	Specifies whether types within the assembly will be accessible to COM.

C# 2.0 Compilation Units

By default, PowerDesigner generates one source file for each class, interface, delegate, or other type, and bases the source directory structure on the namespaces defined in the model.

You may want instead to group multiple classifiers in a single source file and/or construct a directory structure independent of your namespaces.

A compilation-unit allows you to group multiple types in a single source file. It consists of zero or more using-directives followed by zero or more global-attributes followed by zero or more namespace-member-declarations. PowerDesigner models C# compilation units as artifacts with a stereotype of <<Source>> and allows you to construct a hierarchy of source directories using folders.

Creating a Compilation Unit

You can create compilation units from the Browser or from the property sheets of types. Compilation units do not have diagram symbols, and are only visible inside the Artifacts folder in the Browser.

Creating an Empty Compilation Unit from the Browser

To create an empty compilation unit from the Browser:

1. Right-click the model or an artifact folder (see *Creating a generation folder structure* on page 540) in the Browser, and select **New > Source** from the contextual menu. The property sheet of the new compilation unit opens.
2. Specify a name for the compilation unit, being sure to retain the .cs extension, and then click OK. The compilation unit is listed in the Browser inside the Artifacts folder. For information on populating it, see *Adding types to compilation units* on page 539.

Creating and Populating a Compilation Unit from the Property Sheet of a Type:

To create and populate a Cc compilation unit from the property sheet of a type:

1. Open the type's property sheet and click the Generated Files tab. If the type is not currently associated with a compilation unit, then the tab will resemble the following:

3. Specify objects to add to the compilation unit by selecting their checkboxes. Note that almost any model object (including other compilation units) can be added to a compilation unit.
4. Click OK to return to the compilation unit property sheet. The selected objects are now listed on the Objects tab.
5. Click OK to close the compilation unit property sheet. The selected objects are now listed beneath the compilation unit in the Browser.

You can also create a compilation unit from the property sheet of a type:

Adding a Type to a Compilation Unit from the Type Property Sheet

To add a type to a compilation unit from the type property sheet:

1. Double-click the type's diagram symbol or browser entry to open its property sheet, and then click the Generated Files tab.
2. In the Artifact(s) column, click the Add/Remove tool to open a selection window listing all the compilation unit available in the model.
3. Specify the compilation units to which the type will be added by selecting their checkboxes. Note that types can be added to multiple compilation units. In this case, they will be generated as partial types (see *Partial Types* on page 543) and you can specify in which compilation unit each of their attributes and methods will be generated.
4. Click OK to return to the type property sheet. The selected compilation units are now listed on the Generated Files tab.
5. Click OK to close the type property sheet. The type is now listed in the Browser, beneath the selected compilation unit(s).

Creating a Generation Folder Structure

You can control the directory structure in which your compilation units will be generated by using artifact folders.

1. Right-click the model or an existing folder within the Artifacts folder in the Browser, and select **New > Artifact Folder** from the contextual menu. The property sheet of the new folder opens.
2. Specify a name for the folder, and then click OK. The new folder is listed in the Browser.

Adding Compilation Units to Folders

To add a compilation unit to a folder, simply drag its browser entry and drop it onto the folder browser entry. Note that folders can contain only compilation units and/or other folders. Thus, to place a type in the generation folder hierarchy, you must first add it to a compilation unit.

Alternatively, you can create a new compilation unit directly in a folder by right-clicking its browser entry, and selecting **New > Source** from the contextual menu.

Previewing the Code to Be Generated for a Compilation Unit

You can preview the code that will be generated for your compilation unit at any time, by opening its property sheet and clicking the Preview tab.

C# 2.0 Namespaces

Namespaces restrict the scope of an object's name. Each class or other type must have a unique name within the namespace.

PowerDesigner models namespaces as standard packages with the Use Parent Namespace property set to false. For information about creating and working with packages, see *Packages (OOM)* on page 48.

In the following example, class Architect is declared in package Design which is a sub-package of Factory. The namespace declaration is the following:

```
namespace Factory.Design
{
    public class Architect
    {
    }
}
```

This structure, part of the NewProduct model, appears in the PowerDesigner Browser as follows:

Classifiers defined directly at the model level fall into the C# global namespace.

C# 2.0 Classes

PowerDesigner models C# 2.0 classes as standard UML classes, but with additional properties.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

In the following example, class DialogBox inherits from class Window, which contains an inner classifier Control, as does class DialogBox:

```

{
public class DialogBox : Window
{
    public new class Control
    {
    }
}
}

```

In the following example, the class Client is defined as abstract by selecting the Abstract check box in the General tab of the class property sheet.

```

{
public abstract class Client
{
    private int Name;
    private int ID;
}
}

```

In the following example, the class SealedClient is defined as sealed by selecting the Final check box in the General tab of the class property sheet:

```

{
public sealed class SealedClass
{
    private int A1;
    private int A2;
}
}

```

C# Class Properties

C# class property sheets contain all the standard class tabs along with the C# tab, the properties of which are listed below:

Property	Description
Static	Specifies the static modifier for the class declaration.
Sealed	Specifies the sealed modifier for the class declaration.
New	Specifies the new modifier for the class declaration.
Unsafe	Specifies the unsafe modifier for the class declaration.

Partial Types

Types may belong to more than one compilation unit. Partial types are prefixed with the keyword `partial`, as in the following example:

```
public partial class Server
{
    private int start;
}
```

In this case, you can specify to which compilation unit, each field and method will be assigned, using the Compilation Unit box on the C# tab of their property sheets (see *Field properties* on page 547).

For partial types that contain inner types, you can specify the compilation unit to which each inner type will be assigned as follows:

Specifying the Compilation Unit to Which an Inner Type Belongs

To specify the compilation unit to which an inner type belongs:

1. Open the property sheet of the container type and click the Inner Classifiers tab.
2. Click the Customize Columns and Filter tool, select the CompilationUnit Column Heading from the selection box, and then click OK to return to the tab. The CompilationUnit column is now displayed on the tab.
3. Click in the CompilationUnit column to reveal a list of available compilation units, select one, and click OK to close the property sheet..

C# 2.0 Interfaces

PowerDesigner models C# 2.0 interfaces as standard UML interfaces, with additional properties.

For information about creating and working with interfaces, see *Interfaces (OOM)* on page 52.

C# interfaces can contain events, properties, indexers and methods; they do not support variables, constants, and constructors.

C# Interface Properties

C# interface property sheets contain all the standard interface tabs along with the C# tab, the properties of which are listed below:

Property	Description
New	Specifies the new modifier for the interface declaration.
Unsafe	Specifies the unsafe modifier for the interface declaration.

C# 2.0 Structs

Structs are lightweight types that make fewer demands on the operating system and on memory than conventional classes. PowerDesigner models C# 2.0 structs as classes with a stereotype of <<Structure>>.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

A struct can implement interfaces but does not support inheritance; it can contain events, variables, constants, methods, constructors, and properties.

In the following example, the struct contains two attributes:

Point
Y : Integer
X : Integer
+ <<Constructor>> New()

```
{
public struct Point
{
public int New()
{
return 0;
}
private int x;
private int y;
}
}
```

Creating a Struct

You can create a struct in any of the following ways:

- Use the Struct tool in the C# 2.0 diagram Palette.
- Select **Model > Struct Objects** to access the List of Struct Objects, and click the Add a Row tool.

- Right-click the model or package in the Browser, and select **New > Struct**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Struct Properties

Struct property sheets contains all the standard class tabs along with the C# tab, the properties of which are listed below:

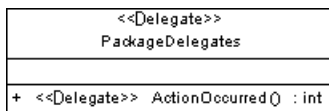

Property	Description
New	Specifies the new modifier for the struct declaration.
Unsafe	Specifies the unsafe modifier for the struct declaration.

C# 2.0 Delegates

Delegates are type-safe reference types that provide similar functions to pointers in other languages. PowerDesigner models delegates as classes with a stereotype of <<Delegate>> with a single operation code-named "<signature>". The visibility, name, comment, flags and attributes are specified on the class object whereas the return-type and parameters are specified on the operation.

A type-level (class or struct) delegate is modeled either as an operation bearing the <<Delegate>> stereotype, or as a namespace-level delegate in which the class representing the delegate is inner to the enclosing type.

For information about creating and working with classes, see *Classes (OOM)* on page 29.

```
{
  public delegate int ActionOccurred();
}
```

Creating a Delegate

You can create a delegate in any of the following ways:

- Use the Delegate tool in the C# 2.0 diagram Palette.
- Select **Model > Delegate Objects** to access the List of Delegate Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Delegate**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Delegate Properties

Delegate property sheets contains all the standard class tabs along with the C# tab, the properties of which are listed below:

Property	Description
New	Specifies the new modifier for the delegate declaration.
Unsafe	Specifies the unsafe modifier for the delegate declaration.

C# 2.0 Enums

Enums are sets of named constants. PowerDesigner models enums as classes with a stereotype of <<Enum>>.

<<enumeration>> Color
- Red : Object
- Blue : Object
- Green : Object
- Max : Object = Blue

```
{
public enum Color : colors
{
    Red,
    Blue,
    Green,
    Max = Blue
}
}
```

For information about creating and working with classes, see *Classes (OOM)* on page 29.

Creating an Enum

You can create an enum in any of the following ways:

- Use the Enum tool in the C# 2.0 diagram Palette.
- Select **Model > Enum Objects** to access the List of Enum Objects, and click the Add a Row tool.
- Right-click the model or package in the Browser, and select **New > Enum**.

For general information about creating objects, see the Objects chapter in the *Core Features Guide*.

Enum Properties

C# Enum property sheets contain all the standard class tabs along with the C# tab, the properties of which are listed below:

Property	Description
Base Integral Type	Specifies the base integral type for the enum.
New	Specifies the new modifier for the enum declaration.

C# 2.0 Fields

PowerDesigner models C# fields as standard UML attributes.

For information about creating and working with attributes, see *Attributes (OOM)* on page 65.

Field Properties

C# Field property sheets contain all the standard attribute tabs along with the C# tab, the properties of which are listed below:

Property	Description
Compilation Unit	Specifies the compilation unit in which the field will be stored. This field is only available if the parent type is a partial type (allocated to more than one compilation unit).
New	Specifies the new modifier for the field declaration.
Unsafe	Specifies the unsafe modifier for the field declaration.
Const	Specifies the const modifier for the field declaration.
ReadOnly	Specifies the readonly modifier for the field declaration.

C# 2.0 Methods

PowerDesigner models C# methods as operations.

For information about creating and working with operations, see *Operations (OOM)* on page 76.

Method Properties

Method property sheets contain all the standard operation tabs along with the C# tab, the properties of which are listed below:

Property	Description
Compilation Unit	Specifies the compilation unit in which the method will be stored. This field is only available if the parent type is a partial type (allocated to more than one compilation unit).
Extern	Specifies the extern modifier for the method declaration.
New	Specifies the new modifier for the method declaration.
Override	Specifies the override modifier for the method declaration.
Unsafe	Specifies the unsafe modifier for the method declaration.
Virtual	Specifies the virtual modifier for the method declaration.
Scope	Specifies the scope of the method.
Base Initializer	<p>Creates an instance constructor initializer of the form base, causing an instance constructor from the base class to be invoked.</p> <p>In the following example, class B inherits from class A. You define a Base Initializer in the class B constructor, which will be used to initialize the class A constructor:</p> <pre> classDiagram class A { + <<constructor>> A(int x, int y) } class B { + <<constructor>> B(int x, int y) } A < -- B </pre> <pre> internal class B : A { public B(int x, int y) : base(x + y, x - y) {} } </pre>
This Initializer	Creates an instance constructor initializer, causing an instance constructor from the class itself to be invoked.

Method Parameters

You define C# method parameters using operation parameters.

You can define the following parameter modifiers in PowerDesigner:

C# modifier	PowerDesigner equivalent
<i>[none]</i>	Select <i>In</i> in the Parameter Type box on the parameter property sheet General tab
<i>ref</i>	Select <i>In/Out</i> in the Parameter Type box on the parameter property sheet General tab
<i>out</i>	Select <i>Out</i> in the Parameter Type box on the parameter property sheet General tab
<i>params</i>	Select the <i>Variable Argument</i> checkbox on the parameter property sheet General tab

Overriding Methods Using New

When a class inherits from another class and contains methods with identical signature as in the parent class, the *New* check box is automatically selected to make the child method prevail over the parent method.

Constructors and Destructors

You design C# *constructors* and *destructors* by clicking the *AddDefault Constructor/Destructor* button in the list of operations of a class. This automatically creates a constructor with the Constructor stereotype, and a destructor with the Destructor stereotype. Both constructor and destructor are grayed out in the list, which means you cannot modify their definition.

Method Implementation

Class methods are implemented by the corresponding interface operations. To define the implementation of the methods of a class, you have to use the *To be implemented* button in the Operations tab of a class property sheet, then click the *Implement* button for each method to implement. The method is displayed with the <<*Implement*>> stereotype.

Operator Method

You design a C# *operator* using an operation with the <<*Operator*>> stereotype. Make sure the <<*Operator*>> operation has Public visibility and the Static property selected.

To define an *external operator*, you have to set the *extern extended* attribute of the operation to True. The *new*, *virtual* and *override* extended attributes are not valid for operators.

The operator *token* (like +, -, !, ~, or ++ for example) is the name of the method.

IntVector
+ <<Operator>> Oper1 (+, -) : int

Conversion Operator Method

You design a C# *conversion operator* using an operation with the <<ConversionOperator>> stereotype.

You also need to declare the conversion operator using the *explicit* or *implicit* keywords. You define the conversion operator keyword by selecting the implicit or explicit value of the *scope* extended attribute.

In the following example, class Digit contains one explicit conversion operators and one implicit conversion operator:

<<struct>> Digit	
- value	: byte
+ <<constructor>>	Digit (byte value)
+ <<ConversionOperator>>	byte (Digit d) : byte
+ <<ConversionOperator>>	Digit (byte b) : Digit

```
public struct Digit
{
    public Digit(byte value)
    {
        if (value < 0 || value > 9) throw new ArgumentException();
        this.value = value;
    }
    public static implicit operator byte(Digit d)
    {
        return d.value;
    }

    public static explicit operator Digit(byte b)
    {
        return new Digit(b);
    }
    private byte value;
}
```

C# 2.0 Events, Indexers, and Properties

PowerDesigner represents C# events, indexers, and properties as standard UML attributes with additional properties as follows:

- Events – stereotype <<Event>> with one or two linked operations representing the add and/or remove handlers
- Indexers – stereotype <<Indexer>> with one or two linked operations representing the get and/or set accessors
- Properties – stereotype <<Property>> with one or two linked operations representing the get and/or set accessors. In addition, you should note that:

- The visibility of the property is defined by the visibility of the get accessor operation if any, otherwise by that of the set accessor operation.
- When an attribute becomes a property, an implementation attribute is automatically created to store the property value. The implementation attribute is not persistent and has a private visibility. It has the stereotype <<PropertyImplementation>> and has the same name than the property but starting with a lowercase character. If the property name already starts with a lower case its first character will be converted to uppercase.
- The implementation attribute can be removed for properties not needing it. (calculated properties for instance)
- If the boolean-valued extended attribute Extern is set to true, no operations should be linked to the property.
- When a property declaration includes an extern modifier, the property is said to be an external property. Because an external property declaration provides no actual implementation, each of its accessor-declarations consists of a semicolon.

Event Example

The following example shows the Button class, which contains three events:

Button		
-	<<Event>>	Click : Object
-	<<Event>>	DoubleClick : Object
-	<<Event>>	RightClick : Object

Property Example

In the following example, class Employee contains 2 properties. The Setter operation has been removed for property TimeReport:

Employee		
-	<<Property>>	Function : int
-	<<Property>>	TimeReport : int
-	<<PropertyImplementation>>	_Function : int
-	<<PropertyImplementation>>	_TimeReport : int
+	<<Setter>>	set_Function (int value) : void
+	<<Getter>>	get_Function () : int
+	<<Getter>>	get_TimeReport () : int

```

{
public class Employee
{
private int _Function;
private int _TimeReport;
// Property Function
private int Function
{
get
{
return _Function;
}
set

```

```

    {
        if (this._Function != value)
            this._Function = value;
    }
}
// Property TimeReport
private int TimeReport
{
    get
    {
        return _TimeReport;
    }
}
}

```

Indexer Example

In the following example, class Person contains indexer attribute Item. The parameter used to sort the property is String Name:

Person	
- <<Indexer>>	Item : int
- <<IndexerImplementation>>	_childAges : Hashtable
+ <<Setter>>	set_Item (int value) : void
+ <<Getter>>	get_Item () : int

```

public class Person
{
    private Hashtable _childAges;
    // Indexer Item
    private int this[String name]
    {
        get
        {
            return (int)_ChildAges[name];
        }
        set
        {
            _ChildAges[name] = value;
        }
    }
}
Person someone;
someone ["Alice"] = 3;
someone ["Elvis"] = 5;

```

Creating an Event, Indexer, or Property

To Create an Event, Indexer, or Property:

1. Open the property sheet of a type and click the Attributes tab.
2. Click the Add button at the bottom of the tab and select the appropriate option

For general information about creating and working with attributes, see *Attributes (OOM)* on page 65.

Event, Indexer, and Property Properties

Event, indexer, and property property sheets contain all the standard attribute tabs along with the C# tab, the properties of which are listed below:

Property	Description
Compilation Unit	Specifies the compilation unit in which the attribute will be stored. This field is only available if the parent type is a partial type (allocated to more than one compilation unit).
New	Specifies the new modifier for the attribute declaration.
Unsafe	Specifies the unsafe modifier for the attribute declaration.
Abstract	Specifies the abstract modifier for the attribute declaration.
Extern	Specifies the extern modifier for the attribute declaration.
Override	Specifies the override modifier for the attribute declaration.
Sealed	Specifies the sealed modifier for the attribute declaration.
Virtual	Specifies the virtual modifier for the attribute declaration.

C# 2.0 Inheritance and Implementation

PowerDesigner models C# inheritance links between types as standard UML generalizations.

For more information about generalizations, see *Generalizations (OOM)* on page 97.

PowerDesigner models C# implementation links between types and interfaces as standard UML realizations. For more information, see *Realizations (OOM)* on page 103.

C# 2.0 Custom Attributes

PowerDesigner provides full support for C# 2.0 custom attributes, which allow you to add metadata to your code. This metadata can be accessed by post-processing tools or at run-time to vary the behavior of the system.

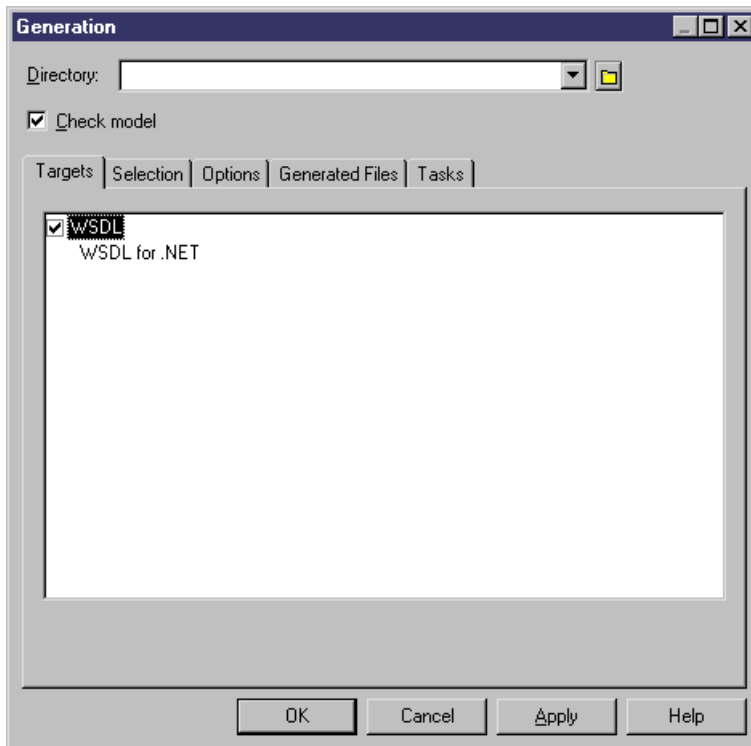

You can use built-in custom attributes, such as `System.Attribute` and `System.ObsoleteAttribute`, and also create your own custom attributes to apply to your types.

For general information about modeling this form of metadata in PowerDesigner, see *Annotations (OOM)* on page 109.

Generating C# 2.0 Code

PowerDesigner can generate C# 2.0 code.

1. Select **Language > Generate C# Code** to open the Generation dialog box:

2. Enter a directory in which to generate the files, specify whether you want to perform a model check, and select the appropriate target.
3. [optional] Click the Selection tab and specify the objects that you want to generate from. By default, all objects are generated, and PowerDesigner remembers for any subsequent generation the changes you make.
4. [optional] Click the Options tab and set any necessary generation options. For more information, see *C# Generation dialog Options tab* on page 555.
5. [optional] Click the Generated Files tab and specify which files will be generated. By default, all objects and compilation units are generated, and PowerDesigner remembers for any subsequent generation the changes you make.
6. [optional] Click the Tasks tab and specify any additional generation tasks to perform. For more information, see *C# Generation dialog Tasks tab* on page 556.

7. Click OK to begin generation.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation tab of the Output window, located in the bottom part of the main window.

All C# files are generated in the destination directory.

C# Generation Dialog Options Tab

The following options are available on this tab:

Option	Description
Generate object ids as documentation tags	Specifies whether to generate object ids for use as documentation tags.
Sort class members primarily by	Specifies the primary method by which class members are sorted. You can choose between: <ul style="list-style-type: none"> • Visibility • Type
Class members type sort	Specifies the order by which class members are sorted in terms of their type. You can choose between: <ul style="list-style-type: none"> • Methods – Properties - Fields • Properties – Methods - Fields • Fields – Properties - Methods
Class members visibility sort	Specifies the order by which class members are sorted in terms of their visibility. You can choose between: <ul style="list-style-type: none"> • Public - Private • Private – Public • None
Generate Visual Studio 2005 project files	Specifies whether to generate project files for use with Visual Studio 2005.
Generate Assembly Info File	Specifies whether to generate information files for assemblies.
Generate Visual Studio Solution File	Specifies whether to generate a solution file for use with Visual Studio 2005.
Generate Web Service C# code in .asmx file	Specifies whether to generate web services in a .asmx file.
Generate default accessors for navigable associations	Specifies whether to generate default accessors for navigable associations.

C# Generation Dialog Tasks Tab

The following tasks are available on this tab:

Task	Description
WSDLDotNet: Generate Web service proxy code	Generates the proxy class
Compile source files	Compiles the source files
Open the solution in Visual Studio	Depends on the Generate Visual Studio 2005 project files option. Opens the generated project in Visual Studio 2005.

Defining C# Environment Variables

Variables used for C# generation are defined in the General Options dialog box.

For more information on variables and general options, see "Customizing your Modeling Environment" section in the Models chapter of the *Core Features Guide*.

The following variables can be defined in the General Options dialog box:

Variable	Description
CSC	C# compiler full path. For example, C:\WINDOWS\Microsoft.NET\Framework\v1.0.3705\csc.exe
WSDL	Web Service proxy generator full path. For example, C:\Program Files\Microsoft Visual Studio .NET\FrameworkSDK\Bin\wsdl.exe

Reverse Engineering C# 2.0 Code

You can reverse engineer C# files into an OOM.

1. Select **Language > Reverse Engineer C#** to open the Reverse Engineer C# dialog box.
2. Select what form of code you want to reverse engineer. You can choose between:
 - C# files (.cs)
 - C# directories
 - C# projects (.csproj)
3. Select files, directories, or projects to reverse engineer by clicking the Add button.

Note: You can select multiple files simultaneously using the ctrl or shift keys. You cannot select multiple directories.

The selected files or directories are displayed in the dialog box and the base directory is set to their parent directory. You can change the base directory using the buttons to the right of the field.

4. [optional] Click the Options tab and set any appropriate options. For more information, see *C# Reverse Engineer dialog Options tab* on page 557.
5. [optional] Click the Preprocessing tab and set any appropriate preprocessing symbols. For more information, see *C# reverse engineering preprocessing directives* on page 558.
6. Click OK to begin the reverse engineering.

A progress box is displayed. If the model in which you are reverse engineering already contains data, the Merge Models dialog box is displayed.

For more information on merging models, see the Comparing and Merging Models chapter in the *Core Features Guide*.

The classes are added to your model. They are visible in the diagram and in the Browser, and are also listed in the Reverse tab of the Output window, located in the lower part of the main window.

C# Reverse Engineer Dialog Options Tab

The following options are available on this tab:

Option	Description
File encoding	Specifies the default file encoding of the files to reverse engineer
Ignore operation body	Reverses classes without including the body of the code
Ignore comments	Reverses classes without including code comments
Create Associations from classifier-typed attributes	Creates associations between classes and/or interfaces
Create symbols	Creates a symbol for each object in the diagram, if not, reversed objects are only visible in the browser

Option	Description
Libraries	<p>Specifies a list of library models to be used as references during reverse engineering.</p> <p>The reverse engineered model may contain shortcuts to objects defined in a library. If you specify the library here, the link between the shortcut and its target object (in the library) will be preserved and the library will be added to the list of target models in the reverse engineered model.</p> <p>You can drag and drop the libraries in the list in order to specify a hierarchy among them. PowerDesigner will seek to resolve shortcuts found in the reverse engineered model against each of the specified libraries in turn. Thus, if library v1.1 is displayed in the list above library v1.0, PowerDesigner will first attempt to resolve shortcuts against library v1.1 and will only parse library v1.0 if unresolved shortcuts remain.</p> <p>You should use the List of Target Models to manage libraries related to the reverse engineered model, for example, you can change the library version. See the "Working with the target models referenced by the model" section in the Shortcuts and Object Replications chapter of the <i>Core Features Guide</i>.</p>
Preserve file structure	Creates an artifact during reverse engineering in order to be able to regenerate an identical file structure
Mark classifiers not to be generated	Specifies that reversed classifiers (classes and interfaces) will not be generated from the model. To generate the classifier, you must select the Generate check box in its property sheet

C# Reverse Engineering Preprocessing Directives

C# files may contain conditional code that needs to be handled by *preprocessing directives* during reverse engineering. A preprocessing directive is a command placed within the source code that directs the compiler to do a certain thing before the rest of the source code is parsed and compiled. The preprocessing directive has the following structure:

```
#directive symbol
```

Where *#* is followed by the name of the directive, and *symbol* is a conditional compiler constant used to select particular sections of code and exclude other sections.

In C#, symbols have no value, they can be true or false.

In the following example, the *#if* directive is used with symbol *DEBUG* to output a certain message when *DEBUG* symbol is true, if *DEBUG* symbol is false, another output message is displayed.

```
using System;
public class MyClass
{
    public static void Main()
```

```

{
    #if DEBUG
        Console.WriteLine("DEBUG version");
    #else
        Console.WriteLine("RELEASE version");
    #endif
}
}

```

You can declare a list of symbols for preprocessing directives. These symbols are parsed by preprocessing directives: if the directive condition is true the statement is kept, otherwise the statement is removed.

C# Supported Preprocessing Directives

The following directives are supported during preprocessing:

Directive	Description
#define	Defines a symbol
#undefine	Removes a previous definition of the symbol
#if	Evaluates a condition, if the condition is true, the statement following the condition is kept otherwise it is ignored
#elif	Used with the #if directive, if the previous #if test fails, #elif includes or exclude source code, depending on the resulting value of its own expression or identifier
#endif	Closes the #if conditional block of code
#warning	Displays a warning message if the condition is true
#error	Displays an error message if the condition is true

Note: #region, #endregion, and #line directives are removed from source code.

Defining a C# Preprocessing Symbol

You can define C# preprocessing symbols in the preprocessing tab of the reverse engineering dialog box.

Symbol names are case sensitive and must be unique. Make sure you do not type reserved words like true, false, if, do and so on.

The list of symbols is saved in the model and will be reused when you synchronize your model with existing code using the Synchronize with Generated Files command.

For more information on the synchronize with generated files command see *Synchronizing a Model with Generated Files* on page 282.

You can use the Set As Default button to save the list of symbols in the registry.

1. Select **Language > Reverse engineering C#**.

CHAPTER 21 Working with XML

You can model XML schemas, DTDs and XDR files in an OOM. PowerDesigner also provides the XML Schema Model (XSM), a dedicated XML modeling environment (see the *XML Modeling* guide).

Designing for XML

This section explains how to design XML Schema objects in the PowerDesigner Object Oriented Model.

XML Object	Modeling in PowerDesigner
Schema	Any package or model can generate an XML Schema. You do not need to define specific attribute or stereotype for the package or model to generate an XML Schema.
Complex type	<p>In XML Schema, a complex type allows elements in its content and may carry attributes. Complex types can be:</p> <ul style="list-style-type: none">• Global, that is to say defined as a child of the schema element, in order to be reused among schema elements. You design a global complex type using a class with the <<complexType>> stereotype. In the following example, UsAddress is a complex type with a set of attributes that specify it: <pre><xsd:complexType name="UsAddress"> <xsd:element name="name" type="Name"/> <xsd:element name="street" type="string"/> <xsd:element name="town" type="string"/> <xsd:element name="zip" type="Integer"/> </xsd:complexType></pre>• Local to an element definition. In this case, you have to create a class with the <<element>> stereotype. You then need to set the isComplexType extended attribute of the class to True. This is to make sure that attributes defined in the <<element>> class are generated as a complex type: <pre><xsd:element name="customer"> <xsd:complexType> <xsd:element name="name" type="int"/> <xsd:element name="address" type="int"/> </xsd:complexType> </xsd:element></pre>

XML Object	Modeling in PowerDesigner
Simple type	<p>In XML Schema, a simple type can be a string or a decimal built into XML Schema, it can also be a type derived from those built-in the language. A simple type cannot contain elements or attributes. In PowerDesigner, you design a simple type using a class with the <<simpleType>> stereotype. You must add an attribute with the <<simpleType>> stereotype to this class.</p> <pre data-bbox="440 369 919 470"> <xsd:simpleType name="string"> <xsd:restriction base="string"> </xsd:restriction> </xsd:simpleType> </pre>
Deriving types	<p>XML Schema allows you to derive new types by extending or restricting an existing type. In PowerDesigner, you design the extension mechanism using a generalization between two classes. The contentDerivation extended attribute of the generalization allows you to set the type of derivation: extension or restriction.</p> <p>To design type derivation from a basic type (defined in Settings\DataTypes\BasicDataTypes in the object language editor) you cannot use classes and generalizations, you have to use the simpleContentBase and simpleContentDerivation extended attributes. For example, class A derives from basic data type xsd:string. You define this derivation setting the following values for class A:</p>
Union	<p>A <<union>> class generates a <<union>> attribute and is migrated to specify the attribute location. You can generate single line <union> tag as follows: <union memberTypes="{member types list}"/>. You can define a value for the extended attribute memberTypes used with simple Type attributes (either <<simpleType>> or <<simpleAttribute>>).</p>
Global element	<p>A global element is declared as a child of the schema element; it can be referenced in one or more declarations. You define an XML Schema global element using a class with the <<element>> stereotype in PowerDesigner. You define the type of a global element using the following methods:</p> <ul data-bbox="440 1154 1184 1432" style="list-style-type: none"> • For a complex type, use attributes. In this case you have to set the isComplexType extended attribute to True for attributes defined in the <<element>> class to be generated as a complex type: <pre data-bbox="481 1251 1056 1399"> <xsd:element name="customer"> <xsd:complexType> <xsd:element name="name" type="int"/> <xsd:element name="address" type="int"/> </xsd:complexType> </xsd:element> </pre> • For a simple type, set a value for the type extended attribute <pre data-bbox="481 1446 1173 1494"> <xsd:element name="Customer" type="CustomerList-Type"/> </pre>

XML Object	Modeling in PowerDesigner
Element group	<p>An element group is declared as a child of the schema element; it can be referenced in one or more declarations using the <<ref>> stereotype on an association. You define an XML Schema element group using a class with the <<group>> stereotype in PowerDesigner.</p>
Attribute group	<p>An attribute group is a set of attributes. You define an XML Schema attribute group using a class with the <<attributeGroup>> stereotype in PowerDesigner. All the attributes of this class should have the <<attribute>> stereotype. For example, the following attribute group called item gathers information about an item in a purchase order:</p> <pre data-bbox="440 499 1150 626"> <xsd:attributeGroup name="item"> <xsd:attribute name="weight" type="Integer"/> <xsd:attribute name="shipping_method" type="Integer"/> </xsd:attributeGroup> </pre>
Reference	<p>A reference is a simplified declaration of an element or an attribute group referencing a global definition. In PowerDesigner, you design a reference using an association with the <<ref>> stereotype. In the following example, element Customer references complex type UsAddress.</p> <pre data-bbox="440 782 1103 986"> <xsd:element name="Customer"> <xsd:complexType> <xsd:element name="name" type="int"/> <xsd:element name="ID" type="int"/> <xsd:complexType ref="UsAddress" minOccurs="0" maxOccurs="unbounded"/> </xsd:complexType> </xsd:element> </pre> <p>Note that the referenced element is introduced by its stereotype. In the above example, UsAddress is of <<complexType>> and complexType is displayed in the reference line: <xsd:complexType ref="UsAddress" minOccurs="0" maxOccurs="unbounded"/></p>

XML Object	Modeling in PowerDesigner
Sequence	<p>XML Schema elements can be constrained to appear in the same order as they are declared, this is called a sequence. In PowerDesigner, depending on the type of sequence you need to design, you can use one of the following methods:</p> <ul style="list-style-type: none"> • If all the class attributes are defined in the sequence, you should create a class without stereotype and set the class extended attribute <code>isSequence</code> to true. In the following example, all attributes of class <code>item_sequence</code> are defined in the sequence: <pre data-bbox="481 447 1089 621"> <xsd:element name="item_sequence"> <xsd:sequence> <xsd:element name="prodName" type="int" /> <xsd:element name="prodID" type="int" /> <xsd:element name="prodPrice" type="int" /> </xsd:sequence> </xsd:element> </pre> • If some of the class attributes do not belong to the sequence, you have to design the following construct: create a class containing the attributes belonging to the sequence and assign the <code><<sequence>></code> stereotype to this class. Create another class containing the other attributes. Select the Inner link tool in the palette and draw a link from the second class to the <code><<sequence>></code> class. The resulting code is the following: <pre data-bbox="481 812 1042 986"> <xsd:element name="PurchaseOrder"> <xsd:sequence> <xsd:element name="shipTo" type="int" /> <xsd:element name="billTo" type="int" /> </xsd:sequence> <xsd:element name="prodID" type="int" /> </xsd:element> </pre> <p>By default, inner classes are generated before attributes in a class (as defined in the Class\Template\body entry in the object language definition file). However, you can modify generation order among class attributes using the attribute migration feature. To do so, you should create an association from the parent class to the <code><<sequence>></code> class, right-click the association and select Migrate > Migrate Navigable Roles. The migrated attribute can then be moved in the list of class attributes in order to have the desired generation order.</p> <pre data-bbox="440 1222 1005 1395"> <xsd:element name="PurchaseOrder"> <xsd:element name="prodID" type="int" /> <xsd:sequence> <xsd:element name="shipTo" type="int" /> <xsd:element name="billTo" type="int" /> </xsd:sequence> </xsd:element> </pre>

XML Object	Modeling in PowerDesigner
Choice & All	<p>A choice allows you to display only one child in an instance of an element. All allows you to display all the elements in the group once or not at all. In PowerDesigner, you design a choice/all mostly as a sequence.</p> <ul style="list-style-type: none"> If all the class attributes are defined in the choice/all, you should create a class without stereotype and set the class extended attribute isChoice/isAll to true. In the following example, all attributes of class InternationalShipping are defined in the choice: <pre data-bbox="481 447 1158 621"> <xsd:element name="InternationalShipping"> <xsd:choice> <xsd:element name="EuropeShipping" type="int"/> <xsd:element name="AfricaShipping" type="int"/> <xsd:element name="AsiaShipping" type="int"/> </xsd:choice> </xsd:element> </pre> If some of the class attributes do not belong to the choice, you have to create a class containing the attributes belonging to the choice and assign the <<choice>>/<<all>> stereotype to this class. Create another class containing the other attributes. Select the Inner link tool in the palette and draw a link from the second class to the <<choice>>>/<<all>> class: You can also use the attribute migration feature to modify generation order among attributes (see Sequence, above).

Generating for XML

When you generate XML from an OOM, PowerDesigner creates one XML file per package. The file contains the definition of each of the classes you select to generate in the Generation dialog box. You can select any of the classes from the model, including those that are contained within packages or sub-packages.

- XML Schema - a .XSD file will be generated per package or model. You can generate an XML Schema definition in this specific format for validations and/or data exchange purposes
- XML DTD - a .DTD file will be generated per package or model. A DTD file provides an overall structure for an XML file. You can generate an XML DTD definition in this specific format for validations and/or data exchange purposes

Navigable associations are migrated and generated as attributes although they do have their own definition in the object language file. Interfaces, operations, and links (dependencies, realizations and generalizations) are not included in the generated file.

To change the XML format type, you must change the object language for the model (by selecting **Language > Change Current Object Language**). You can create a new XML object language based on an existing one if you want to generate in another type of XML format that is not available in PowerDesigner.

The files generated are generated with the .xsd, .dtd or .xdr extension depending on the XML format specified. A generation log file is also created after generation.

1. Select **Language > Generate XML-language Code** to open the Generation dialog box.
2. Enter a destination directory for the generated files and, optionally, select the Check Model checkbox to verify the validity of your model before generation.
3. Click the Selection tab and select the objects to include in the generation from the various sub-tabs.
4. Click OK to generate XML files in the specified directory.

Reverse-Engineering XML

You can reverse engineer *.DTD, *.XSD, and *.XML files into an OOM. You can right-click the files to reverse engineer and select the Edit command to view the content of your files. To use this command you have to associate the file extension with an editor in the General Options/Editor dialog box.

When you reverse engineer a DTD file into an OOM, you get a more readable view of the DTD. This feature can be very helpful when you want to check and understand a new DTD that you have not generated. When you reverse engineer a DTD file into an OOM:

- Referenced DTD files, using DOCTYPE keyword, may not be reversed correctly, it is therefore better to choose a real DTD file rather than an XML document referencing a DTD file with a DOCTYPE document type declaration
- Elements of type #PCDATA are reversed as attributes
- An element that has both a parent and a child element is linked to its parent element by an aggregation link
- If an empty element has no child object but has attributes, it is reversed as a class and its attributes become attributes of the class
- Attributes of type ID and IDREF(S) are reversed as attributes with ID and IDREF(S) data types
- The attribute sequence order may not be preserved
- Attribute groups structure is not preserved
- DTD files may not be reversed properly if they contain some reference to an undefined parameter entity

When you reverse engineer an XML Schema file into an OOM, the sequence order of the contents of an element may not be preserved and the following main elements are not reverse engineered:

- Namespace
- Key/keyref
- Field/selector

- Unique
 1. Select **Language > Reverse Engineer XML** to open the Reverse XML dialog box.
 2. Click the Add button in the Selection page, select the .xsd, .xdr or .dtd files you want to reverse, and click Open. You can select multiple files with the CTRL or SHIFT keys. The Reverse XML dialog box displays the files you selected.
 3. Click OK to reverse the files. If the model to which you are reverse engineering already contains objects, the Merge Models dialog box is displayed. For more information on merging models, see the Comparing and Merging Models chapter in the Core Features Guide.

The classes are added to your model and are visible in the diagram and in the Browser.

CHAPTER 22 Working with C++

PowerDesigner supports the modeling of C++ programs including round-trip engineering.

Designing for C++

This section explains how to design C++ objects in the PowerDesigner Object Oriented Model.

Namespace Declaration for Classifiers

The extended attribute *UseNamespace* allows you to generate a classifier inside a namespace declaration. You should set the extended attribute value to True.

Bidirectional Associations Management

The problem of bidirectional associations is addressed by using forward declarations instead of includes.

Consider a bidirection association between ClassA and ClassB.

The generated code in A.h would be the following:

```
#if !defined(__A_h)
#define __A_h

class B; // forward declaration of class B

class A
{
public:
    B* b;

protected:
private:

};

#endif
```

The generated code in B.h would be the following:

```
#if !defined(__B_h)
#define __B_h
```

```

class A; // forward declaration of class A

class B
{
public:
    A* a;

protected:
private:

};

#endif

```

This approach will not work if one of the classes is an inner class because it is not possible to forward-declare inner classes in C++.

If such a situation occurs, a warning message is displayed during generation, and the corresponding code is commented out.

Unsupported ANSI Features

PowerDesigner does not support the following C++ features:

- Templates
- Enums
- Typedefs
- Inline methods

Generating for C++

When generating with C++, the files generated are generated for classes and interfaces.

A header file with the .h extension, and a source file with the .cpp extension are generated per classifier.

A generation log file is also created after generation.

1. Select **Language > Generate C++ Code** to display the Generation dialog box.
2. Type a destination directory for the generated file in the Directory box.

or

Click the Select a Path button to the right of the Directory box and browse to select a directory path.

3. Select the objects to include in the generation from the tabbed pages at the bottom of the Selection page.

Note: All classes of the model, including those grouped into packages, are selected and displayed by default. You use the Select tools to the right of the Folder Selection list to modify the selection. The Include Sub-Packages tool allows you to include all classes located within packages.

4. Click the Options tab to display the Options page.
5. <optional> Select the Check Model check box if you want to verify the validity of your model before generation.
6. Select a value for each required option.
7. Click the Tasks tab, then select the required task(s).
8. Click OK to generate.

A Progress box is displayed. The Result list displays the files that you can edit. The result is also displayed in the Generation page of the Output window, located in the bottom part of the main window.

All C++ files are generated in the destination directory.

CHAPTER 23 Object/Relational (O/R) Mapping

PowerDesigner supports and can automatically generate and synchronize O/R Mappings between OOM and PDM objects.

The following table lists object mappings in these two model types:

OOM Element	PDM Element
Domain	Domain
Class (if the Persistent checkbox and Generate table option are selected)	Table
Attribute Column (if the Persistent checkbox is selected)	Column
Identifier	Identifier
Association	Reference or table
Association class	Table with two associations between the end points of the association class
Generalization	Reference

You can define mappings between these two model types in any of the following ways:

- Top-down – generate tables and other PDM objects from OOM classes
- Bottom-up – generate classes and other OOM objects from PDM tables
- Meet-in-the-middle – manually define mappings between classes and tables using the visual mapping editor

Top-Down: Mapping Classes to Tables

PowerDesigner provides default transformation rules for generating physical data models from object-oriented models. You can customize these rules with persistence settings and generation options.

1. Create your OOM, and populate it with persistent classes (see *Entity Class Transformation* on page 575), inheritance links and associations etc, to define the structure of your model domain.
2. Select **Tools > Generate Physical Data Model** to open the PDM Generation Options dialog.

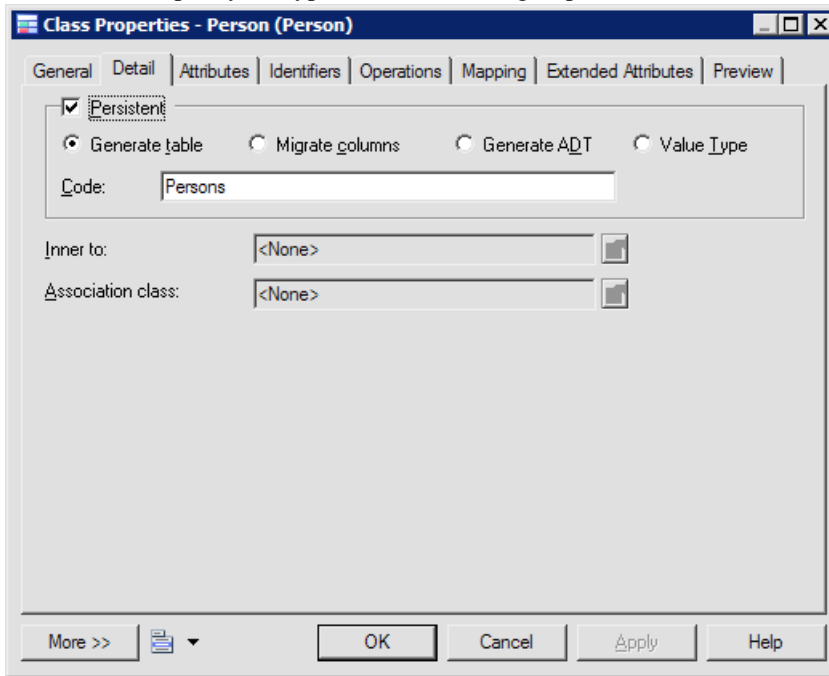

3. On the General tab, specify the DBMS type and the name and code of the PDM to generate (or select an existing PDM to update).
4. Click the Detail tab and select the O/R Mapping checkbox. You can optionally also specify a table prefix that will be applied to all generated tables.

5. Click the Selection tab and select the OOM objects that you want to transform into PDM objects.
6. Click OK to generate (or update) your PDM.

Entity Class Transformation

To transform a class into a table, select the Persistent option on the Detail tab of its property sheet and then specify the type in the Persistent groupbox.

Persistent classes are classes with one of the following persistent types:

- **Generate table** - These classes are called Entity classes, and will be generated as separate tables. You can customize the code of the generated tables in the Code box in the Persistent groupbox. Only one table can be generated for each entity class with this type, but you can manually map an entity class to multiple tables (see *Defining entity class mapping* on page 586).
- **Migrate columns** - These classes are called Entity classes, but no separate table will be generated for them. This persistent type is used in inheritance transformation, and its attributes and associations are migrated to the generated parent or child table.
- **Generate ADT** - These classes are generated as abstract data types, user-defined data types that can encapsulate a range of data values and functions. This option is not used when you define O/R Mapping.
- **Value Type** - These classes are called Value type classes. No separate table will be generated for the class; its persistent attributes will be transformed into columns that are embedded in other table(s)

Note: Identifiers of persistent classes, where the generation type is not set to Value type are transformed into table keys. Primary identifiers are transformed into primary keys or part of

primary keys (see *Defining primary identifier mapping* on page 590). Persistent attributes contained in primary identifiers are transformed into columns of primary keys.

Attribute Transformation

To transform an attribute into a column, select the Persistent option on the Detail tab of its property sheet.

The screenshot shows the 'Attribute Properties - name (name)' dialog box with the 'Detail' tab selected. The 'Persistent' checkbox is checked. The 'Data type' is set to 'VA50' and the 'Length' is set to '50'. Other fields include 'Initial value', 'Changeability' (Changeable), 'Domain' (<None>), 'Migrated from' (<None>), and 'Primary identifier' (unchecked). The bottom of the dialog has buttons for '<< Less', 'OK', 'Cancel', 'Apply', and 'Help'.

Persistent attributes can have simple data types or complex data types:

- Simple Data Type - such as int, float, String, Date etc.
Each persistent attribute is transformed into one column. Its data type is converted into an internal standard data type, which is then mapped to the appropriate data type in the DBMS. These transformations are controlled by the table of values in the AMCDDataType entry in the Data Type folder of the DBMS definition:

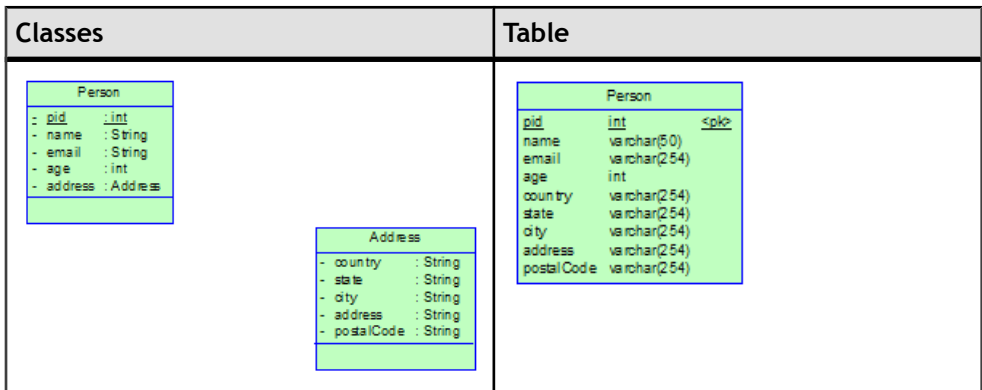

- Complex Data Type - based on a classifier. The transformation depends on the persistent settings of the classifier. The classifier is generally used as a value type class (see *Value type transformation* on page 577).

You can also customize the code of the generated data types in the Code box of the Persistent groupbox. You can also customize the code of the generated columns.

Value Type Transformation

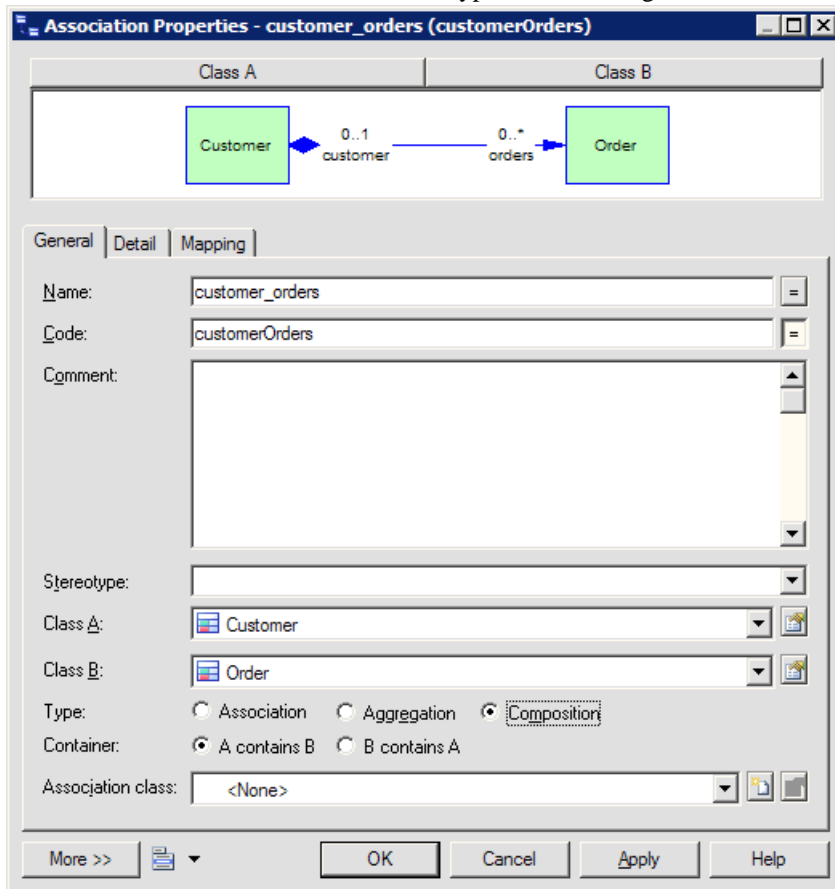

PowerDesigner supports fine-grained persistence model. Multiple classes can be transformed into single table.

Given two classes, *Person* and *Address*, where the class *Person* contains an attribute *address* whose data type is *Address*, the classes can be transformed into one table if the transformation type of Class *Address* is set to Value type. The columns transformed from persistent attributes of the class *Address* will be embedded in the table transformed from the class *Person*.

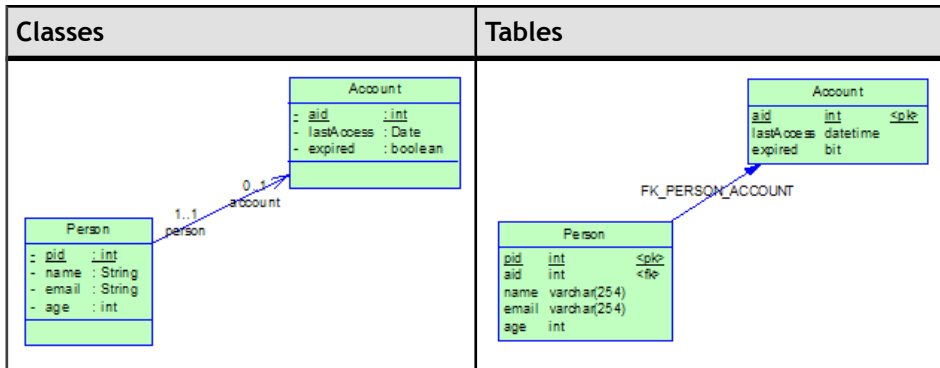

Association Transformation

Association defined between entity classes will be transformed into reference keys or reference tables. Associations with Value type classes as target or source will be ignored.

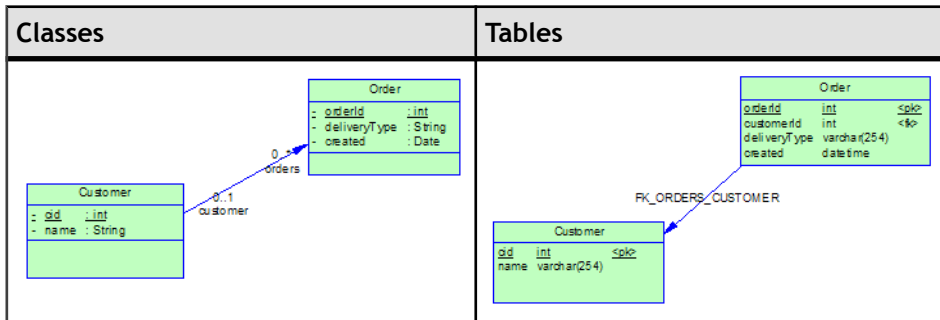

Transformation rules differ according to the type of the association:

- One-to-one - one foreign key will be generated with the same direction as the association. The primary key of parent table will also migrate into child table as its foreign key.

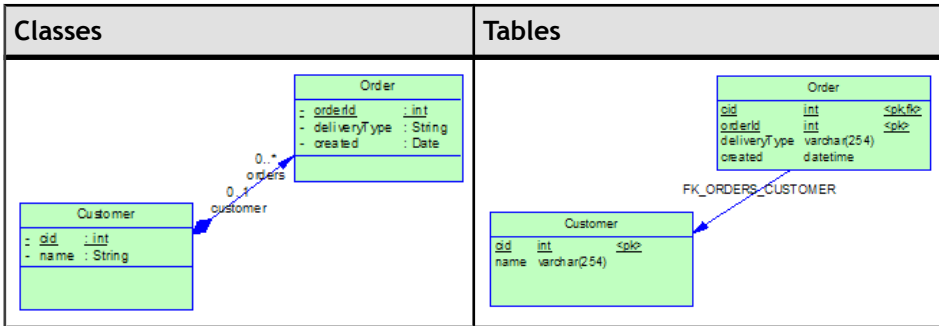

The generated foreign key has the same direction as the association direction. If the association is bidirectional (can navigate in two ways), foreign keys with both directions will be generated since PowerDesigner does not know which table is the parent table. You need to delete one manually.

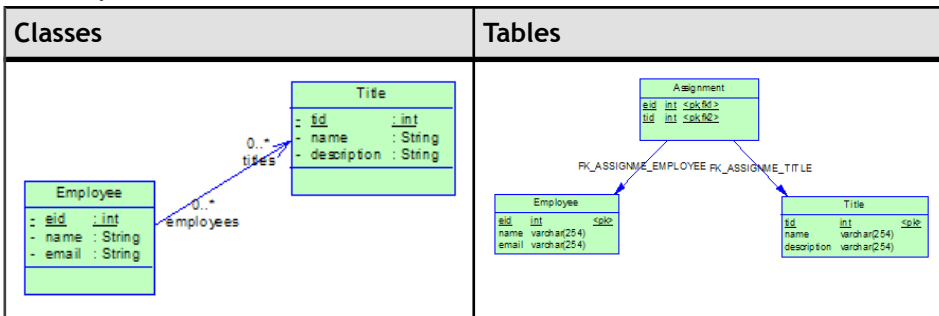

- One-to-many association - just one foreign key will be generated for each one-to-many association, whatever its direction (bidirectional or unidirectional). The reference key navigates from the table generated from the entity class on multiple-valued side to the table generated from the entity class on single-valued side.

- One-to-many composition - PowerDesigner can generate a primary key of a parent table as part of the primary key of the child table if you define the association as composition with the class on single-valued side containing the class on multiple-valued side:

- Many-to-many - each many-to-many association will be transformed into one middle table and two reference keys that navigate from the middle table to the tables generated from the two entity classes.

For most O/R Mapping frameworks, one unidirectional one-to-many association will usually be mapped to a middle table and two references navigating from the middle table to the tables mapped by the two entity classes.

For more information, see *One-to-Many Association Mapping* on page 595.

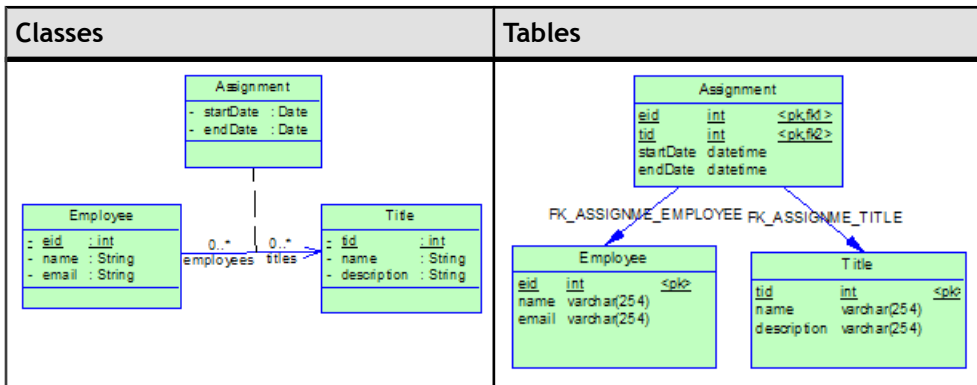

Note: The minimal multiplicity of association ends can affect the Mandatory property of the generated reference keys:

- For one-to-one associations if the minimal multiplicity of side that is transformed to parent table is more than one, the generated foreign key will be mandatory.
- For one-to-many associations, if the minimal multiplicity on single-valued side is more than one, the generated foreign key will be mandatory.

Association Class Transformation

In O/R Mapping, association classes are only meaningful for many-to-many associations. Persistent attributes in the association entity class will be transformed into columns of the middle table.

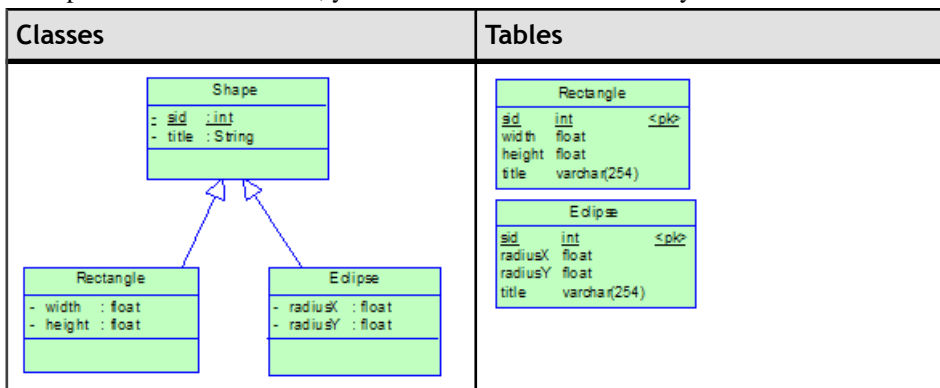

In the following example, we have defined an association class to hold extra information for the association:

Inheritance Transformation

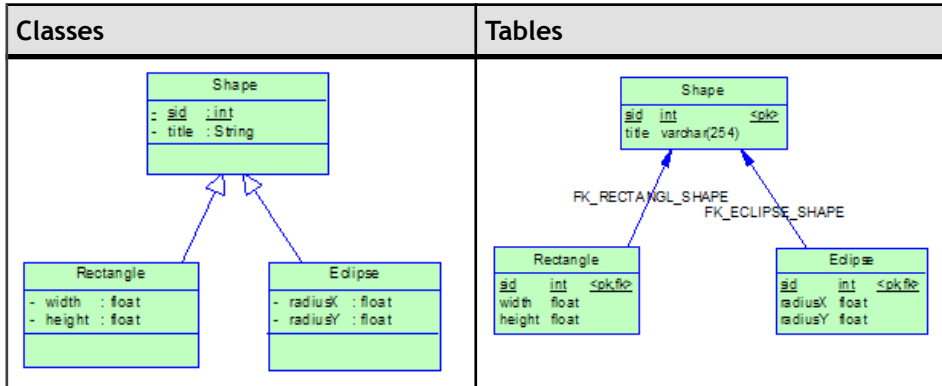

PowerDesigner supports various mapping strategies for inheritance persistence. Each strategy has its pros and cons, and you should select the most appropriate one for your needs. You can also apply mixed strategies, but this may not be well supported by your persistence framework.

- Table per class hierarchy. All the classes in a hierarchy are mapped to a single table. The table has a column that serves as a "discriminator column". The value of this column identifies the specific subclass to which the instance that is represented by the row belongs. In order to apply this kind of strategy, you should set the transformation type of leaf classes to *Generate table* and the transformation type of the other classes in the hierarchy to *Migrate columns*. PowerDesigner will only generate the tables for leaf classes. If you want to map other classes to tables, you need to create them manually.

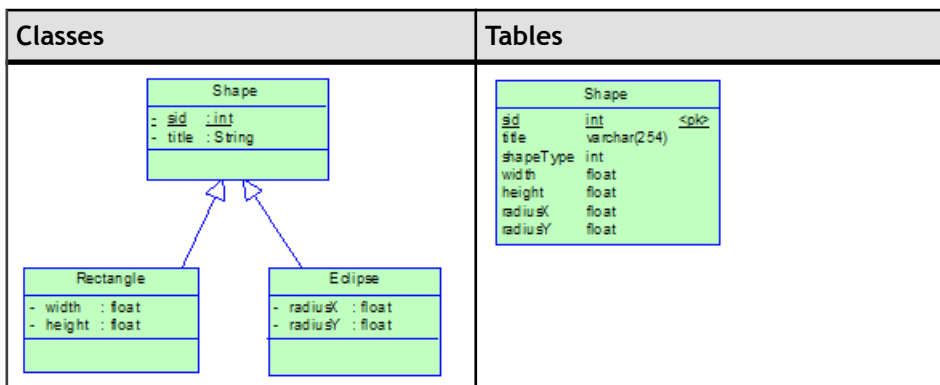

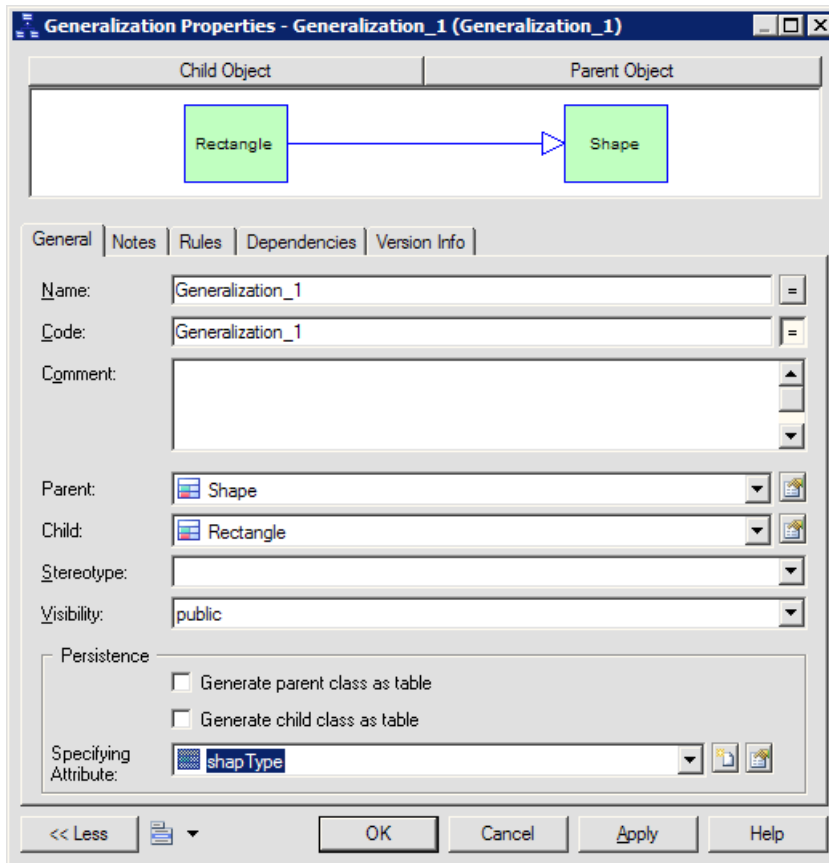

- Joined subclass. The root class of the class hierarchy is represented by a single table. Each subclass is represented by a separate table. This table contains the fields that are specific to the subclass (not inherited from its super class), as well as the column(s) that represent its primary key. The primary key column(s) of the subclass table serves as a foreign key to the primary key of the super class table.

In order to apply this kind of strategy, you should set the transformation type of all the classes to *Generate table*. You can also, optionally, define a discriminator.

- Table per class. Each class is mapped to a separate table. All properties of the class, including inherited properties, are mapped to columns of the table for the class. In order to apply this kind of strategy, you should set the transformation type of the root class to *Generate table* and the transformation type of other classes in the class hierarchy to *Migrate columns*.

For each class hierarchy, a discriminator is needed to distinguish between different class instances. You need to select one of the attributes of the root class in the *Specifying Attribute* list located in the property sheet of one of the children inheritance links of the root class. The attribute will be transformed into a discriminator column. In the following example, we define one extra attribute *shapeType* in *Shape* and select it as discriminator attribute:

- **Mixed Strategy** - You can apply more than one strategy in the same inheritance hierarchy. The transformation of entity classes with the *Generate table* transformation type will not change, but the transformation of those set to *Migrate columns* will be slightly different. If entity classes set to *Migrate columns* have both their super-class and sub-classes set to

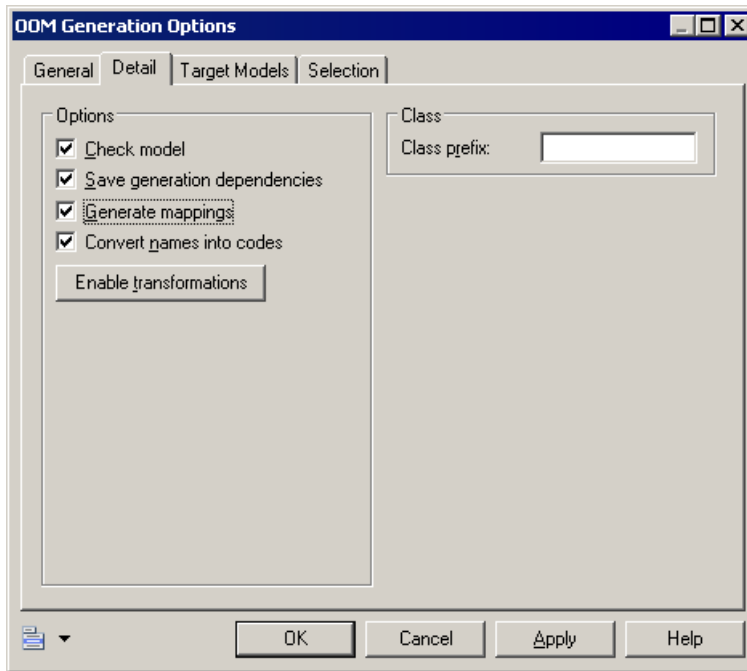

Generate table, the columns transformed from their persistent attributes will be migrated into tables transformed from sub-classes. The migration to sub-classes has higher priority.

Bottom-Up: Mapping Tables to Classes

PowerDesigner provides default transformation rules for generating object-oriented models from physical data models. You can enhance the generated mappings manually using the Mapping Editor.

When you generate an object-oriented model from a data model:

- Each selected table is transformed into a persistent entity class and its:
 - Columns are transformed into persistent attributes.
 - Keys are transformed into identifiers.
 - Primary keys are transformed into primary identifiers.
 - Reference keys have, by default, a cardinality of 0..* and will be transformed into bidirectional many-to-many associations. To generate a one-to-one association, you need to set the maximum cardinality to 1 (cardinality 0..1 or 1..1). If the reference key is mandatory, the minimal multiplicity of one side of the generated association will be 1. You cannot generate inheritance links from reference keys and tables.
1. Create your PDM (perhaps by reverse-engineering a database) and populate it with the appropriate tables and references.
 2. Select **Tools > Generate Object-Oriented Model** to open the OOM Generation Options dialog.
 3. On the General tab, specify the Object language type and the name and code of the OOM to generate (or select an existing OOM to update).
 4. Click the Detail tab and select the Generate Mappings checkbox. You can optionally also specify a class prefix that will be applied to all generated classes.

5. Click the Selection tab and select the tables that you want to transform into classes.
6. Click OK to generate (or update) your OOM.

Meet in the Middle: Manually Mapping Classes to Tables

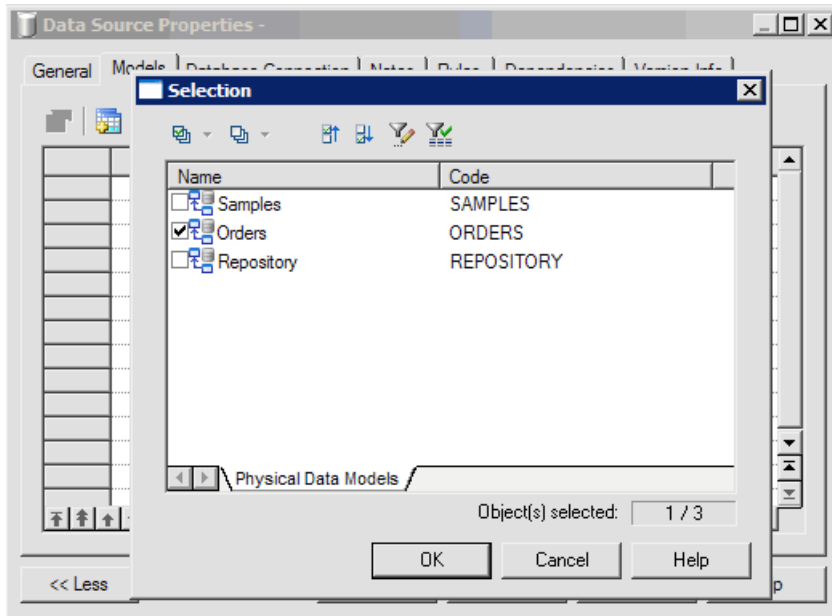

If you have an existing OOM and PDM, you can define mappings between them manually using the Mapping Editor. The O/R Mapping models in PowerDesigner are platform independent.

There are no constraints on the way you map your persistent classes. However, there are some well-defined mapping strategies, which are supported by most of O/R Mapping technologies. You should follow these strategies in order to build correct O/R Mapping models. However, minor differences still reside between them which we will raise when necessary.

Note: when your O/R Mapping models are related with a specific technology, for example when you add an EJB 3.0 persistence extended model definition to your model, there will be some constraints and we provide model checks to help you check the syntax of the mappings you have defined.

In order to define basic mapping, you have to define a data source for your OOM. Then you can define the mapping using the Mapping tab of the OOM object you want to map to a PDM object or using the Mapping Editor.

1. In the OOM, select **Model > Data Sources** to open the corresponding list.
2. Click the Add a row tool to create a data source.
You can create multiple data sources in the model.
3. Double-click the data source in the list to open its property sheet.
4. On the Models tab, click the Add Models tool to select one or more PDMs from the available open PDM as source models for the data source.

5. Define mappings using the Mapping tab or the Mapping Editor.

The Mapping Editor is more convenient to use as you can define all the mappings in one place just by some drag and drop actions. However, it is easy to understand the correspondence between OOM elements and PDM elements by using the Mapping tab in objects property sheet. So we will introduce you how to use Mapping definition tab to define mappings in the following sections.

When you are familiar with O/R Mapping concepts, you can use the Mapping Editor.

Entity Class Mapping

In order to define mapping for entity classes, you have to:

- Open the Mapping tab of a class property sheet
- Click the Create Mapping to create a new class mapping
- In the Select an object dialog box, add a data model element as mapping source

You can also click the Add objects tool in the Class Sources sub-tab of the Mapping tab after you created the class mapping.

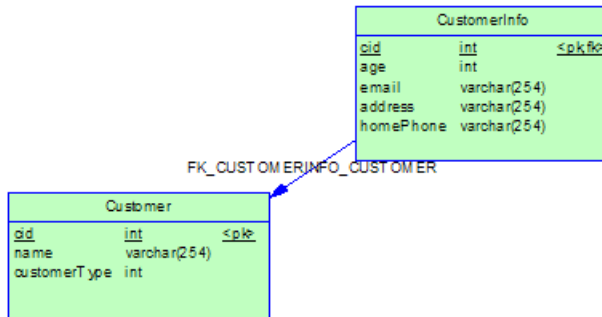

You can add tables, views and references as mapping sources. There are some constraints on views as mapping sources, as some views cannot be updated. When you add references as mapping sources, tables at the two ends will also be added.

You can add multiple tables as mapping sources. Usually, the first table you add is called the primary table. Other tables are called secondary tables. Each secondary table should have reference key referring to primary table, which is joined on its primary key.

Given the following class *Customer*:

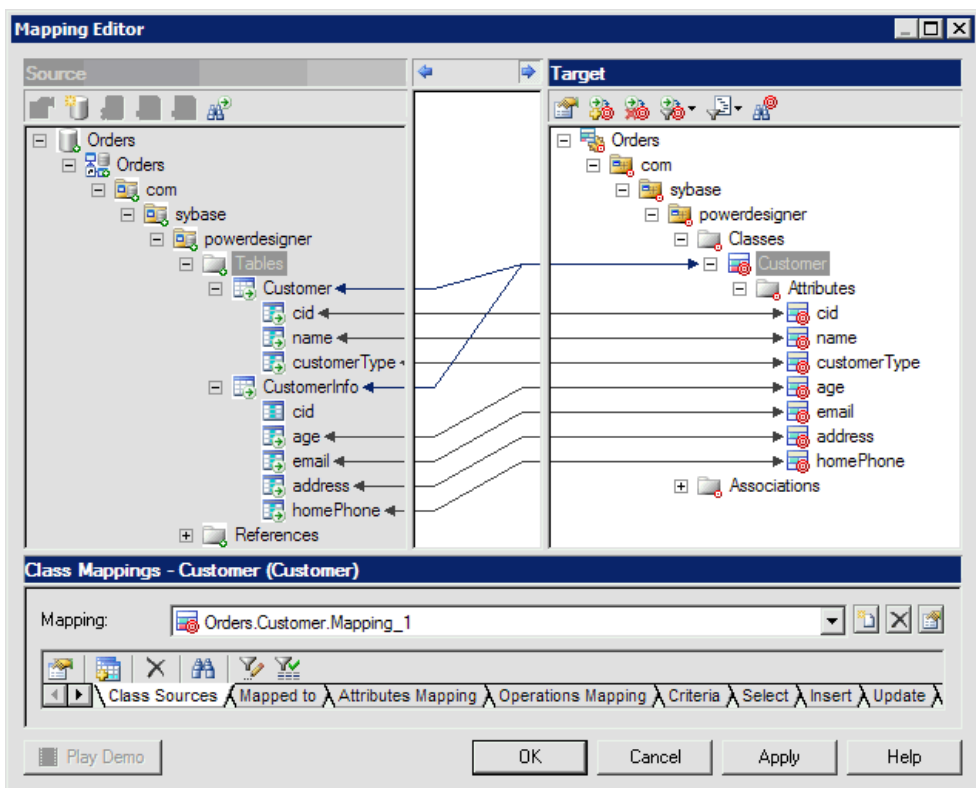

Customer	
- id	: int
- name	: String
- customerType	: int
- age	: int
- email	: String
- address	: String
- homePhone	: String

It can be mapped to two tables:

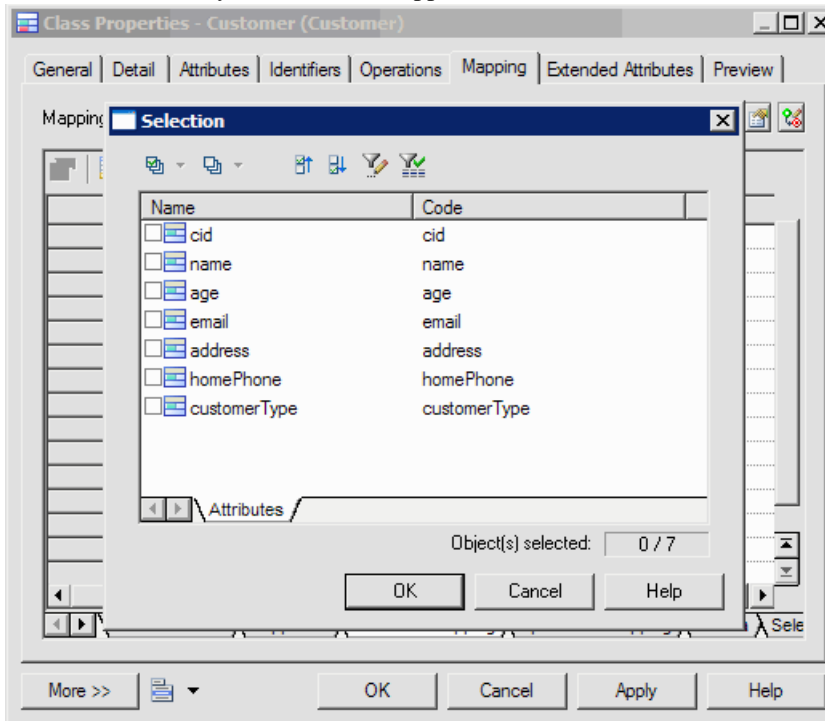

The *Customer* table is the primary table. The *CustomerInfo* table is the secondary table and it has one reference key referring to the primary table, which is joined on its primary key.

With the Mapping Editor, you just have to drag the two tables and drop them to class *Customer* to define class mappings.

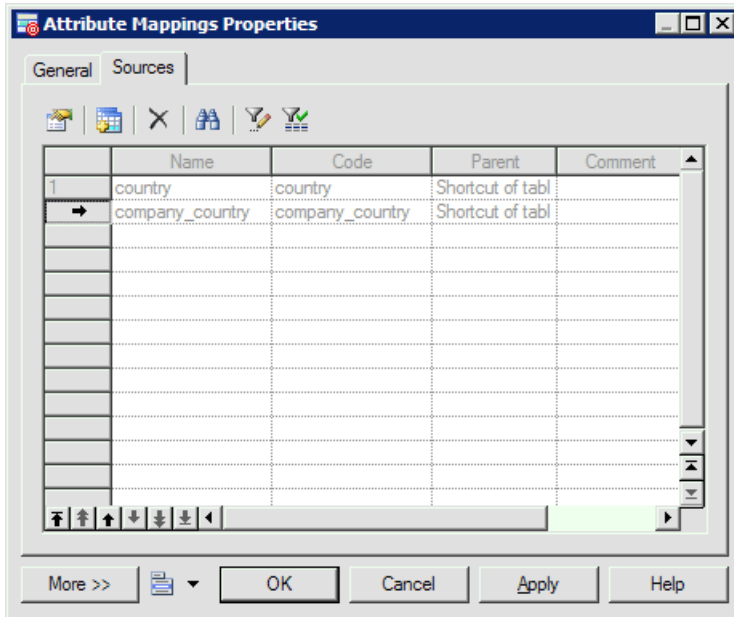

Attribute Mapping

After you have defined class mapping, you can define attribute mappings for the class in the Attributes Mapping sub-tab of the Mapping tab. PowerDesigner will generate some attribute mappings by matching their names with the column names. Click the Add Mappings tool and select the attributes you want to be mapped from the list.

For each attribute, you can select the column to which it is mapped from the list in the Mapped to column. Usually you just have to map each attribute to one column. However, you may need to map the attribute to multiple columns when you define attribute mappings for Value type class for example. In this case, you can open the attribute mappings property sheet and select the Sources tab to add multiple columns.

You can also map the attribute to a formula expression by defining it in the Mapped to box in the General tab. You can construct the formula using the SQL editor.

When an attribute has a Value type class as type, you do not need to define attribute mappings for it. You should instead define mapping for the Value type class.

Primary Identifier Mapping

Columns of primary keys should be mapped to persistent attributes. Like primary keys for tables, you need to set these persistent attributes as primary identifiers of entity classes. The mapped primary keys should be primary keys of primary tables.

There are three types of primary identifier mapping:

- *Simple primary identifier mapping* - the primary key is associated with only one column and the mapped primary identifier has one persistent attribute mapped to the column.
- *Composite primary identifier mapping* - the primary key is associated with more than one column and the mapped primary identifier has the same number of persistent attributes mapped to the columns.

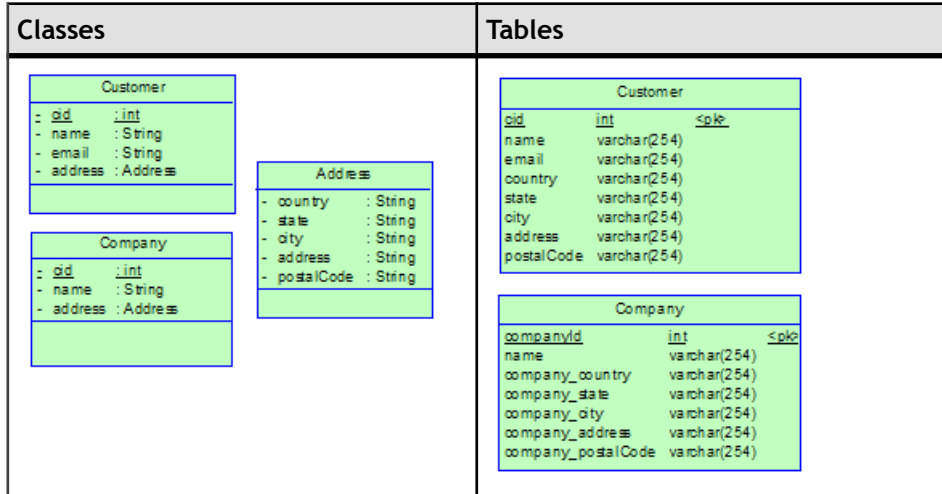

Column(s) of primary keys can be mapped to associations (see *Association Transformation* on page 578). They are migrated from primary keys of other tables.

- *Component primary identifier mapping* - multiple persistent attributes are encapsulated into a value type class, and the mapped primary identifier contains one attribute whose type is the Value type class.

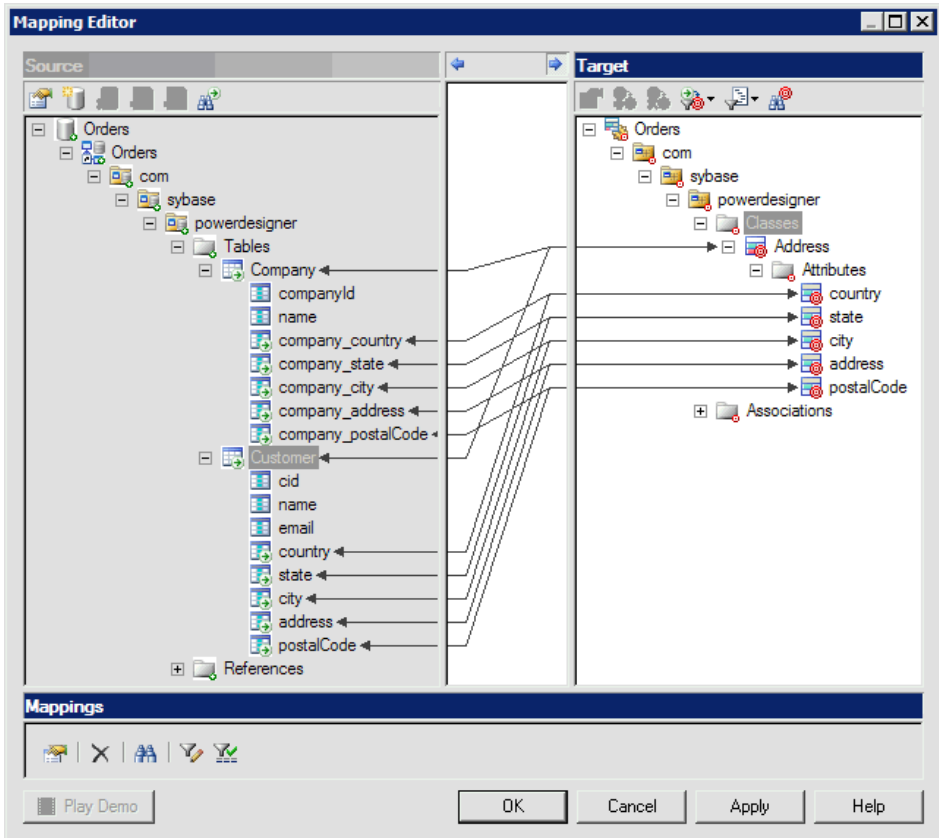

Attributes of value type classes are mapped to columns, which are embedded in primary tables mapped by other entity classes. So you have to add primary tables of the containing classes as value type classes' mapping sources. If the value type class is used in more than

one entity class, you should map each of its persistent attributes to multiple columns of tables of these classes.

For example, Value type class *Address* is used as attribute type for two classes, *Product* and *Customer*. The attributes of the Value type class *Address* can be mapped to columns of two tables, *Company* table and *Customer* table:

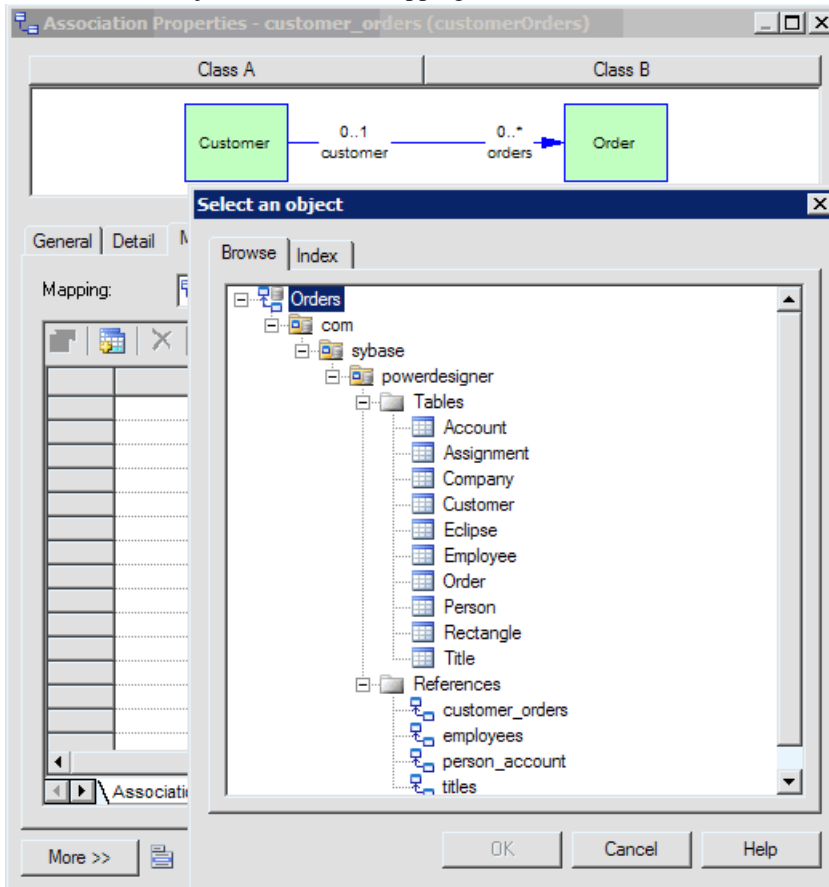

The mapping is easier to visualize in the Mapping Editor.

Primary identifier mapping is mandatory for entity classes.

Association Mapping

You can define association mapping in the Mapping tab of the association property sheet and select the Add Objects tool to add mapping sources.

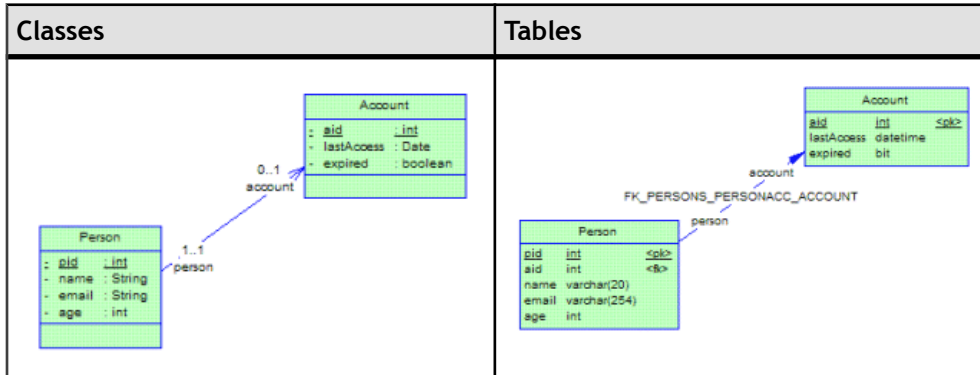

Associations defined between entity classes can be mapped to reference keys or tables. In order to define association mapping, you have to add the references keys or tables as mapping sources. When you add reference keys, the tables on their ends will also be added.

Associations can be classified as one-to-one, one-to-many and many-to-many according to multiplicities of ends. And associations can be classified as unidirectional and bi-directional according to navigability of both ends. Associations of different types should be mapped in different ways. We will introduce them in detail in the following sections.

One-to-One Association Mapping Strategy

You can map each unidirectional one-to-one association to a reference key. The foreign key should have the same direction as the association.

In the following example, there are two entity classes, *Person* and *Account*, and a one-to-one association between them. The association is unidirectional and navigates from the entity class *Person* to the entity class *Account*.

The association and the reference key are linked in the Mapping Editor.

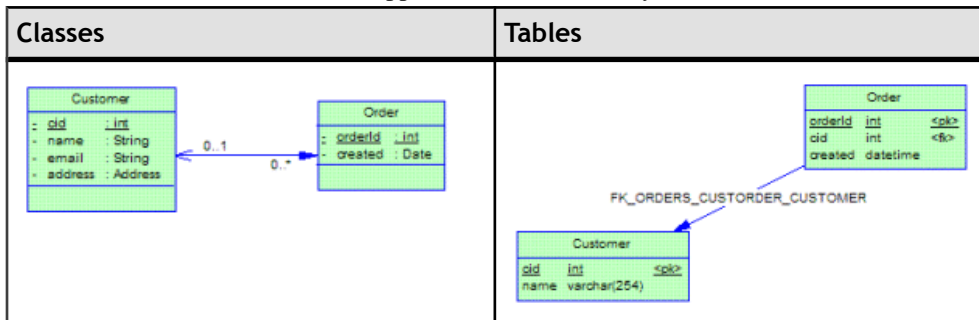

For a bi-directional one-to-one association, you also just can map it to one reference key. But the reference can navigate in either direction.

One-to-Many Association Mapping Strategy

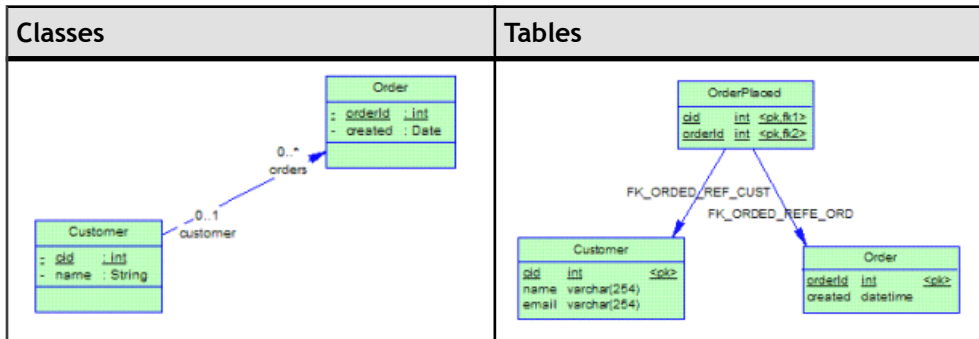

Each unidirectional many-to-one association is mapped to a reference that has the same direction as the association.

In the following example, a unidirectional many-to-one association defined between the class *Customer* and the class *Order* is mapped to the reference key:

Each unidirectional one-to-many association should be mapped to a middle table and two references that refer to tables mapped by the entity classes on both ends.

In the following example, the association defined between *Customer* and *Order* is a unidirectional one-to-many association mapped to a middle table and reference keys:

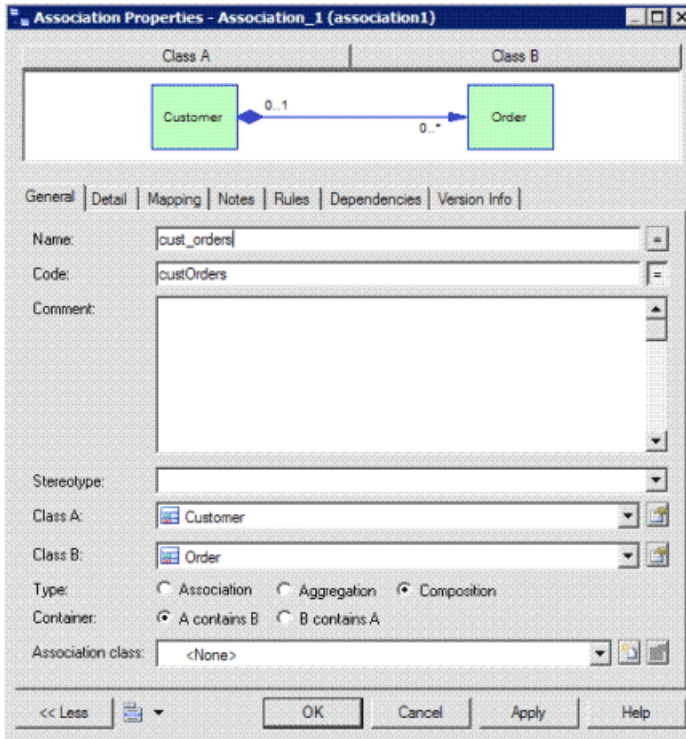

You can map a bi-directional one-to-many association as unidirectional many-to-one association. The reference just can navigate from primary table of class on multiple-valued side to primary table of class on single-valued side.

Sometimes we want to make the primary key of parent table be part of primary key of the child table and reference key join on the migrated column(s). For example we can map *Customer*, *Order* and bi-directional one-to-many association to tables and reference key as follows:

In order to define such type of association mapping, you have to define the association as composition with the class on single-valued side containing the class on multiple-valued side first.

The association is the following:

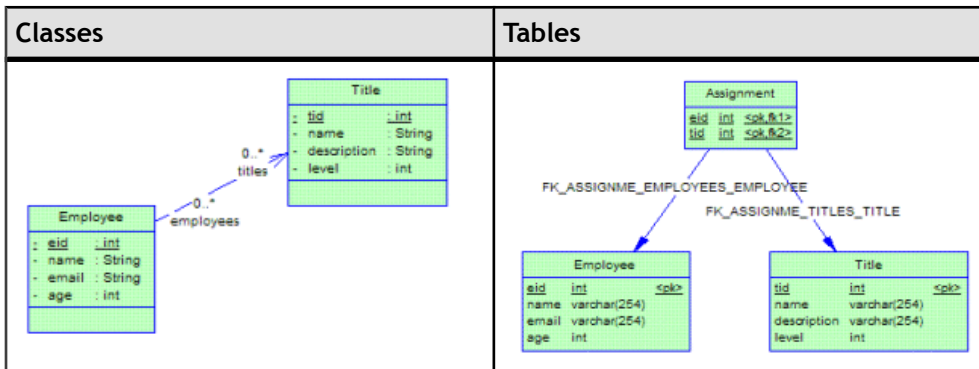

Then add the reference as mapping sources. You just can define the same way association mapping for bi-directional one-to-many association.

Many-to-Many Association Mapping Strategy

Each many-to-many association is mapped to a middle table and two reference keys that refer to tables mapped by entity classes on the two ends.

In the following example a many-to-many association defined between the class *Employee* and the class *Title* is mapped to a middle table and references:

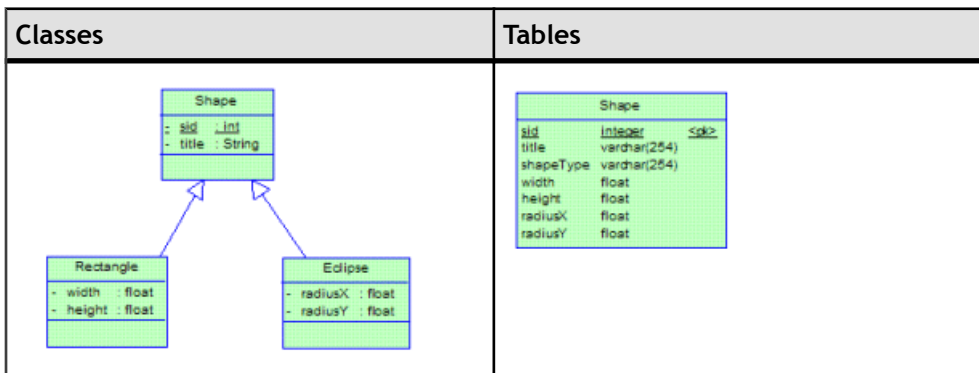

Defining Inheritance Mapping

Inheritance can be mapped using a table per class, joined subclass, or table per class hierarchy inheritance mapping strategy. You can apply any of these inheritance mapping strategies or mix them. You should define primary identifier on the entity class that is the root of the entity hierarchy.

Table Per Class Hierarchy Inheritance Mapping Strategy

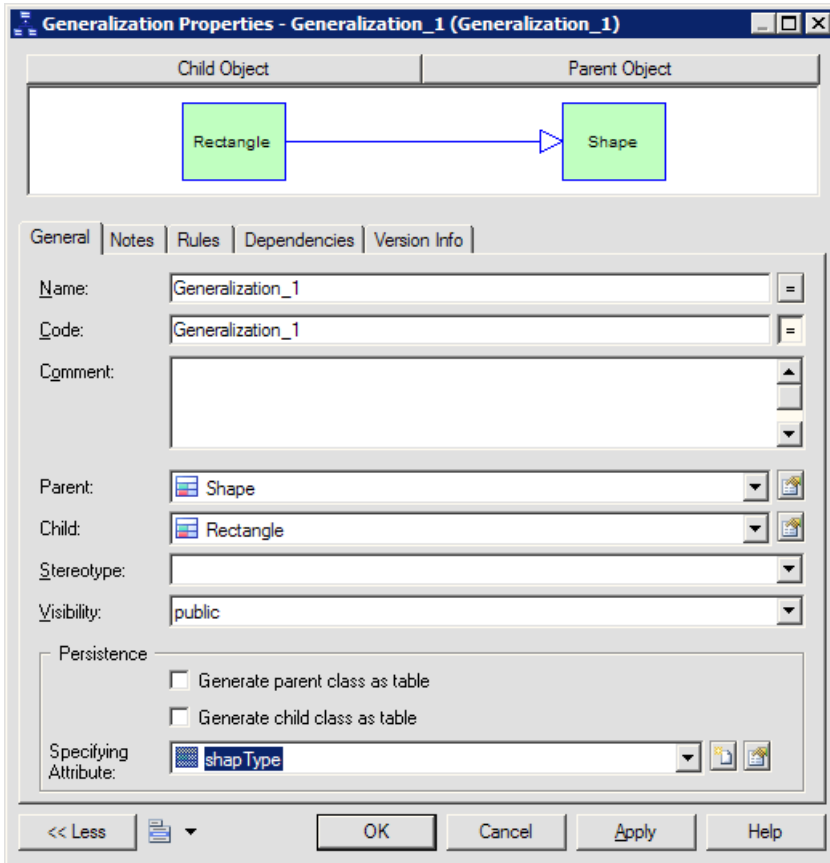

The whole class hierarchy is mapped to one table. One character based type or integer type discriminator column is defined to distinguish instances of difference classes in the hierarchy.

1. Define class mappings for each class in the hierarchy so that all the classes have the same primary table. They can also be mapped to other secondary tables:

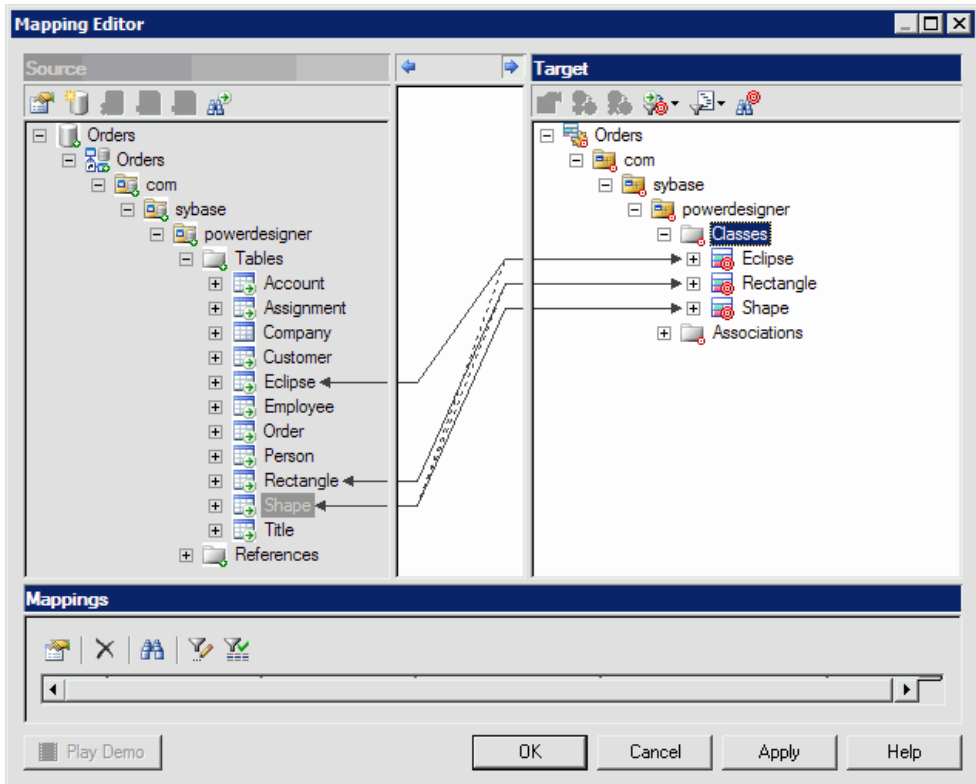

2. Define identifier mapping in the root class.
3. Define attribute mappings or association mappings for each class.
4. Select one of the attributes in the root class, as the Specifying Attribute in the property sheet of one of the children inheritance links of the root class to specify it as a discriminator column, which is used to distinguish between different class instances. In the following example, we define one extra attribute *shapeType* in *Shape* and select it as discriminator attribute:

5. Define persistence generation type for each class. Define the persistence generation type of the root class as *Generate table* and all the other classes as *Migrate columns*.

Joined Subclass Inheritance Mapping Strategy

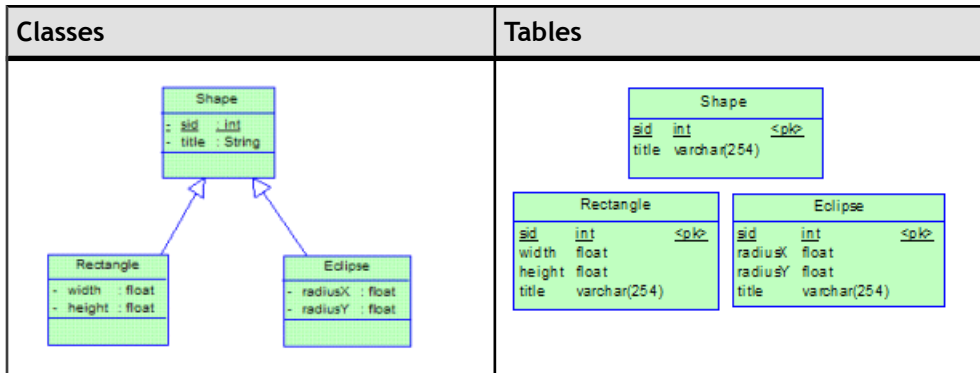

Each entity class is mapped to its own primary table. Each primary table has a reference key referring to a primary table of its parent class except for the primary table of the root class. The reference key should join on the primary key of the primary table.

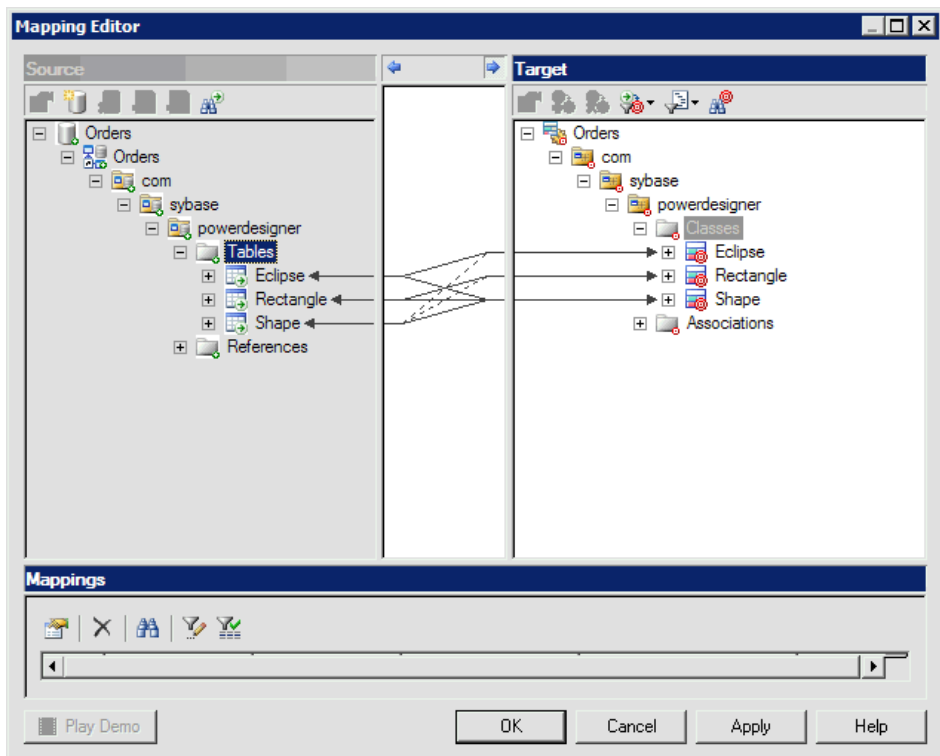

1. Define class mappings for each class in the hierarchy. Each class is mapped to its own primary table.
2. Define identifier mapping in the root class.
3. Define attribute mappings or association mappings for each class.
4. Define persistence generation type for each class.
5. Define persistence generation type of all the classes as *Generate table*.

Table Per Class Inheritance Mapping Strategy

Each class is mapped to its own primary table. All persistent attributes of the class, including inherited persistent attributes, are mapped to columns of the table.

1. Define entity class mappings for each class in the hierarchy, mapping each class to its own primary table:

2. Define attribute mappings and association mappings for each class.

3. Define identifier mapping in the root class.
4. Define persistence generation type for each class.
5. Define persistence generation type of leaf classes as *Generate table* and all the other classes as *Migrate columns*.

Note: Super classes can be also mapped to primary tables of subclasses if inherited persistent attributes are mapped in different ways for subclasses, for example to different columns. The other primary table can just be secondary tables. PowerDesigner will generate these secondary tables for super classes.

For this kind of strategy, some super classes can have no table mapped. These classes are used to define state and mapping information that can be inherited by their subclasses.

CHAPTER 24 Generating Persistent Objects for Java and JSF Pages

PowerDesigner supports the generation of persistent objects for Hibernate and EJB3, as well as JavaServer Faces for Hibernate.

Generating Hibernate Persistent Objects

Hibernate is an open source project developed by JBoss, which provides a powerful, high performance and transparent object/relational persistence and query solution for Java.

Hibernate lets you develop persistent objects using POJO (Plain Old Java Object). All the common Java idioms, including association, inheritance, polymorphism, composition, and the Java collections framework are supported. Hibernate allows you to express queries in its own portable SQL extension (HQL), as well as in native SQL, or with Java-based Criteria and Example objects.

PowerDesigner supports the design of Java classes, database schema and Object/Relational mapping (O/R mapping). Using these metadata, PowerDesigner can generate Hibernate persistent objects including:

- Persistent Java classes (domain specific objects)
- Configuration file
- O/R mapping files
- DAO factory
- Data Access Objects (DAO)
- Unit test classes for automated test

Adding Hibernate Support

To generate Hibernate O/R mapping files that fit in your needs, you need to define Hibernate specific options. PowerDesigner provides support for Hibernate through an extended model definition.

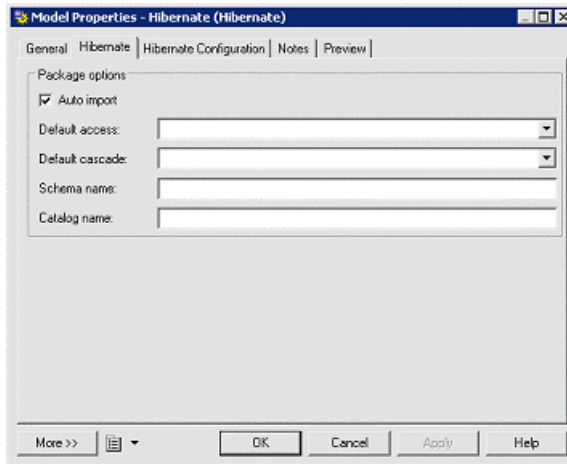

1. Verify that the current model has the target language Java or Java 5.0
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **O/R Mapping** sub-tab, select the **hibernate** item, and click **OK** to attach it to your model.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

Defining the Hibernate Default Options

You can define these options in the model or a package property sheet.

1. Open the model or a package property sheet, and click the Hibernate tab:

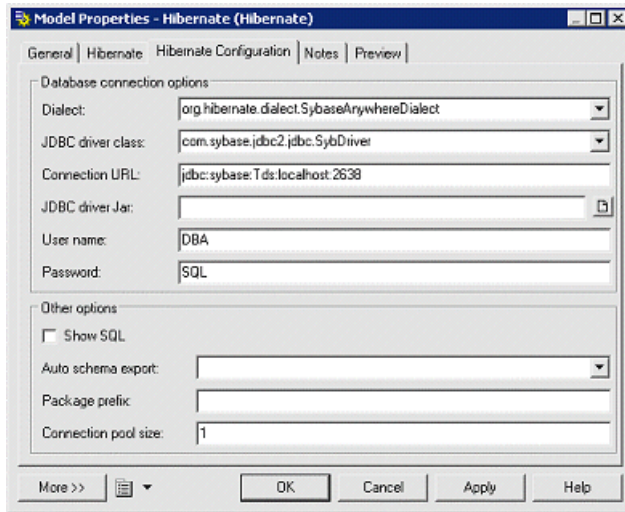

2. Define the model or package level default options.

Option	Description
Auto import	Specifies that users may use an unqualified class name in queries.
Default access	Specifies the default class attribute access type.
Specifies the default cascade	Specifies the default cascade type.
Schema name	Specifies the default database schema name.
Catalog name	Specifies the default database catalog name.

Defining the Hibernate Database Configuration Parameters

Hibernate can support multiple databases. You need to define database configuration parameters. The database configuration parameters are stored in the configuration file, `hibernate.cfg.xml`.

1. Open the model property sheet and click the Hibernate Configuration tab:

2. Define the type of database, JDBC driver, connection URL, JDBC driver jar file path, user name, password, etc.

Option	Description
Dialect	Specifies the dialect, and hence the type of database. Hibert Tag: dialect
JDBC driver class	Specifies the JDBC driver class. Hibert Tag: connection.driver_class
Connection URL	Specifies the JDBC connection URL string. Hibert Tag: connection.url
JDBC driver jar	Specifies the JDBC driver jar file path. Hibert Tag: N/A
User name	Specifies the database user name. Hibert Tag: connection.username
Password	Specifies the database user password. Hibert Tag: connection.password
Show SQL	Specifies that SQL statements should be shown in the log. Hibert Tag: show_sql

Option	Description
Auto schema export	Specifies the mode of creation from tables. Hibert Tag: hbm2ddl.auto
Package prefix	Specifies a namespace prefix for all the packages in the model. Hibert Tag: N/A
Connection pool size	Specifies the maximum number of pooled connections. Hibert Tag: connection.pool_size

You can verify the configuration parameters in the Preview tab.

Defining Hibernate Basic O/R Mappings

There are two kinds of classes in Hibernate, entity classes and value type classes. Entity classes have their own database identities, mapping files and life cycles, while value type classes don't have. Value type classes depend on entity classes. Value type classes are also called component classes.

Hibernate uses mapping files to define the mapping metadata. Each mapping file <Class>.hbm.xml can contain metadata for one or many classes. PowerDesigner uses the following grouping strategy:

- A separate mapping file is generated for each single entity class that is not in an inheritance hierarchy.
- A separate mapping file is generated for each inheritance hierarchy that has a unique mapping strategy. All mappings of subclasses are defined in the mapping file. The mapping file is generated for the root class of the hierarchy. See *Defining Hibernate Inheritance Mappings* on page 621 for details about how the mapping strategy is determined.
- No mapping file is generated for a single value type class that is not in an inheritance hierarchy. Its mapping is defined in its owner's mapping file.

Defining Hibernate Class Mapping Options

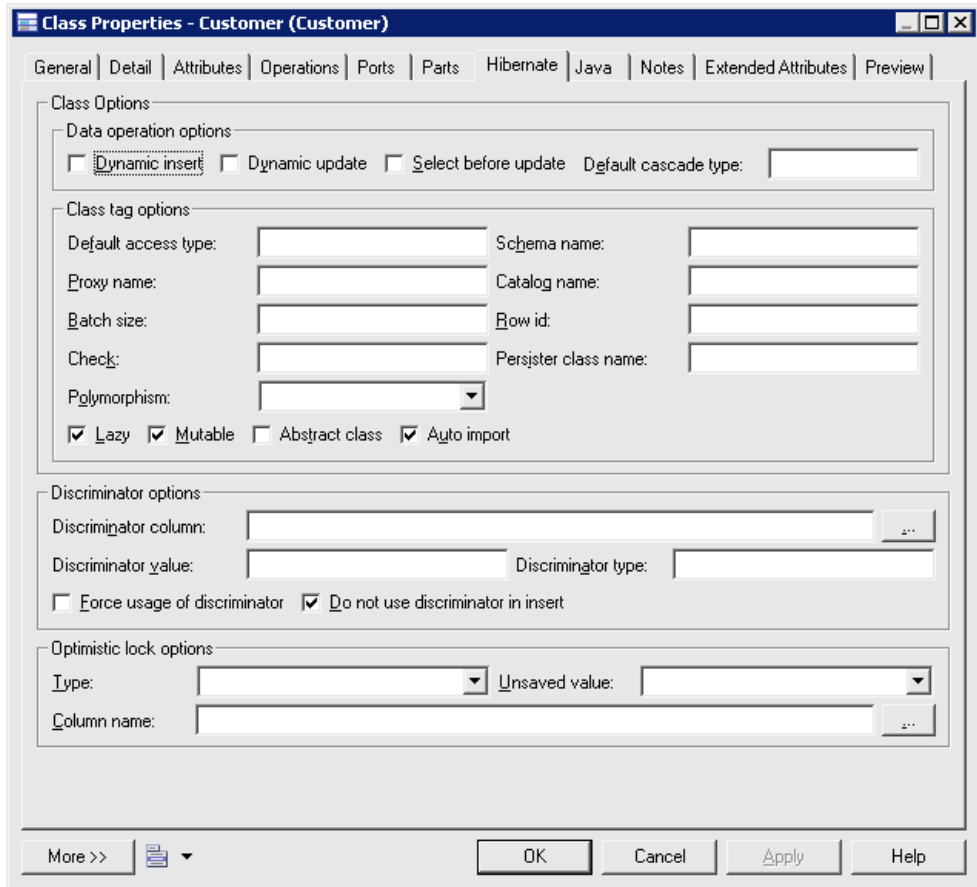

Classes can be mapped to tables or views. Since views have many constraints and limited functionality (for example they do not have primary keys and reference keys), some views cannot be updated, and the mappings may not work properly in some cases.

There are some conditions that need to be met in order to generate mapping for a specific class:

- The Java source can be generated. This may not be possible if, for example, the visibility of the class is private.
- The class is persistent.

- The generation mode is not set to Generate ADT (abstract data type).
- If the class is an inner class, it must be static, and have public visibility. Hibernate should then be able to create instances of the class.

Hibernate-specific class mapping options can be defined in the Hibernate tab of the class property sheet:

Option	Description
Dynamic insert	Specifies that INSERT SQL should be generated at runtime and will contain only the columns whose values are not null. Hibernate Tag: dynamic-insert
Dynamic update	Specifies that UPDATE SQL should be generated at runtime and will contain only the columns whose values have changed. Hibernate Tag: dynamic-update

Option	Description
Select before update	Specifies that Hibernate should never perform a SQL UPDATE unless it is certain that an object is actually modified. Hibernate Tag: select-before-update
Default cascade type	Specifies the default cascade style. Hibernate Tag: default-cascade
Default access type	Specifies the default access type (field or property) Hibernate Tag: default-access
Proxy name	Specifies an interface to use for lazy initializing proxies. Hibernate Tag: proxy
Batch size	Specifies a "batch size" for fetching instances of this class by identifier. Hibernate Tag: batch-size
Check	Specifies a SQL expression used to generate a multi-row check constraint for automatic schema generation. Hibernate Tag: check
Polymorphism	Specifies whether implicit or explicit query polymorphism is used. Hibernate Tag: polymorphism
Schema name	Specifies the name of the database schema. Hibernate Tag: schema
Catalog name	Specifies the name of the database catalog. Hibernate Tag: catalog
Row id	Specifies that Hibernate can use the ROWID column on databases which support it (for example, Oracle). Hibernate Tag: rowed
Persister class name	Specifies a custom persistence class. Hibernate Tag: persister
Lazy	Specifies that the class should be lazy fetching. Hibernate Tag: lazy
Mutable	Specifies that instances of the class are mutable. Hibernate Tag: mutable
Abstract class	Specifies that the class is abstract. Hibernate Tag: abstract

Option	Description
Auto import	Specifies that an unqualified class name can be used in a query Hibernate Tag: Auto-import
Discriminator column	Specifies the discriminator column or formula for polymorphic behavior in a one table per hierarchy mapping strategy. Hibernate Tag: discriminator
Discriminator value	Specifies a value that distinguishes individual subclasses, which are used for polymorphic behavior. Hibernate Tag: discriminator-value
Discriminator type	Specifies the discriminator type. Hibernate Tag: type
Force usage of discriminator	Forces Hibernate to specify allowed discriminator values even when retrieving all instances of the root class. Hibernate Tag: force
Do not use discriminator in insert	Forces Hibernate to not include the column in SQL INSERTs Hibernate Tag: insert
Optimistic lock type	Specifies an optimistic locking strategy. Hibernate Tag: optimistic-lock
Optimistic lock column name	Specifies the column used for optimistic locking. A field is also generated if this option is set. Hibernate Tag: version/ timestamp
Optimistic lock unsaved value	Specifies whether an unsaved value is null or undefined. Hibernate Tag: unsaved-value

Defining Primary Identifier Mappings

Primary identifier mapping is mandatory in Hibernate. Primary identifiers of classes are mapped to primary keys of master tables in data sources. If not defined, a default primary identifier mapping will be generated, but this may not work properly.

There are three kinds of primary identifier mapping in Hibernate:

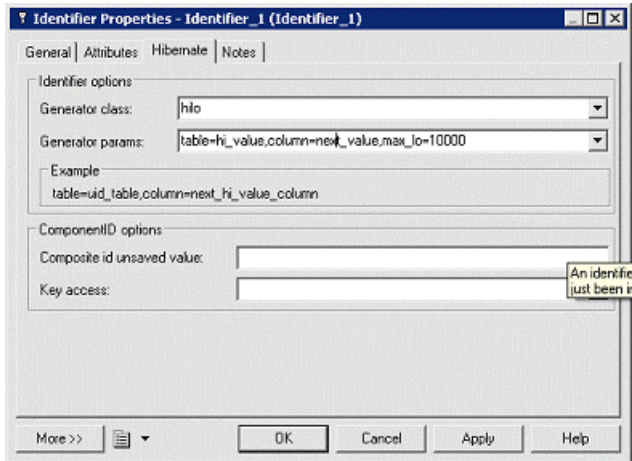

- Simple identifier mapping
- Composite identifier mapping
- Component identifier mapping

Mapped classes must declare the primary key column of the database table. Most classes will also have a Java-Beans-style property holding the unique identifier of an instance.

Simple Identifier Mapping

When a primary key is attached to a single column, only one attribute in the primary identifier can be mapped. This kind of primary key can be generated automatically. You can define the generator class and parameters. There are many generator class types, such as increment, identity, sequence, etc. Each type of generator class may have parameters that are meaningful to it. See your Hibernate documentation for detailed information.

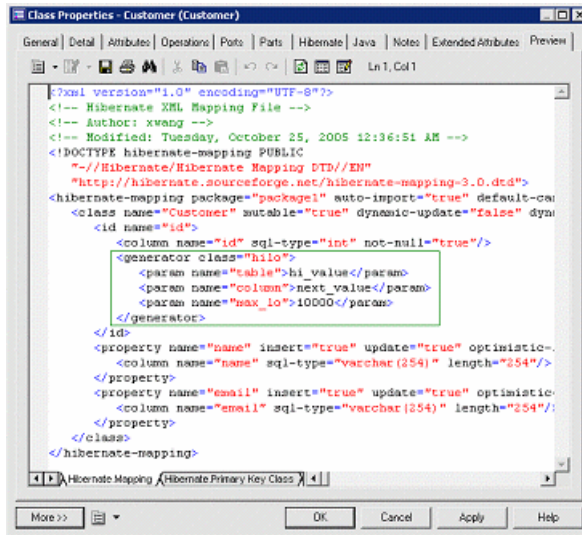

You can define the generator class and parameters in the Hibernate tab of the primary identifier property sheet. The parameters take the form of param1=value1; param2=value2.

1. Open the class property sheet and click the Attributes tab.
2. Create an attribute and set it as the Primary identifier.
3. Click the Identifiers tab and double-click the entry to open its property sheet.
4. Click the Hibernate tab, select a generator class and define its parameters.

Example parameters:

- Select hilo in the Generator class list
 - Enter "table=hi_value,column=next_value,max_lo=10000" in the Generator params box. You should use commas to separate the parameters.
5. You can check the code in the Preview tab:

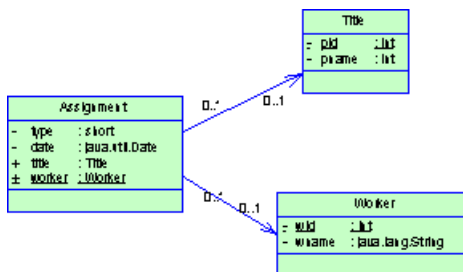

Note that, if there are several Primary identifier attributes, the generator is not used.

Composite Identifier Mapping

If a primary key comprises more than one column, the primary identifier can have multiple attributes mapped to these columns. In some cases, the primary key column could also be the foreign key column.

1. Define association mappings.
2. Migrate navigable roles of associations.
3. Add these migrated attributes in primary identifier. The migrated attributes need not to be mapped.

In the above example, the Assignment class has a primary identifier with three attributes: one basic type attribute and two migrated attributes. The primary identifier mapping is as follows:

```

<composite-id>
  <key-property name="type">
    <column name="type" sql-type="smallint"
      not-null="true"/>
  </key-property>

```

```

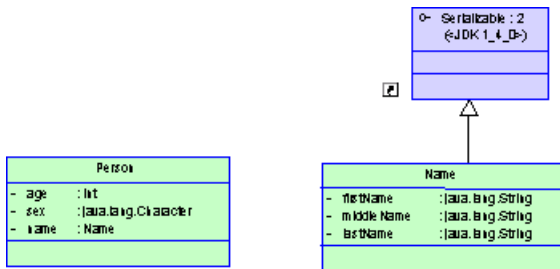

<key-many-to-one name="title">
</key-many-to-one>
<key-many-to-one name="worker">
</key-many-to-one>
</composite-id>

```

Component Primary Identifier Mapping

For more convenience, a composite identifier can be implemented as a separate value type class. The primary identifier has just one attribute with the class type. The separate class should be defined as a value type class. Component class mapping will be generated then.

1. Define a primary identifier attribute.
2. Define the type of the attribute as a value type class.
3. Set the Class generation property of the primary identifier attribute to Embedded.
4. Set the ValueType of the primary identifier class to true.
5. Define a mapping for the primary identifier class.

In the example above, three name attributes are grouped into one separate class Name. It is mapped to the same table as Person class. The generated primary identifier is as follows:

```

<composite-id name="name" class="identifier.Name">
<key-property name="firstName">
<column name="name_firstName"
sql-type="text" />
</key-property>
<key-property name="middleName">
<column name="name_middleName"
sql-type="text" />
</key-property>
<key-property name="lastName">
<column name="name_lastName"
sql-type="text" />
</key-property>
</composite-id>

```

Note: The value type class must implement the java.io.Serializable interface, which implements the equals() and hashCode() methods.

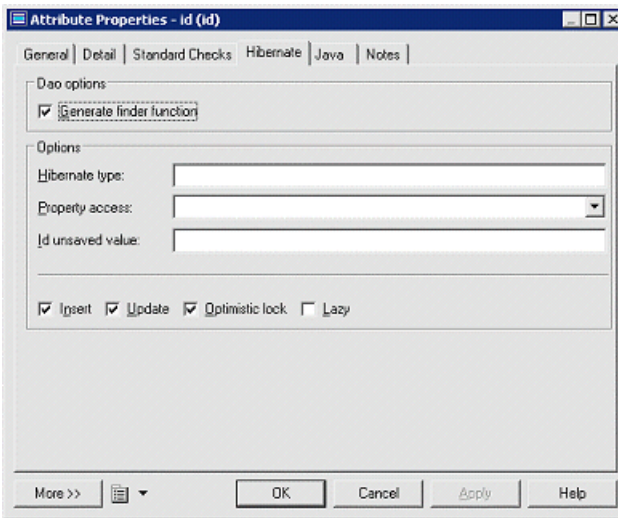

Defining Attribute Mappings

Attributes can be migrated attributes or ordinary attributes. Ordinary attributes can be mapped to columns or formulas. Migrated attributes do not require attribute mapping.

The following types of mapping are possible:

- Map attribute to formula - When mapping an attribute to a formula, you should ensure that the syntax is correct. There is no column in the source table of the attribute mapping.
- Component attribute mapping - A component class can define the attribute mapping as for other classes, except that there is no primary identifier.
- Discriminator mapping - In inheritance mapping with a one-table-per-hierarchy strategy, the discriminator needs to be specified in the root class. You can define the discriminator in the Hibernate tab of the class property sheet.

Hibernate-specific attribute mapping options are defined in the Hibernate tab of the Attribute property sheet.

Option	Description
Generate finder function	Generates a finder function for the attribute.
Hibernate type	Specifies a name that indicates the Hibernate type.
Property access	Specifies the strategy that Hibernate should use for accessing the property value.
Id unsaved value	Specifies the value of an unsaved id.
Insert	Specifies that the mapped columns should be included in any SQL INSERT statements.

Option	Description
Update	Specifies that the mapped columns should be included in any SQL UPDATE statements.
Optimistic lock	Specifies that updates to this property require acquisition of the optimistic lock.
Lazy	Specifies that this property should be fetched lazily when the instance variable is first accessed (requires build-time byte code instrumentation).

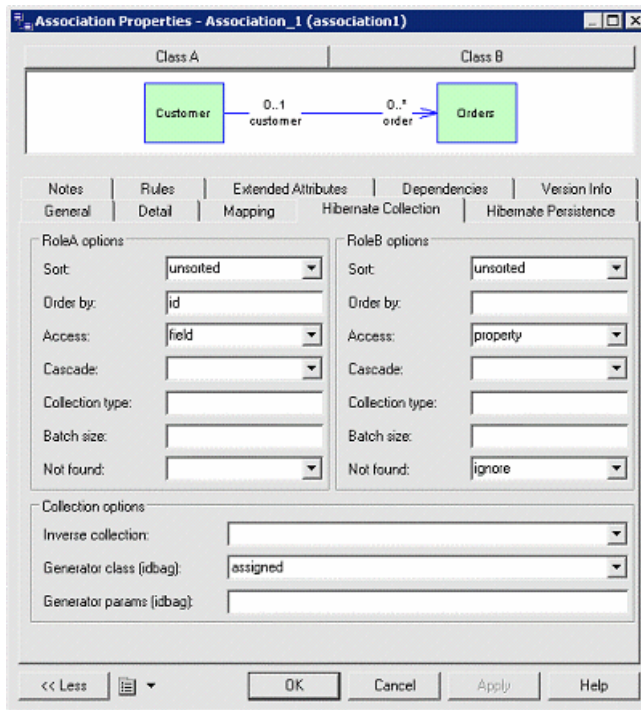

Hibernate Association Mappings

Hibernate supports one-one, one-to-many/many-to-one, and many-to-many association mappings. The mapping modeling is same with standard O/R Mapping Modeling. However, Hibernate provides special options to define its association mappings, which will be saved into <Class>.hbm.xml mapping file. PowerDesigner allows you to define standard association attributes like Container Type implementation class, role navigability, array size and specific extended attributes for Hibernate association mappings.

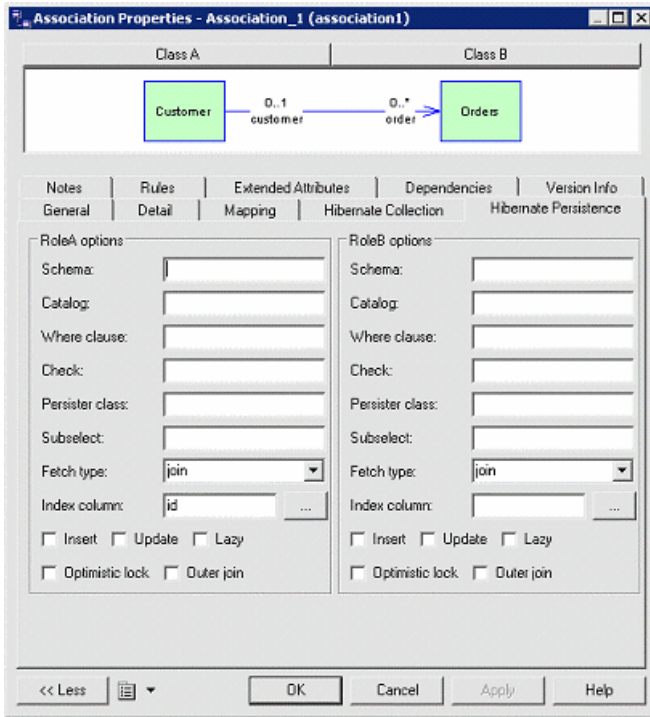

Defining Hibernate Association Mapping Options

You define Hibernate association mapping options as follows:

1. Open the Association property sheet and click the Hibernate Collection tab.
2. Define the collection management options (see *Collection management options* on page 618).

3. Select the Hibernate Persistence tab. Define persistence options (see *Persistence options* on page 619).

Collection Management Options

The following options are available:

Field	Description
Sort	Specifies a sorted collection with natural sort order, or a given comparator class. Hibernate Tag: sort
Order by	Specifies a table column (or columns) that define the iteration order of the Set or bag, together with an optional asc or desc. Hibernate Tag: order-by
Access	Specifies the strategy Hibernate should use for accessing the property value. Hibernate Tag: access
Cascade	Specifies which operations should be cascaded from the parent object to the associated object. Hibernate Tag: cascade
Collection type	Specifies a name that indicates the Hibernate type. Hibernate Tag: type

Field	Description
Batch size	Specifies the batch load size. Hibernate Tag: batch-size
Not found	Specifies how foreign keys that reference missing rows will be handled: ignore will treat a missing row as a null association. Hibernate Tag: not-found
Inverse collection	Specifies that the role is the inverse relation of the opposite role. Hibernate Tag: inverse

Persistence Options

The following options are available:

Field	Description
Schema	Specifies the name of the schema. Hibernate Tag: schema
Catalog	Specifies the name of the catalog. Hibernate Tag: catalog
Where clause	Specifies an arbitrary SQL WHERE condition to be used when retrieving objects of this class. Hibernate Tag: where
Check	Specifies a SQL expression used to generate a multi-row check constraint for automatic schema generation. Hibernate Tag: check
Fetch type	Specifies outer-join or sequential select fetching. Hibernate Tag: fetch
Persister class	Specifies a custom persistence class. Hibernate Tag: persister
Subselect	Specifies an immutable and read-only entity to a database subselect. Hibernate Tag: subselect
Index column	Specifies the column name if users use list or array collection type. Hibernate Tag: index
Insert	Specifies that the mapped columns should be included in any SQL INSERT statements. Hibernate Tag: insert

Field	Description
Update	Specifies that the mapped columns should be included in any SQL UPDATE statements. Hibernate Tag: update
Lazy	Specifies that this property should be fetched lazily when the instance variable is first accessed. Hibernate Tag: lazy
Optimistic lock	Specifies that a version increment should occur when this property is dirty. Hibernate Tag: optimistic-lock
Outer join	Specifies to use an outer-join. Hibernate Tag: outer-join

Mapping Collections of Value Types

If there is a value type class on the navigable role side of an association with a multiplicity of one, PowerDesigner will embed the value type in the entity type as a composite attribute.

Mapping Collections of Value Type

You define mapping collections of value type as follows:

1. Create an entity type class.
2. Create another class for value type.
3. Open the property sheet of the class, click the Detail tab, and select the Value type radio button.
4. Create an association between the value type class and an entity type class. On the value type side, set the multiplicity to one and the navigability to true.

5. Generate the PDM with O/R mapping.
6. Open the property sheet of the entity class and click the Preview tab.
7. Verify the mapping file.

A composite entity class may contain components, using the <nested-composite-element> declaration.

Defining Association Collection Type for One-to-many or Many-to-many Associations

You define association collection type for one-to-many or many-to-many associations as follows:

1. Open the association property sheet and click the Detail tab.
2. Specify a Multiplicity on both sides.
3. Specify either unidirectional or bi-directional navigability.
4. Specify role names if necessary.
5. If one role of the association is navigable and the multiplicity is many, you can set the collection container type and batch loading size.
6. If you select `java.util.List` or `<none>`, it implies that you want to use an array or list-indexed collection type. Then you should define an index column to preserve the objects collection order in the database.

Note: The Java collection container type conditions the Hibernate collection type.

Collection Container Type	Hibernate Collection Type
<None>	array
<code>java.util.Collection</code>	bag or idbag (many-to-many)
<code>java.util.List</code>	list
<code>java.util.Set</code>	set

Defining Hibernate Inheritance Mappings

Hibernate supports the three basic inheritance mapping strategies:

- Table per class hierarchy
- Table per subclass
- Table per concrete class
- There are not any special different from standard inheritance mapping definition in O/R Mapping Modeling. However, a separate mapping file is generated for each inheritance hierarchy that has a unique mapping strategy. All mappings of subclasses are defined in the mapping file. The mapping file is generated for the root class of the hierarchy.

Generating Code for Hibernate

Before generating code for Hibernate, you need to:

- Install Hibernate 3.0 or higher.
- Check the model.

- Define generation options.

Checking the Model

When you complete the definition of the model, you need to run the Check Model function to verify if there are errors or warnings in the model. If there are errors, you need to fix them before generating code.

Defining Generation Options

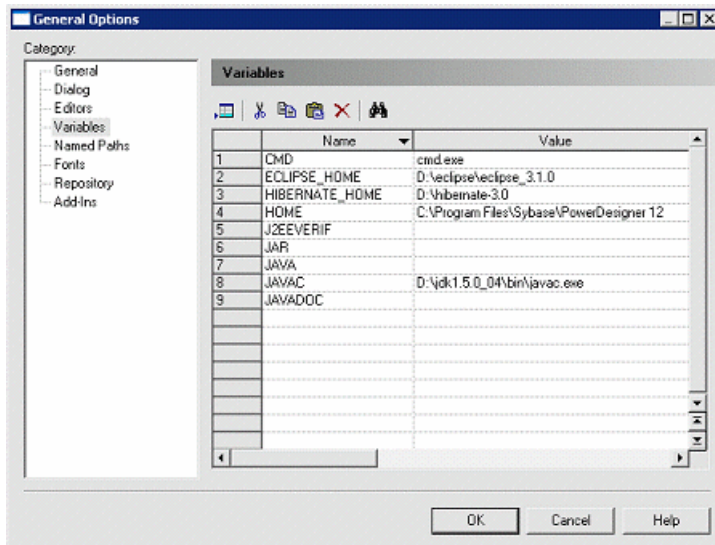

There are two types of generation options:

- Environment variables - to allow your Eclipse or Ant build script to find the Hibernate library Jar files
- Generation options

Defining Environment Variables

You define environment variables as follows:

1. Select **Tools > General Options**.

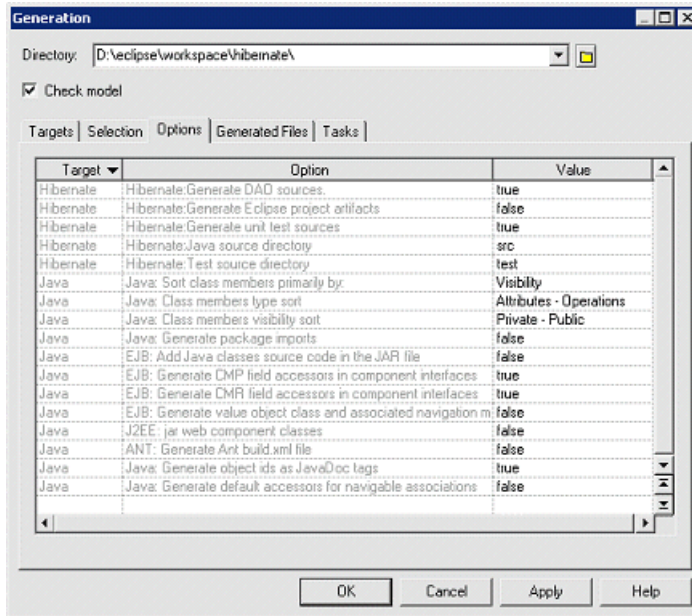

2. Select the Variables node.
3. Add a variable HIBERNATE_HOME and, in the value field, enter the Hibernate home directory path. For example, D:\Hibernate-3.0.

Defining Generation Options

You define generation options as follows:

1. Select **Language > Generate Java Code**.

- Specify the root directory where you want to generate the code.
- Click the Options tab.

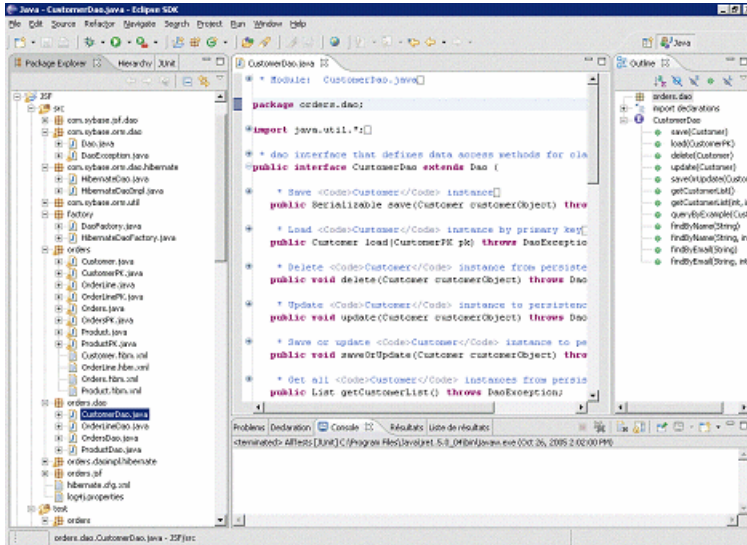

- [optional] To use DAO, set the Generate DAO sources option to true.
- [optional] To use Eclipse to compile and test the Java classes, set the Generate Eclipse project artifacts option to true.
- [optional] To use unit test classes to test the Hibernate persistent objects, set the Generate unit test sources option to true.
- Click on OK to generate code immediately or Apply and then Cancel to save your changes for later.

Generating Code for Hibernate

Once you have completed your model, checked it, and defined your generation options, you can generate the code for Hibernate.

- Select **Language > Generate Java Code**.
- [optional] Click the Select tab to change the object selection.
- [optional] Click the Options tab to change the Hibernate and Java generation options.
- [optional] Click the Generated Files tab to review all the files that will be generated.
- Click OK.

You can use an IDE like Eclipse to modify the generated code, compile, run the unit test and develop your application.

Using the Generated Hibernate Code

To use Eclipse, you need to download and install the Eclipse SDK.

Importing the Generated Project into Eclipse

If you have selected the Generate Eclipse project artifacts generation option, you can import the generated project into Eclipse and use Eclipse to modify, compile and run the tests.

If you use the PowerDesigner Eclipse plugin then, after the code generation, the project is automatically imported or refreshed in Eclipse.

If you use the standalone version of PowerDesigner, you need to import the generated project as follows:

1. In Eclipse, select **File > Import**
2. In the import list, select Existing Projects into Workspace. Eclipse will automatically compile all the Java classes. If there are errors, you should check:
 - That all the required Jar files are included in the .classpath file.
 - That the JDK version is the right one. If you use Java 5.0 as the language in OOM, you need to use the JDK 5.0 to compile the code.

Performing the Unit Tests

If the generated Java classes are compiled without error, you can run the unit tests within Eclipse or using Ant.

The unit tests generate random data to create and update objects.

After creating, updating, deleting or finding objects, a test asserts that the result is as expected.

If the result is as expected, the test succeeds; otherwise it fails.

Before running the unit tests, you need to:

1. Create the database file.
2. Define an ODBC connection.
3. Generate the database from the PDM using the ODBC connection.
4. Give the test user the permission to connect to the database.
5. Start the database.

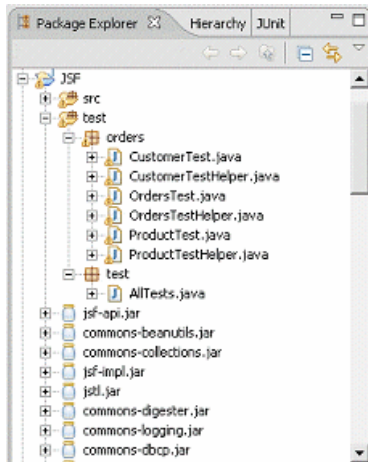

Running Unit Tests in Eclipse

Eclipse integrates JUnit. The JUnit Jar files and JUnit user-interface are provided.

Running a Single Test Case

You run a single test case as follows:

1. Open the Java perspective
2. In the Package Navigator, expand the test package

3. Right-click on a test case (for example, CustomerTest.java) and select **Run As > JUnit Test**.
4. Select the JUnit view to verify the result:

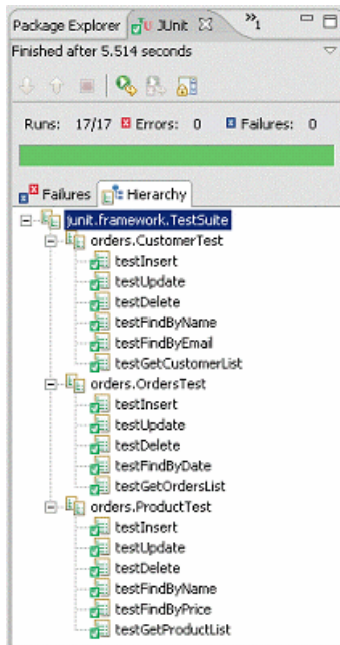

If there are 0 errors, then the test has succeeded. If there are errors, you need to check the Console view to locate the sources of them. The problem could be:

- The database is not started.
- The user name or password is wrong.
- The database is not generated.
- The mapping is wrong.

Running the Test Suite

You run the test suite as follows

1. Open the Java perspective
2. In the Package Navigator, expand the test package
3. Right-click on the AllTests.java test suite and select **Run As > JUnit Test**.
4. Select the JUnit view to verify the result

Running Unit Tests with Ant

To generate the Ant build.xml file, you need to select the Generate Ant build.xml file in the Java code generation window.

To use Ant, you need to:

- Download it from <http://www.apache.org> and install it.
- Define an environment variable ANT_HOME and set it to your Ant installation directory.
- Copy junit-3.8.1.jar from HIBERNATE_HOME/lib directory to ANT_HOME/lib directory.
- Make sure that the Hibernate Jar files are defined in the build.xml file or in the CLASSPATH environment variable.
- Make sure that the JDBC driver Jar file of your database is defined in the build.xml file or in the CLASSPATH environment variable.

Running Unit Tests with Ant from PowerDesigner:

You run unit tests with Ant from PowerDesigner as follows:

1. Select **Language > Generate Java Code**.
2. Select the Options tab.
3. Set the Generate Ant build.xml file option to true.
4. Select the Tasks tab.

5. Check the Hibernate: Run the generated unit tests task.
6. Click OK.
7. After you close the generation files list window, the JUnit task runs. You can see the result in output window.

```

compiletest:
[mkdir] Created dir: C:\Documents and Settings\yayu\My Documents\PD\Code\build\testclasses
[javac] Compiling 8 source files to C:\Documents and Settings\yayu\My Documents\PD\Code\build\testclasses

unit:
[mkdir] Created dir: C:\Documents and Settings\yayu\My Documents\PD\Code\testout
[junit] Running general.SingleClass_InnerClass_InnerInnerClass Test
[junit] Tests run: 4, Failures: 0, Errors: 0, Time elapsed: 4.842 sec
[junit] Tests run: 4, Failures: 0, Errors: 0, Time elapsed: 0.031 sec
[junit] Tests run: 4, Failures: 0, Errors: 0, Time elapsed: 0.061 sec
[junit] Tests run: 4, Failures: 0, Errors: 0, Time elapsed: 0.139 sec

BUILD SUCCESSFUL
Total time: 9 seconds

```

Running Unit Tests with Ant from the Command Line

You run unit tests with Ant from the command line as follows:

1. Open a command line window.
2. Go to the directory where you have generated the code.
3. Run the JUnit test task: Ant junit
4. Check the output result.

Generating EJB 3 Persistent Objects

EJB 3.0 is the latest revision of the Enterprise Java Beans specification. One of the principal goals of EJB 3.0 is: "Simplification of object persistence by the definition of a light-weight object/relational mapping facility based on the direct use of Java classes rather than persistent components."

One of the most significant changes in EJB 3.0 is the introduction of a standard O/R mapping specification and the move to POJO based persistence.

EJB 3.0 persistence provides a lightweight persistence solution for Java applications. It supports powerful, high performance and transparent object/relational persistence, which can be used both in container and out of container.

EJB 3.0 persistence lets you develop persistent objects using POJO (Plain Old Java Object). All the common Java idioms, including association, inheritance, polymorphism, composition, and the Java collections framework are supported. EJB 3.0 persistence allows you to express queries in its own portable SQL extension (EJBQL), as well as in native SQL.

PowerDesigner supports the design of Java classes, database schema and Object/Relational mapping (O/R mapping). Using these metadata, PowerDesigner can generate codes for EJB 3 persistence, including:

- Persistent EJB Entities (domain specific objects)

- Configuration file
- O/R mapping files (Optional)
- DAO factory
- Data Access Objects (DAO)
- Unit test classes for automated test

Generating Entities for EJB 3.0

You generate entities for EJB 3.0 as follows:

1. Create an OOM and a PDM, and then define your O/R mappings. For detailed information, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.
2. Define the EJB 3 persistence settings.
3. Generate Java code.
4. Run unit tests.

Adding EJB 3 Persistence Support

PowerDesigner uses an EJB 3.0 Extended Model Definition to generate EJB 3.0 persistence artifacts.

1. Select **Model > Extended Model Definitions**, and click the **Import** tool.
2. Click the **O/R Mapping** sub-tab, select the EJB 3.0 xem, and click **OK** to attach it to your model.
3. Click **OK** to close the List of Extended Model Definitions and return to your model.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

Defining EJB 3 Basic O/R Mapping

There are three kinds of persistent classes in EJB 3:

- Entity classes
- Embeddable classes
- Mapped superclasses

The following requirements apply to persistent classes:

- They must be defined as persistent classes (see *Entity Class Transformation* on page 575).
- They must be top level classes (and not inner classes).
- Entity classes and Mapped superclasses should carry the EJBEntity stereotype.
- Embeddable classes are Value type classes, i.e. persistent classes with a Value type persistent type.

Classes that do not meet these requirements will be ignored.

Tip: You can set the stereotype and persistence of all the classes in a model or package (and sub-packages) by right-clicking the model or package and selecting Make Persistent from the contextual menu.

Defining Entity Mappings

Set the stereotype of persistent classes to make them EJB 3 Entity classes.

The Entity annotation is generated to specify that the class is an entity.

```
@Entity
@Table(name="EMPLOYEE")
public class Employee { ... }
```

For more informations about defining entity class mappings, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

EJB 3 Entity Mapping Options

The following EJB3-specific mapping options can be set on the EJB 3 Persistence tab of the class property sheet.

Option	Description
Entity Name	Specifies that the class alias that can be used in EJB QL.
Access strategy	Specifies the default access type (FIELD or PROPERTY)
Schema name	Specifies the name of the database schema.
Catalog name	Specifies the name of the database catalog.
Mapping definition type	Specifies what will be generated for mapping meta data, the mapping file, annotations or both.
Discriminator value	Specifies the discriminator value to distinguish instances of the class

Mapping to Multiple Tables

In EJB 3, Entity classes can be mapped to multiple tables. For more for information on how to map one Entity class to multiple tables, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

There is a check to guarantee that secondary tables have reference keys referring to primary tables.

The SecondaryTable annotation is generated to specify a secondary table for the annotated Entity class. The SecondaryTables annotation is used when there are multiple secondary tables for an Entity.

Defining Primary Identifier Mapping

Three kinds of primary identifier mapping are supported in EJB 3.0:

- Simple identifier mapping - This kind of primary key can be generated automatically in EJB 3. You can define the generator class and parameters. There are four generator class types, Identity, Sequence, Table and Auto. Table generator and sequence generators require certain parameters. See the EJB 3.0 persistence specification for details.

You can define the generator class and parameters in the EJB 3 persistence tab of primary identifiers' property sheet. The parameters take the form param1=value1; param2=value2.

The Id annotation generated specifies the primary key property or field of an entity. The GeneratedValue annotation provides for the specification of generation strategies for the values of primary keys:

```
@Id
@GeneratedValue(strategy=GenerationType.TABLE,
generator="customer_generator")
@TableGenerator(
    name=" customer_generator",
    table="Generator_Table",
    pkColumnName="id",
    valueColumnName="curr_value",
    initialValue=4
)
@Column(name="cid", nullable=false)
```

- Composite identifier mapping - The IdClass annotation will be generated for an entity class or a mapped superclass to specify a composite primary key class that is mapped to multiple fields or properties of the entity:

```
@IdClass(com.acme.EmployeePK.class)
@Entity
public class Employee {
    @Id String empName;
    @Id Date birthDay;
    ...
}
```

- Embedded primary identifier mapping - corresponds to component primary identifier mapping. The EmbeddedId annotation is generated for a persistent field or property of an entity class or mapped superclass to denote a composite primary key that is an embeddable class:

```
@EmbeddedId
protected EmployeePK empPK;
```

Defining Attribute Mappings

Each persistent attribute with basic types can be mapped to one column. Follow instructions to define attribute mappings for this kind of persistent attributes.

The following EJB3-specific attribute mapping options are available on the EJB 3 Persistence tab of each attribute's property sheet:

Option	Description
Version attribute	Specifies if attribute is mapped as version attribute
Insertable	Specifies that the mapped columns should be included in any SQL INSERT statements.
Updatable	Specifies that the mapped columns should be included in any SQL UPDATE statements.
Fetch	Specify if attribute should be fetched lazily.
Generate finder	Generates a finder function for the attribute.

The Basic annotation is generated to specify fetch mode for the attribute or property and whether the attribute or property is mandatory. The Column annotation is generated to specify a mapped column for a persistent property or field.

```
@Basic
@Column(name="DESC", nullable=false, length=512)
public String getDescription() { return description; }
```

Other Annotations can also be generated to specify the persistence type of an attribute or property. A Temporal annotation specifies that a persistent property or attribute should be persisted as a temporal type. There is also the enumerated annotation for enumerated types and Lob for large object types.

Defining Versioning Mapping

EJB 3.0 uses managed versioning to perform optimistic locking. If you want to use this kind of feature, you need to set one mapped persistent attribute as the Version attribute, by selecting the Version attribute option on the EJB 3 Persistence tab. The following types are supported for Version attribute: int, Integer, short, Short, long, Long, Timestamp.

The Version attribute should be mapped to the primary table for the entity class. Applications that map the Version property to a table other than the primary table will not be portable. Only one Version attribute should be defined for each Entity class.

The Version annotation is generated to specify the version attribute or property of an entity class that serves as its optimistic lock value.

```
@Version
@Column(name="OPTLOCK")
protected int getVersionNum() { return versionNum; }
```

Defining Embeddable Class Mapping

Embeddable classes are simple Value type classes. Follow the instructions for defining Value type class mappings to define Embeddable class mapping for EJB 3.

In EJB 3, Embeddable classes can contain only attribute mappings, and these persistent attributes can have only basic types, i.e. Embeddable classes cannot contain nested Embeddable classes.

Note: The Embeddable class must implement the `java.io.Serializable` interface and overrides the `equals()` and `hashCode()` methods.

The Embeddable annotation is generated to specify a class whose instances are stored as an intrinsic part of an owning entity and share the identity of the entity.

```

@Embeddable
public class Address implements java.io.Serializable {
    @Basic(optional=true)
    @Column(name="address_country")
    public String getCountry() {}
    .....
}

```

Defining EJB 3 Association Mappings

EJB 3 persistence provides support for most of the association mapping strategies. We will just address the differences here.

One association must be defined between two Entity classes or one Entity class and one Mapped superclass before it can be mapped. Association mapping with a Mapped superclass as the target will be ignored. Embeddable classes can be either the source or the target of associations.

Mapping for associations with association class is not currently supported. You must separate each kind of associations into two equivalent associations.

For more informations about mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

Mapping One-to-one Associations

EJB 3 persistence supports both bi-directional one-to-one association mapping and unidirectional one-to-one association mapping.

The `OneToOne` annotation is generated to define a single-valued association to another entity that has one-to-one multiplicity. For bi-directional one-to-one associations, the generated annotations will resemble:

```

@OneToOne(cascade=CascadeType.ALL, fetch=FetchType.EAGER)
@JoinColumns({
    @JoinColumn(name="aid", referencedColumnName="aid")
})
public Account getAccount() { ... }

```

```
@OneToOne(cascade=CascadeType.PERSIST, mappedBy="account")
public Person getPerson() { ... }
```

Generated annotations for unidirectional one-to-one associations are similar. A model check is available to verify that mappings are correctly defined for unidirectional one-to-one associations. One unidirectional association can only be mapped to a reference that has the same direction as the association.

For more informations about mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

Mapping One-to-many Associations

EJB 3 persistence supports bi-directional one-to-many association mapping, unidirectional one-to-one association mapping and unidirectional one-to-many association mapping.

A `OneToMany` annotation is generated to define a many-valued association with one-to-many multiplicity. A `ManyToOne` annotation is generated to define a single-valued association to another entity class that has many-to-one multiplicity. The `JoinColumn` annotation is generated to specify a join column for the reference associating the tables. For bi-directional one-to-many associations, generated annotations will resemble:

```
@OneToMany(fetch=FetchType.EAGER, mappedBy="customer")
public java.util.Collection<Order> getOrder() { ... }
```

```
@ManyToOne
@JoinColumn({
    @JoinColumn(name="cid", referencedColumnName="cid")
})
public Customer getCustomer() { ... }
```

Generated annotations for unidirectional many-to-one associations are similar. A model check is available to verify that mappings for bi-directional one-to-many associations and unidirectional many-to-one associations are correctly defined. The references can only navigate from primary tables of classes on the multiple-valued side to primary tables of classes on the single-valued side.

For unidirectional one-to-many association, the `JoinTable` annotation is generated to define middle table and join columns for the two reference keys.

```
@OneToMany(fetch=FetchType.EAGER)
@JoinTable(
    name="Customer_Order",
    joinColumns={
        @JoinColumn(name="cid", referencedColumnName="cid")
    },
    inverseJoinColumns={
        @JoinColumn(name="oid",
            referencedColumnName="orderId")
    }
)
public java.util.Collection<Order> getOrder() { ... }
```

A model check is available to verify that mappings for unidirectional one-to-many associations are correctly defined. Middle tables are needed for this kind of one-to-many association mapping.

One-to-many associations where the primary key is migrated are not supported in EJB 3.

For more informations about mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

Mapping Many-to-many Associations

EJB 3 persistence supports both bi-directional many-to-many association mapping and unidirectional many-to-many association mapping.

A ManyToMany annotation is generated to define a many-valued association with many-to-many multiplicity.

```
@ManyToMany(fetch=FetchType.EAGER)
@JoinTable(
    name="Assignment",
    joinColumns={
        @JoinColumn(name="eid", referencedColumnName="eid")
    },
    inverseJoinColumns={
        @JoinColumn(name="tid", referencedColumnName="tid")
    }
)
public java.util.Collection<Title> getTitle() { ... }
```

A model check is available to verify that mappings are correctly defined for many-to-many associations. Middle tables are needed for many-to-many association mapping.

For more informations about mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

Defining EJB 3 Association Mapping Options

The following EJB 3-specific options for association mappings are available on the EJB 3 Persistence tab of an association's property sheet:

Field	Description
Inverse side	Specifies which side is the inverse side.
Role A cascade	Specifies which cascade operation can be performed on role A side.
Role B cascade	Specifies which cascade operation can be performed on role B side.
Role A fetch	Specifies if role A side should be fetched eagerly.
Role B fetch	Specifies if role B side should be fetched eagerly.
Role A order by	Specifies the order clause for role A side.
Role B order by	Specifies the order clause for role B side.

Defining EJB 3 Inheritance Mappings

EJB 3 persistence supports all three popular inheritance mapping strategies and also mixed strategies.

- Table per class hierarchy - SINGLE_TABLE
- Joined subclass - JOINED
- Table per concrete class - TABLE_PER_CLASS

All classes in the class hierarchy should be either Entity classes or Mapped superclasses. For each class hierarchy, the primary identifier must be defined on the Entity class that is the root of the hierarchy or on a mapped superclass of the hierarchy.

You can optionally define a Version attribute on the entity that is the root of the entity hierarchy or on a Mapped superclass of the entity hierarchy.

Mapped Superclasses

In EJB 3.0, Mapped superclasses are used to define state and mapping information that is common to multiple entity classes. They are not mapped to separate tables of their own. You cannot currently define Mapped superclasses in PowerDesigner.

Table Per Class Hierarchy Strategy

In this strategy, the whole class hierarchy is mapped to one table. You can optionally define discriminator values for each Entity class in the hierarchy on the EJB 3 Persistence tab of the class property sheet.

Option	Description
Discriminator value	Specifies a value that distinguishes individual this class from other classes.

The Inheritance annotation with SINGLE_TABLE strategy is generated. The DiscriminatorColumn annotation is generated to define the discriminator column. The DiscriminatorValue annotation is generated to specify the value of the discriminator column for entities of the given type if you specify it for the class.

For more informations about mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

```
@Entity(name="Shape")
@Inheritance(strategy=InheritanceType.SINGLE_TABLE)
@DiscriminatorColumn(name="shapeType",
discriminatorType=DiscriminatorType.STRING, length=100)
@Table(name="Shape")
public class Shape { ... }

@Entity(name="Rectangle")
@Inheritance(strategy=InheritanceType.SINGLE_TABLE)
@DiscriminatorValue("Rectangle")
```

```
@Table(name="Shape")
public class Rectangle extends Shape { ... }
```

A model check is available to verify that discriminator columns are correctly defined.

Joined Subclass Strategy

In this strategy, each class is mapped to its own primary table. Primary tables of child classes have reference keys referring to the primary tables of the parent classes.

An Inheritance annotation with JOINED strategy is generated. The PrimaryKeyJoinColumn annotation is generated to define a join column that joins the primary table of an Entity subclass to the primary table of its superclass.

For more informations about mapping, see *Chapter 23, Object/Relational (O/R) Mapping* on page 573.

```
@Entity(name="Shape")
@Inheritance(strategy=InheritanceType.JOINED)
@DiscriminatorColumn(name="shapeType")
@Table(name="Shape")
public class Shape { ... }

@Entity(name="Rectangle")
@Inheritance(strategy=InheritanceType.JOINED)
@PrimaryKeyJoinColumns({
    @PrimaryKeyJoinColumn(name="sid", referencedColumnName="sid")
})
@Table(name="Rectangle")
public class Rectangle extends Shape { ... }
```

A model check is available to verify that primary tables of child classes have reference keys referring to the primary tables of their parent classes.

Applying Table Per Class Strategy

In this strategy, each class is mapped to a separate table. When transforming an OOM to a PDM, PowerDesigner only generates tables for leaf classes, and assumes that all other classes are not mapped to a table, even if you manually define additional mappings. The MappedSuperclass annotations are generated for those classes, and the Inheritance annotation will not be generated for all the classes. You need to customize the generated annotations and create additional tables if you want to map classes other than leaf classes to tables.

```
@MappedSuperclass
public class Shape { .. }

@Entity(name="Rectangle")
@Table(name="Rectangle")
public class Rectangle extends Shape { ... }
```

Defining EJB 3 Persistence Default Options

The following default persistent options can be set at the model, package or class level:

Option	Description
Default access	Specifies an access strategy.
Mapping definition type	Specifies the level of mapping metadata to be generated.
Catalog name	Specifies the catalog name for persistent classes.
Schema name	Specifies the schema name for persistent classes.

Defining EJB 3 Persistence Configuration

There are some persistence properties which are used for database connection. You need to set them before run the generated application.

1. Open EJB 3 Persistence Configuration form from the model's property sheet.

The screenshot shows the 'EJB 3 Persistence' configuration window. The 'Persistence provider' is set to 'Hibernate' and the 'Transaction type' is 'RESOURCE_LOCAL'. The 'Data source' field is empty, and the 'Add Dali support' checkbox is unchecked. Under 'Database connection options', the 'JDBC driver class' is 'com.sybase.jdbc2.jdbc.SybDriver', the 'Connection URL' is 'jdbc:sybase:Tds:localhost:5000/orders', the 'JDBC driver Jar' is 'c:/Sybase/ASE/java/lib/jconn2.jar', the 'User name' is 'sa', and the 'Password' field is empty. Under 'Global options', the 'Cascade persist' checkbox is unchecked, and the 'Access strategy', 'Mapping definition type', 'Catalog', and 'Schema' fields are empty.

2. Select persistence provider you use. You should refer to compliance issues for some constraints with these persistence providers.
3. 3. Define JDBC driver class, connection URL, JDBC driver jar file path, user name and password.

Option	Description
Persistence provider	Specifies the persistence provider to be used.
Transaction type	Specifies the transaction type to be used.
Data source	Specifies the data source name (if data source is used).
Add Dali support	Specifies that the generated project can be authored in Dali. A special Eclipse project builder and nature will be generated.
JDBC driver class	Specifies the JDBC driver class.
Connection URL	Specifies the JDBC connection URL string.
JDBC driver jar	Specifies the JDBC driver jar file path.
User name	Specifies the database user name.
Password	Specifies the database user password.
Cascade persist	Specifies whether to set the cascade style to PERSIST for all relationships in the persistent unit.

You can verify the configuration parameters in the Preview tab. The generated persistence configuration file looks like:

```
<persistence xmlns="http://java.sun.com/xml/ns/persistence"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/persistence
http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd"
version="1.0">
  <persistence-unit name="EJB3_0Model" transaction-
type="RESOURCE_LOCAL">
    <description>
      This is auto generated configuration for persistent unit
      EJB3_0Model
    </description>
  <provider>org.hibernate.ejb.HibernatePersistence</provider>
  <!-- mapped files -->
  <!-- jar-file/-->
  <!-- mapped classes -->
  <class>com.company.orders.Customer</class>
  <class>com.company.orders.Order</class>
  <properties>
    <property
name="hibernate.dialect">org.hibernate.dialect.SybaseDialect</
```

```
property>
  <property
name="hibernate.connection.driver_class">com.sybase.jdbc2.jdbc.Sybd
river</property>
  <property
name="hibernate.connection.url">jdbc:sybase:Tds:localhost:5000/
Production</property>
  <property name="hibernate.connection.username">sa</property>
  <property name="hibernate.connection.password"></property>
  </properties>
</persistence-unit>
</persistence>
```

Checking the Model

To keep the model and mappings correct and consistent, you need to run a model check. If there are errors, you need to fix them. You can also run model checking before code generation.

Generating Code for EJB 3 Persistence

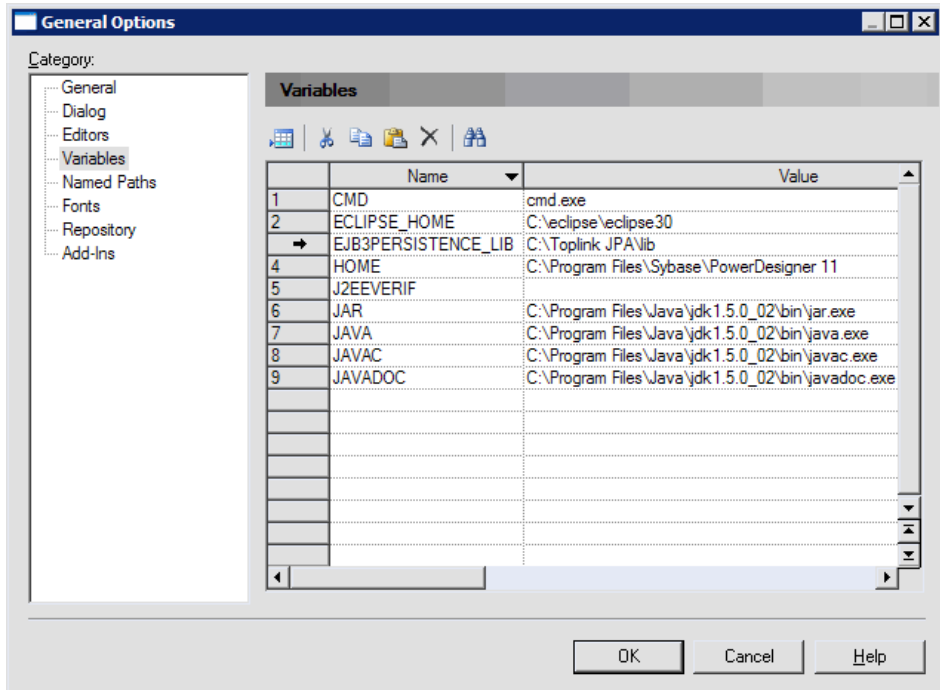

In order to generate code for EJB 3 persistence, you must.

- Download an EJB 3 persistence provider such as Hibernate Entity Manager, Kodo, TopLink and GlassFish.
- Define an environment variable to specify the location of the persistence library directory.
- Generate code - define model selection and generation options and preview generated file list.
- Run unit test.

Defining the Environment Variable

PowerDesigner uses an environment variable to generate library configuration for Eclipse project or Ant build script.

1. Select Tools > > **Generation Options**
2. Select the Variables node

3. Add a variable `EJB3PERSISTENCE_LIB` and, in the value field, enter directory path which you put your persistence provider libraries, for example `D:\EJB 3.0\Hibernate Entity Manager\lib`.

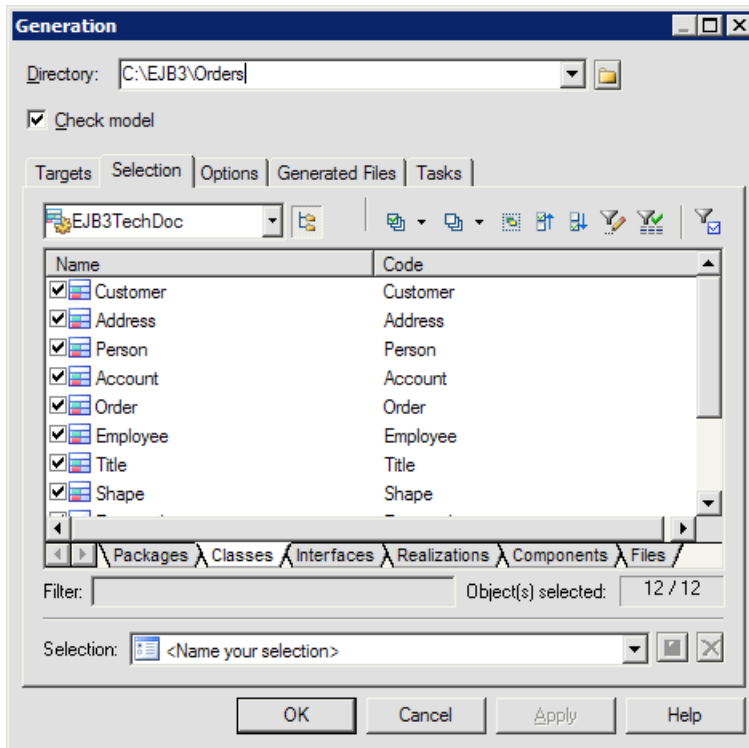

You can also define this as a Windows system environment variable, but you need to restart PowerDesigner to have it take effect.

Generate Code

To generate code, select **Language > Generate Java code** (Ctrl + G). Specify the directory where you want to put your generated code. On the Targets tab, make sure the O/R Mapping target is selected.

Select Model Elements

Select model elements to be generated on the Selection tab. The model should be selected for there are some important artifacts generated on the model level, such as persistence configuration file, DAO factory classes, DAO base classes etc.

Define Generation Options

- Define generation options on the Options tab.

Option	Description
Generate DAO sources	Specifies whether DAO sources should be generated.
Generate Eclipse project artifacts	Specifies whether Eclipse project file and classpath file should be generated.
Generate unit test sources	Specifies whether unit test sources should be generated.
Java source directory	Specifies directory for Java sources.
Test source directory	Specifies directory for unit test sources.
Generate schema validation files	Specifies whether schema file and validation script should be generated.
Generate Ant build.xml file	Specifies whether Ant build.xml file should be generated.

Preview Generated File List

You can get a preview of generated file list on the Generated files tab.

Specify Post Generation Tasks

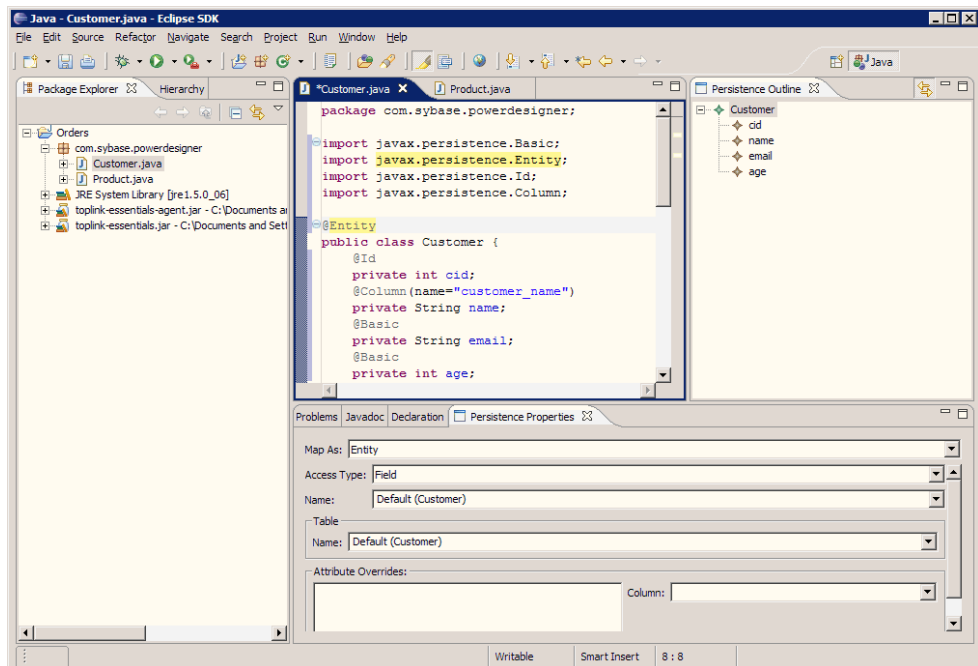

There are some tasks that can be run after the generation. You can select them on Tasks tab. The useful one is Run generated unit tests. PowerDesigner will run unit tests by Ant script generated after generation if you select the task. You can also run it on the command window. There are some prerequisites before you can run the task. We will show you how to run unit tests in the coming section.

Authoring in Dali Tools

Dali JPA tools provide support for the definition, editing, and deployment of Object-Relational (O/R) mappings for EJB 3.0 Entity Beans. It simplifies mapping definition and editing through:

- Creation and automated mapping wizards
- Intelligent mapping assistance
- Dynamic problem identification

You can import generated Eclipse project and do further editing in Dali tools if you had selected Add Dali support in model's property sheet.

Run Unit Tests

There are two ways you can run unit tests generated. One is running Ant task. The other is running them in Eclipse.

Running Unit Tests with Ant

To generate the Ant build.xml file, you need to select the Generate Ant build.xml file in the Java code generation options tab.

To use Ant, you need to:

- Download Ant from <http://www.apache.org> and install it.
- Define an environment variable ANT_HOME and set it to your Ant installation directory.
- Download junit-3.8.1.jar if you don't have it.
- Copy junit-3.8.1.jar to \$ANT_HOME/lib directory.
- Make sure that you have defined database connection parameters and JDBC driver jar correctly.

Running Unit Tests with Ant from PowerDesigner

You can run unit tests with Ant from PowerDesigner.

Select the Run unit tests task when generating code.

Running Unit Tests with Ant from the Command Line

You can run unit tests with Ant from the command line.

1. Open a command line window.
2. Go to the directory where you have generated the code.
3. Run the JUnit test task by issuing command: Ant junit
4. Check the output result in ejb3-persistence.log and testout directory.

Running Unit Test in Eclipse

To use Eclipse, you need to download and install the Eclipse SDK.

If you have selected the Generate Eclipse project artifacts generation option, you can import the generated project into Eclipse and use Eclipse to modify, compile and run the tests.

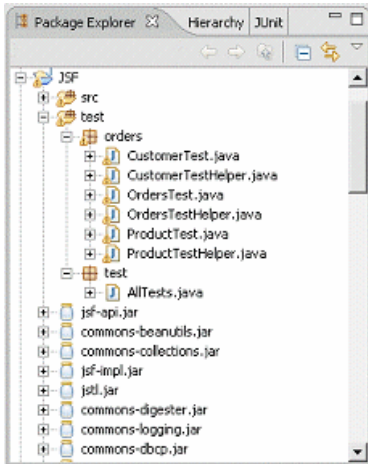

If you use the PowerDesigner Eclipse plugin, after the code generation, the project is automatically imported or refreshed in Eclipse.

You can run a single test case each time or run them as suite.

Running a Single Test Case

You can run a single test case.

1. Open the Java perspective
2. In the Package Navigator, expand the test package

3. Select a test case class, for example CustomerTest.java and run it as Unit Test
4. Select the JUnit view to verify the result:

Running the Test Suite

You can run test cases as a suite.

1. Select AllTests class under test package.
2. Run it as Application. All the tests will be run as suite.

Generated File List

The following files are generated:

- Eclipse Project Files - If you have selected the Generate Eclipse project artifacts generation option, .project file and .classpath file are generated by PowerDesigner. But if you are regenerating codes, these two files will not be generated again.
- Persistent Java Classes - If mapping definition type specified includes Annotation, Default, Annotation or Mapping File & Annotation, annotations will be generated in Java sources.
- Primary Key Classes - Primary key classes are generated to ease find-by-primary-key operation. It is also mandatory for composite primary key.
- EJB 3 Configuration File - The EJB 3 persistence configuration file persistence.xml is generated in META-INFO sub directory of Java source directory.
- Log4J Configuration File - PowerDesigner uses Log4j as the default logging framework to log messages. The Log4j properties file log4j.properties is generated in Java source directory.
- Utility Class - The Util.java class contains some utility functions that are used by unit tests, such as compare date by precision. It is defined in the com.sybase.orm.util package.
- EJB 3 O/R Mapping Files - If mapping definition type specified includes mapping file, Mapping File & Annotation or Mapping file, EJB 3 O/R mapping files will be generated. These mapping files are generated in the same directory with Java source.
- Factory and Data Access Objects - To help simplify the development of your application, PowerDesigner generates DAO Factory and Data Access Objects (DAO), using Factory and DAO design pattern.
- Unit Test Classes - generated to help user perform test to prove that:
 - The mappings are correctly defined
 - The CRUD (Create, Read, Update and Delete) work properly
 - The find methods work
 - The navigations work

Unit test classes include:

- Test helper classes - provide some utility functions for unit test classes, such as creating new instances, modifying state of instances, saving instances etc.
- Unit Test Classes - For each persistent entity, PowerDesigner generates a unit test class. The generated test cases are:
 - Insert test method - to test instance insert.
 - Update test method - to test instance update.
 - Delete test method - to test instance delete.
 - Property finder test methods - to test every property finder method defined in Dao.
 - Get all instance list test method - to test get all instances method.
 - Navigation test method - to test association mapping.
 - Inheritance test method - to test inheritance mapping.

- User defined operation test methods - skeleton test methods for user defined functions.
- AllTest Class - a test suite that runs all the unit test cases.
- Ant Build File - PowerDesigner can generate an Ant build file to help you to compile and run unit tests if you set the Generate Ant build.xml file option to true in the Java code generation window. The Ant build.xml contains customized elements for EJB 3:
 - Custom properties - that specify directories and class path.
 - Custom target definitions - to define JUnit tasks.
 - Custom tasks - to run JUnit test or generate JUnit test reports.

Generating JavaServer Faces (JSF) for Hibernate

JavaServer Faces (JSF) is a UI framework for Java Web applications. It is designed to significantly ease the burden of writing and maintaining applications that run on a Java application server and render their UIs back to a target client.

PowerDesigner can generate JSF pages automatically according to the O/R mapping persistent framework you select, such as Hibernate or EJB3.0. You can quickly build Web application without writing repeated code because PowerDesigner generates persistent classes, DAO, managed beans, page navigation and JSF pages.

JSF generation can help you to test persistent objects using Web pages with your own data.

JSF generation can also help you to generate default JSF Web application. You can use an IDE to improve the generated JSF pages or change the layout.

Adding JSF Support

PowerDesigner provide an extended model definition to support JSF extended attributes, model checks, JSP templates, invoker-managed bean templates, and face-configure templates.

1. Verify that the current model has the target language Java or Java 1.x
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **User Interface** tab, select the `JavaServer Faces (JSF) xem`, and click **OK** to attach it to your model.
4. Click **OK** to close the List of Extended Model Definitions and return to your model.

Note that, as JSF uses Data Access Objects (DAO) to access data from the database, you will need also to add a persistence management Extended Model Definition such as Hibernate in order to generate JSF.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

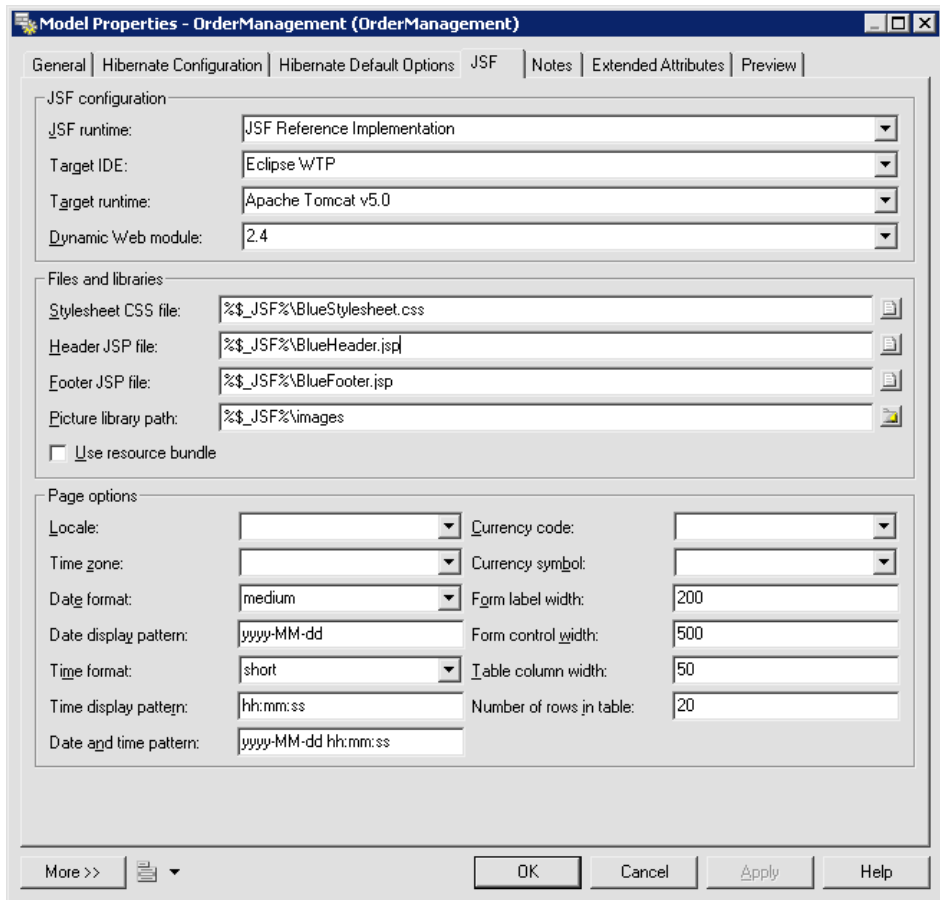

Defining Global Options

Each page could use a style sheet, a header file and a footer file to define its standard presentation.

PowerDesigner provides default style sheet, header and footer files. Alternatively, you can specify your own files.

You can also define global default options like data format, time format, etc.

1. Open the model property sheet, and click the JSF tab:

2. Define style sheet, header and footer files.
3. Define the directory where the images used by style sheet, header and footer.
4. Define the JSF library Jar files directory.
5. Define default options.

The following options are available:

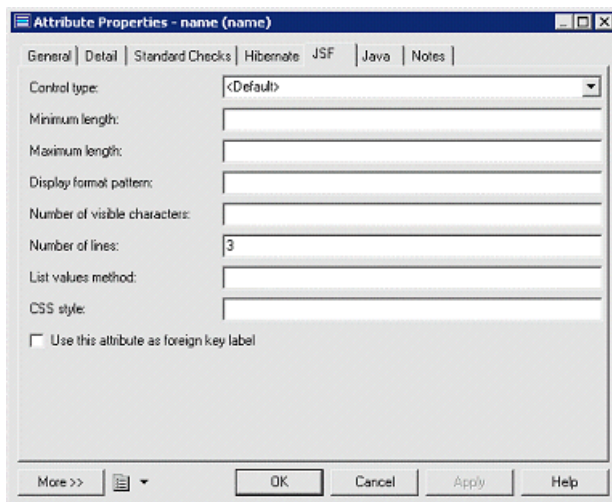

Option	Description
JSF runtime	Specifies the JSF runtime. It can be JSF Reference Implementation or Apache My Faces.
Target IDE	Specifies the target IDE. List/Default Values: Eclipse WTP, Sybase WorkSpace
Target runtime	Specifies the target runtime. List/Default Values: Apache Tomcat v5.0, Sybase EAServer v5.x, etc.
Dynamic Web Module	Specifies the dynamic web module's version List/Default Values: 2.2, 2.3, and 2.4.
Stylesheet CSS File	Specifies the stylesheet file for JSF pages. List/Default Values: %\$_JSF%\stylesheet.css
Header JSP file	Specifies the header file for JSF pages. List/Default Values: %\$_JSF%\header.jsp
Footer JSP file	Specifies the footer file for JSF pages. List/Default Values: %\$_JSF%\footer.jsp
Picture library path	Specifies the path that contains pictures for JSF pages. List/Default Values: %\$_JSF%\images
Use resource bundle	Specifies to use a resource bundle.
Locale	Specifies the locale
Time zone	Specifies the time zone
Date format	Specifies the date format could be default, short, medium, long, full Default: short
Date display pattern	Specifies the date pattern
Time format	Specifies the date format could be default, short, medium, long, full Default: short
Time display pattern	Specifies the time pattern
Date and time pattern	Specifies the date and time pattern
Currency code	Specifies the currency code

Option	Description
Currency symbol	Specifies the currency symbol
Form label width	Specifies the width of the control label in pixel in a form Default: 200
Form control width	Specifies the width of the control in pixel in a form Default: 500
Table column width	Specifies the width of the control in pixel in a table Default: 50
Table number rows	Specifies the number of rows that can be displayed in a table Default: 20

Defining Attribute Options

You can define attribute-level options for validation or presentation style.

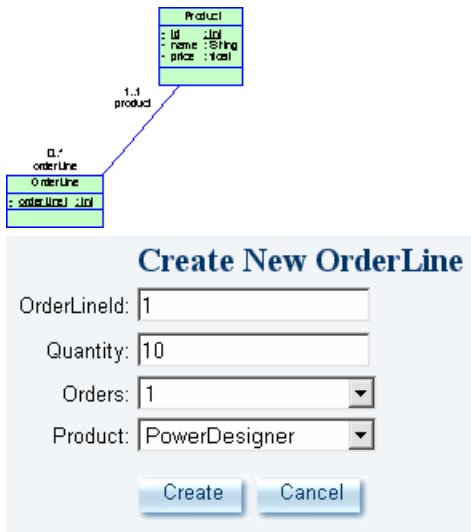

1. Open Attribute Property sheet, select JSF tab.
2. Define Attribute options.

Option	Description
Control type	<p>Specifies the type of control.</p> <p>Note: You should select the type that can support the Attribute Java type.</p> <ul style="list-style-type: none"> • String - EditBox, MultilineEdit • Boolean - CheckBox • Date - Date, Time, DateTime, Year, Month, Day • <Contains List of Value> - ListBox, ComboBox, RadioButtons
Minimum length	Specifies the minimum number of characters
Maximum length	Specifies the maximum number of characters
Display format pattern	Specifies the display format pattern for the attribute
Number of visible characters	Specifies the number of visible characters per line
Number of lines	<p>Specifies the number of lines for multiline edit control</p> <p>Default: 3</p>
List values method	Specifies the method that provides the list of values for ListBox, ComboBox or radioButtons.
CSS style	Specifies the CSS formatting style
Use the attribute as foreign key label	<p>Specifies that the column associated to the attribute will be used as the foreign key label for the foreign key selection.</p> <p>If no FK label column is defined, PowerDesigner will choose the first not-PK and non FK column for the default label column.</p> <p>Default: False</p>

Note: If the "Use the attribute as foreign key label" checkbox is not selected and if there is a foreign key in the current table, PowerDesigner generates a combo box by default to display the foreign key id. If you want to display the value of another column (for example, the product name instead of the product id), you can select the "Use the attribute as foreign key label" option for product name attribute to indicate that it will be used as foreign key label.

Remember that if some attributes specify the choice to be true, we will generate the foreign key label only according to the first attribute of them.

Derived Attributes

To support derived attributes in PowerDesigner, you can:

1. Define an attribute, and indicate that it is not persistent, and is derived.
2. Generate and implement a getter.

When generating pages, PowerDesigner will automatically include the derived attributes.

Attribute Validation Rules and Default Values

PowerDesigner can generate validation and default values for the edit boxes in the Create and Edit pages.

1. Open the attribute property sheet, and click the Standard Checks tab.
2. You can define minimum value and maximum values to control the value range.
3. You can define a default value. A string, must be enclosed in quotes. You can also define the Initial value in the Details tab.
4. You can define a list of values that will be used in a listbox, combo box or radio buttons.

Note: You can set a "list of values" on the Standard Checks tab of an attribute property sheet, and PowerDesigner will generate a combo box that includes the values. For validation rules, you can define the customized domain as well, and then select the domain you want to apply in the specified attribute.

You can also select which control style to use:

- Combobox
- Listbox

- Radio buttons (if the number of values is low) For example: Mr. Ms.

Defining Master-Detail Pages

If two objects have a master-detail relationship, PowerDesigner renders them (create, update, delete and find methods) in the same page. When you click the detail link button column in the master table view, the detail page view in the same page will change dynamically.

For example, there is a table Orders (Master table) and a table Orderline (Detail table). The association is a composition. If you delete an order, the order lines should be deleted. They will be shown on the same page:

1. Create a one-to-many association, where the one-to-many direction is navigable.
2. Open the association property sheet, and click the JSF tab.
3. Select the "Use Master-Detail Page" checkbox:

The association type must be set to Composition or Aggregation, which means that one side of association is a weak-reference to the master class.

The generated master-detail JSF page will resemble the following:

Orders List

Id	Date	Total	Customer	OrderLines	Edit	Delete
16	Jan 1, 2005	3000.0	Customer	OrderLines	Edit	Delete

[Create](#) [Cancel](#)

OrderLine List

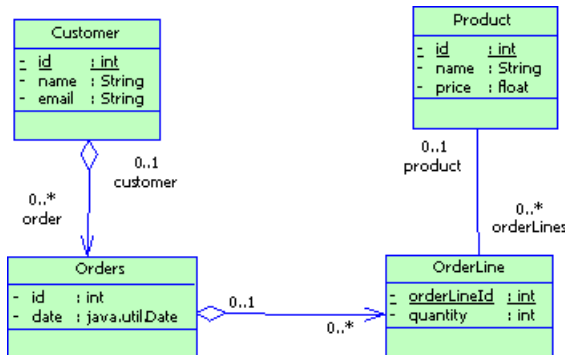

OrderLineId	Quantity	Order	Product	Edit	Delete
1	10	Order	Product	Edit	Delete
2	5	Order	Product	Edit	Delete
4	1	Order	Product	Edit	Delete
5	2	Order	Product	Edit	Delete

[Create](#) [Cancel](#)

Generating PageFlow Diagrams

In Java Server Faces, a configuration (xml) file is used to define navigation rules between different web pages, which is called PageFlow. Power Designer will provide a high level PageFlow diagram to abstract different kinds of definition, and can generate navigation rules for JSF web application and JSF page bean based on PageFlow diagram.

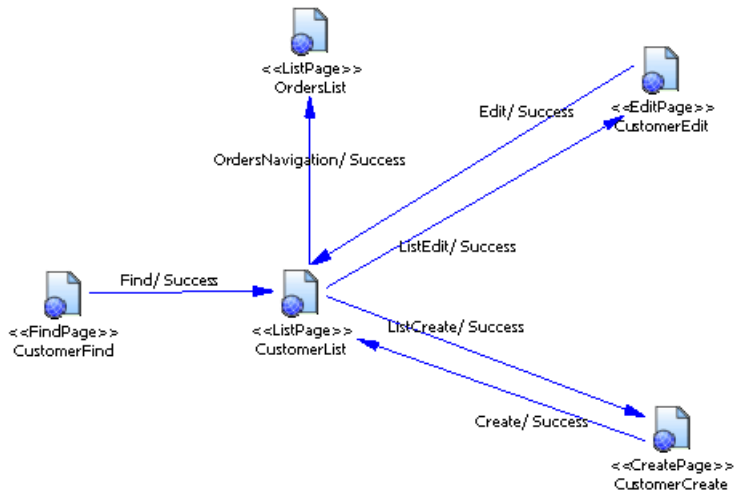

You can Generate PageFlow Diagram diagram in three levels, Model, Package and Class. Next description will use the following example.

Generating a class level PageFlow diagram

You generate a class level PageFlow diagram as follows:

1. Select one class in the ClassDiagram, e.g., Customer. Right click and select the context menu "Generate PageFlow Diagram".
2. A new PageFlow will be automatically generated, e.g., CustomerPageFlow.

Generating a Package Level PageFlow Diagram:

You generate a package level PageFlow diagram as follows:

1. Select one package, e.g., "Orders". Right click it and select the context menu "Generate PageFlow Diagram".
2. The PageFlow will be generated for each class under this package and its sub packages recursively, e.g., CustomerPageFlow, OrdersPageFlow, ProductPageFlow, OrderLinePageFlow.

Generating a Model Level PageFlow Diagram

You generate a model level PageFlow diagram as follows:

1. Right click on the model, e.g., "JSF", and select the context menu "Generate PageFlow Diagram".
2. A model level PageFlow will be generated, e.g., "JSFPageFlow" automatically. At the same time, the PageFlow will be generated for each class under this package and its sub packages recursively, e.g., CustomerPageFlow, OrdersPageFlow, ProductPageFlow, OrderLinePageFlow.

Modifying Default High Level PageFlow Diagram

After generating the default High Level PageFlow, you can define customized pages and pageflows in the class level PageFlow.

All the pages in the default High Level PageFlow diagram have their pre-defined stereotype, e.g., The stereotype for CustomerFind is "FindPage", CustomerEdit is "EditPage", etc. You can add your customized Page.

You can also add new PageFlows to link the pages in the PageFlow diagram, which is similar to adding a transition in a statechart diagram.

Adding a New Page:

You add a new page as follows:

1. Select the "State" from the palette, and drag it to the PageFlow diagram, it will create a new Page with the default name.
2. You can change its name and change its stereotype to Page in its property dialog, e.g., change the name to "Home". This dialog is same with general State.

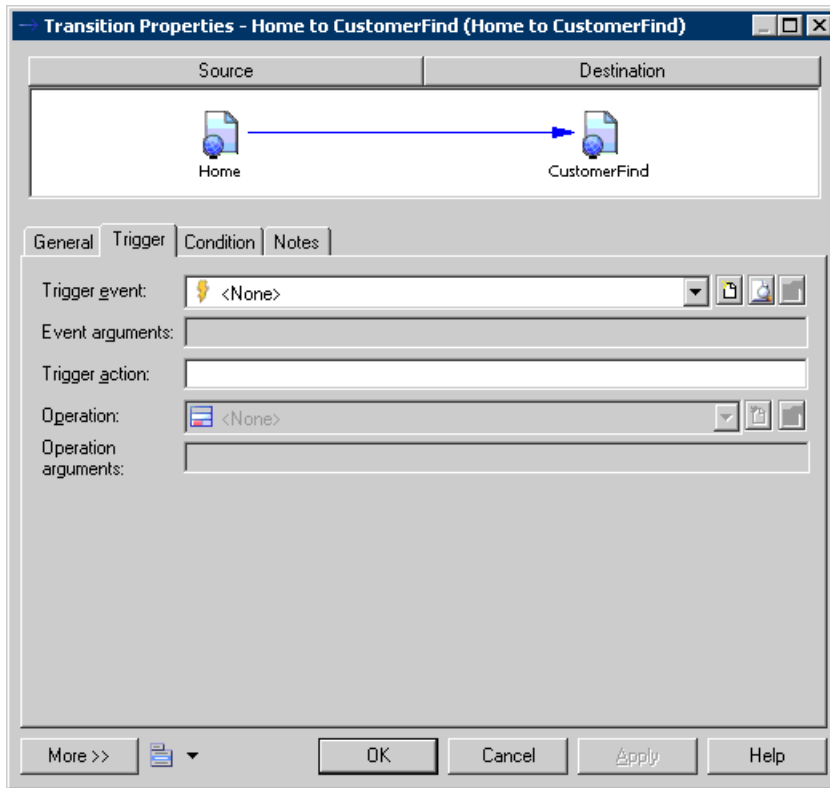

After create a new Page, when the code generation, a default JSF page and its page bean will be generated.

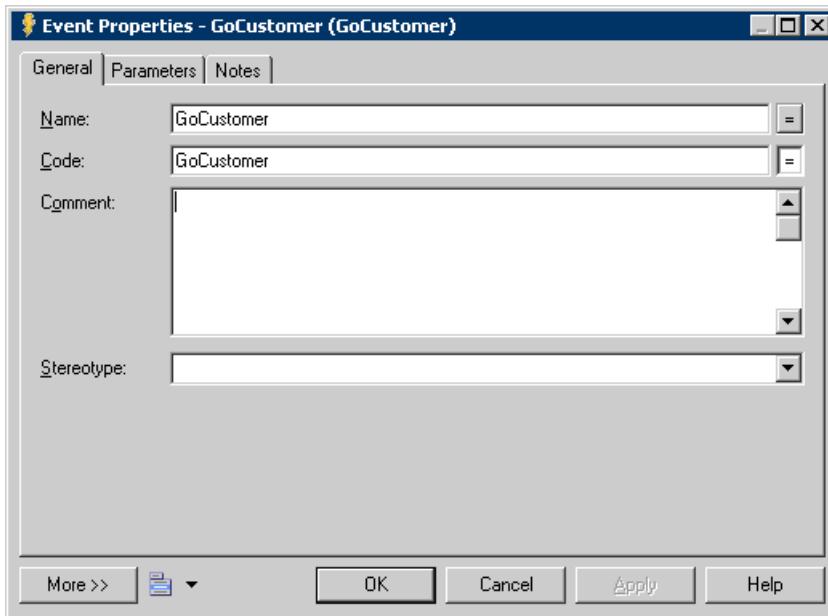

Adding a New PageFlow

You add a new PageFlow as follows:

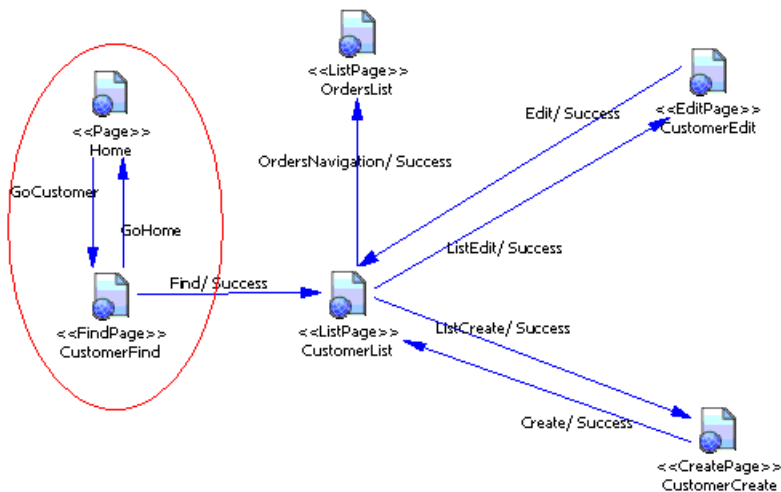

1. Select "Transition" from Palette
2. Select the source state, e.g., "Home", to the target state, e.g., "CustomerFind". A default transition will be generated.
3. Double click the default transition, or right click the default transition and select the context menu "Properties", its property dialog will pop up.

1. Click "Create" button beside "Trigger Event" list, it will pop up Trigger Event creation dialog. You can input the name, e.g., GoCustomer. Click "OK" to finish the creation of Trigger Event.

1. Click "OK" in the property dialog of Transition. A new PageFlow will be created.

After you modify the default pageflow, and generate JSF codes, the corresponding default JSF pages, page beans and faces-config file will be updated.

Installing JSF Runtime Jar Files

You can use an IDE like Eclipse WTP or Sybase WorkSpace to edit, deploy and test JSF pages.

If the IDE does not include JSF runtime Jar files, you will need to download a copy and install them.

You can use the following JSF runtimes:

JSF reference implementation

Apache My Faces

Installing the JSF Reference Implementation

You install the JSF Reference Implementation as follows:

1. Download the JSF reference implementation from the Sun JavaServer Faces website:
<http://java.sun.com/javaee/javaserverfaces/>
2. Unzip the downloaded file into a folder. This folder contains the required library files:
 - commons-beanutils.jar
 - commons-collections.jar
 - commons-digester.jar
 - commons-logging.jar
 - jsf-api.jar
 - jsf-impl.jar
3. The JSF reference implementation requires an additional jar file:
 - jstl.jar

You can download it from the Apache Jakarta Project website: <http://jakarta.apache.org/>.

Unzip the downloaded file to obtain the folder "jakarta-taglibs\standard\lib", and copy the jstl.jar file to the JSF reference implementation lib folder.

4. Define a "JSF_LIB" variable in the PowerDesigner "General Options" window, Variables tab to indicate the JSF reference implementation lib folder path.

Installing Apache My Faces

You install Apache My Faces as follows:

1. Download the Apache MyFaces JSF implementation from the Apache MyFaces Project website: <http://myfaces.apache.org/>

Select the current release of Apache MyFaces, for example, myfaces-1.1.1.zip.

2. Download the current release of Apache MyFaces, and unzip it into a folder, which will contain the following jar files:

- myfaces-all.jar
- myfaces-api.jar
- myfaces-impl.jar

Remove the myfaces-api.jar and myfaces-impl.jar files.

3. Download the dependency jar files from the same site and copy the jar files of the folder myfaces-blank-example\WEB-INF\lib to the Apache MyFaces lib folder. You should have the following jar files:
 - commons-beanutils-1.6.1.jar
 - commons-codec-1.2.jar
 - commons-collections-3.0.jar
 - commons-digester-1.5.jar
 - commons-el.jar
 - commons-logging.jar
 - commons-validator.jar
 - log4j-1.2.8.jar
4. Define a "JSF_LIB" variable in the PowerDesigner "General Options" window, Variables tab to indicate the Apache MyFaces implementation lib folder path.

Configuring for JSF Generation

You configure for JSF generation as follows:

1. Select **Tools > General Options**.
2. Select the Variables Category.
3. Add a new row in the Variables list:
 - Name: JSF_LIB
 - Value: Select JSF Jar file library folder.
4. Select the Named Paths Category.
5. If there is no _JSF named path, add a new row in the Named Paths list:
 - Name: _JSF
 - Value: Select the JSF folder where it contains JSF style sheets, headers, footers and images.

Generating JSF Pages

Before generation, make sure that you have attached the Hibernate Extended Model Definition to the model, and checked the model for errors.

1. Java CodeSelect **Language > Generate Java Code**.
2. Specify a target directory.

3. Define generation options.
4. Click OK.

The generation produces the following files:

- Persistent files (persistent classes, DAO, ...)
- Eclipse and Eclipse WTP project artifacts
- A home page
- JSF pages for persistent classes
- Managed beans
- Page flows (face configuration files)

For each persistent class, PowerDesigner generates:

- A find page for searching objects
- A list page for displaying find results
- A create page for creating new objects
- An edit page for updating objects

Testing JSF Pages

You can deploy a JSF Web application in a Web server or an application server that supports JSP. For example, Apache Tomcat, JBoss.

You can use an IDE like Eclipse to edit the generated Java classes, and use the Eclipse WTP (Web Tools Project) to edit JSF pages and face config files.

Testing JSF Pages with Eclipse WTP

You test JSF Pages with Eclipse WTP as follows:

1. Install a Web server such as Tomcat or an application server such as JBoss.
2. Generate Java code
3. Import the JSF project into Eclipse. The project is built.
4. Configure your Web server or application server.
5. Start the database.
6. Start the Web server or application server using the WTP Servers view.
7. Right-click the index.jsp under the webroot folder and select **Run As > Run on Server**.
8. Select the server you want to use in the list.

Testing JSF Pages with Apache Tomcat

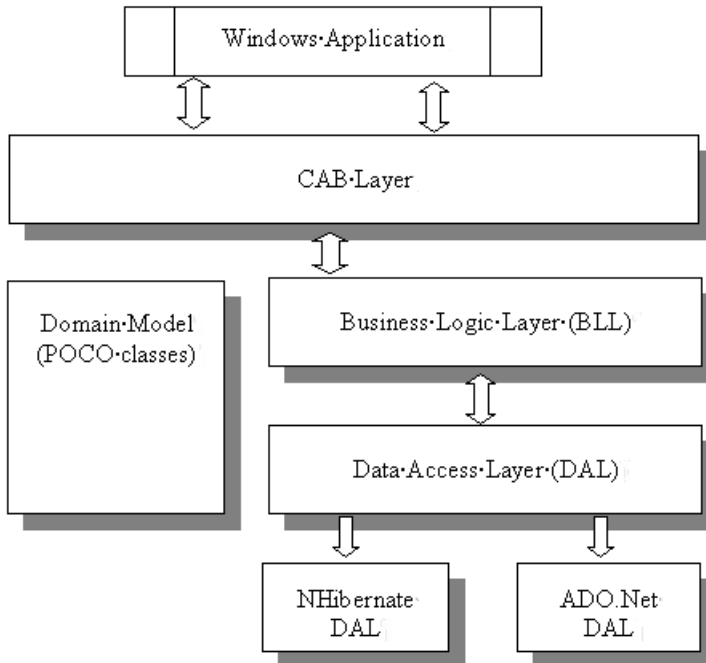

You test JSF Pages with Apache Tomcat as follows:

1. Install a Web server such as Tomcat or an application server such as JBoss.
2. Generate Java code

3. Import the JSF project into Eclipse. The project is built.
4. Copy the <ProjectName> folder under the .deployables folder into the Apache Tomcat webapps folder. Where <ProjectName> is the Eclipse project name.
5. Start the database.
6. Start Apache Tomcat server.
7. Run the Web application using the URL: `http://<hostname>:8080/<ProjectName>/index.jsp`. If Apache Tomcat is installed locally, <hostname> is localhost.

CHAPTER 25 Generating .NET 2.0 Persistent Objects and Windows Applications

PowerDesigner follows the best practices and design patterns to produce n-tier architecture enterprise applications for the .NET framework, as shown in the following figure:

PowerDesigner can be used to generate all these layers:

- Domain Model - contains persistent POCOs (Plain Old CLR Objects), which are similar to Java's POJOs. These act as information holders for the application and do not contain any business logic. A primary key class is generated for each persistent class in order to help the "find-by-primary-key" function, especially when the class has a composite primary identifier.
- Data Access Layer - follows the standard DAO pattern, and provides typical CRUD methods for each class. This layer is divided into two parts, one of which contains interfaces for DAL, while the other contains the implementation for these interfaces, using ADO.NET technology to access databases.

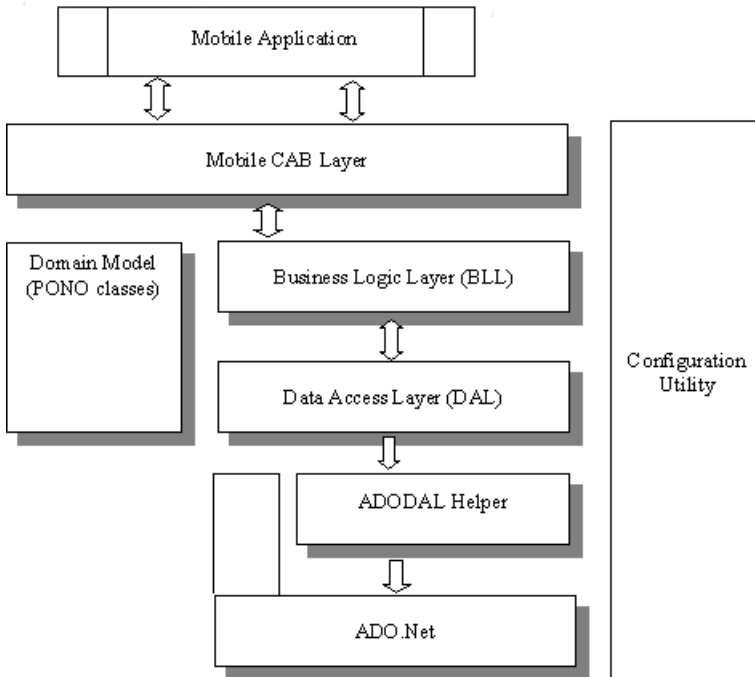

The DAL Helper provides common features used by all the DAL implementations, such as connection and transaction management, and the supply of SQL command parameters. Some common classes, such as Session, Criteria, and Exception, are also defined.

PowerDesigner supports two kinds of DAL implementation:

- ADO.NET (see *Generating ADO.NET and ADO.NET CF Persistent Objects* on page 669)
- Nhibernate (see *Generating Nhibernate Persistent Objects* on page 677)
- Business Logic Layer - contains the typical user-defined business logic. This is a wrapper for the DAL, exposing CRUD functionalities provided by the DAL underneath. You can customize this layer according to your needs.
- Windows Application - the Composite UI Application Block, or CAB layer helps you build complex user interface applications that run in Windows. It provides an architecture and implementation that assists with building applications by using the common patterns found in line-of-business client applications.

PowerDesigner can generate data-centric windows applications based on the CAB (see *Generating Windows or Smart Device Applications* on page 701).

The .NET CF (Compact Framework) has a similar organization, but with a configuration utility class that provides the capability to load and parse configuration used in different layers, e.g., data source configuration, log and exception configuration, etc:

PowerDesigner supports the ADO.NET DAL implementation for the .NET CF (see *Generating ADO.NET and ADO.NET CF Persistent Objects* on page 669)

Generating ADO.NET and ADO.NET CF Persistent Objects

Microsoft ADO.NET and ADO.NET CF are database-neutral APIs. PowerDesigner provides enhancements to them to support:

- Cascade Association: one-to-one, one-to-many, many-to-one, and complex many-to-many associations.
- Inheritance: table per class, table per subclass, and table per concrete class hierarchies.
- Value Types
- SQL statements: including complex SQL statement like Join according to OOM model and PDM model.

PowerDesigner also supports the design of .NET classes, database schema and Object/Relational mapping (O/R mapping), and can use these metadata, to generate ADO.NET and ADO.NET CF persistent objects including:

- Persistent .NET classes (POCOs)
- ADO.NET O/R mapping classes (ADODALHelper)
- DAL factory
- Data Access Objects (DAL)

Adding ADO.NET or ADO.NET CF Support

PowerDesigner provides support for ADO.NET and ADO.Net CF through extended model definitions.

1. Verify that the current model has the target language C# 2.0 or Visual Basic 2005.
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **O/R Mapping** sub-tab, select the ADO.NET or ADO.NET Compact Framework xem, and click **OK** to attach it to your model.
4. Click **OK** to close the List of Extended Model Definitions and return to your model.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

ADO.NET and ADO.NET CF Options

To set the database connection parameters and other ADO.NET or ADO.NET CF options, double-click the model name in the browser to open its property sheet, and click the ADO.NET or ADO.NET CF tab.

Option	Description
Target Device	[ADO.NET CF only] Specifies the operating system on which the application will be deployed.

Option	Description
Output file folder	[ADO.NET CF only] Specifies the location on the device to which the application will be deployed. Click the ellipsis button to the right of this field to edit the root location and add any appropriate sub-directories.
Data Provider	Specifies which data provider you want to use. For ADO.NET, you can choose between: <ul style="list-style-type: none"> • OleDb • SqlClient • ODBC • Oracle For ADO.NET CF, you can choose between: <ul style="list-style-type: none"> • Microsoft SQL Server 2005 Mobile Edition • Sybase ASA Mobile Edition
Connection String	Specifies the connection string. You can enter this by hand or click the ellipsis tool to the right of the field to use a custom dialog. For information about the provider-specific parameters used to build the connection string, see <i>Configuring Connection Strings</i> on page 693.
Default access	Specifies the default class attribute access type. This and the other package options, are valid for the whole model. You can fine-tune these options for an individual package through its property sheet.
Default cascade	Specifies the default cascade type.
Default command type	Specifies the default command type, which can be overridden by concrete class.
DALContainer	Specifies the collection type returned from database. You can choose between Generic List Collection and System.Collections.ArrayList.
Logging Type	[ADO.NET only] The common logging component is Log4Net, but you can reuse it as well if you have your own logging framework. By default, the value of logging type is Console type, but PowerDesigner also supports "None" or Log4Net

Class Mappings

There are two kinds of classes in ADO.NET and ADO.NET CF:

- Entity classes - have their own database identities, mapping files and life cycles
- Value type classes - depend on entity classes. Also known as component classes

Framework-specific class mapping options are defined on the ADO.NET or ADO.NET CF tab of the class property sheet:

Option	Description
Default cascade	Specifies the default cascade style.
Default access	Specifies the default access type (field or property)
Default command type	Specifies command type, currently we supply Text and StoreProcedure to users.
Lazy	Specifies that the class should be lazy fetching.
Abstract class	Specifies that the class is abstract.
Discriminator column	Specifies the discriminator column or formula for polymorphic behavior in a one table per hierarchy mapping strategy.
Discriminator value	Specifies a value that distinguishes individual subclasses, which are used for polymorphic behavior.
Discriminator type	Specifies the discriminator type.

Primary Identifier Mappings

Primary identifier mapping is mandatory in ADO.NET and ADO.NET CF. Primary identifiers of entity classes are mapped to primary keys of master tables in data sources. If not defined, a default primary identifier mapping will be generated, but this may not work properly.

Mapped classes must declare the primary key column of the database table. Most classes will also have a property holding the unique identifier of an instance.

There are three kinds of primary identifier mapping in ADO.NET and ADO.NET CF:

- Simple identifier mapping - When a primary key is attached to a single column, only one attribute in the primary identifier can be mapped. This kind of primary key can be generated automatically. You can define increment, identity, sequence, etc., on the corresponding column in PDM.
- Composite identifier mapping - If a primary key comprises more than one column, the primary identifier can have multiple attributes mapped to these columns. In some cases, the primary key column could also be the foreign key column. In the following example, the Assignment class has a primary identifier with three attributes: one basic type attribute and two migrated attributes:

- Component identifier mapping - For more convenience, a composite identifier can be implemented as a separate value type class. The primary identifier has just one attribute with the class type. The separate class should be defined as a value type class. Component class mapping will be generated then. In the example below, three name attributes are grouped into one separate class Name, which is mapped to the same table as the Person class.

Person	
- <<PropertyImplementation>>	name : Name
- <<PropertyImplementation>>	sex : System.Char
- <<PropertyImplementation>>	age : int
+ <<Property>>	name : Name
+ <<Property>>	sex : System.Char
+ <<Property>>	age : int

Name	
- <<PropertyImplementation>>	firstName : String
- <<PropertyImplementation>>	middleName : String
- <<PropertyImplementation>>	lastName : String
+ <<Property>>	firstName : String
+ <<Property>>	middleName : String
+ <<Property>>	lastName : String

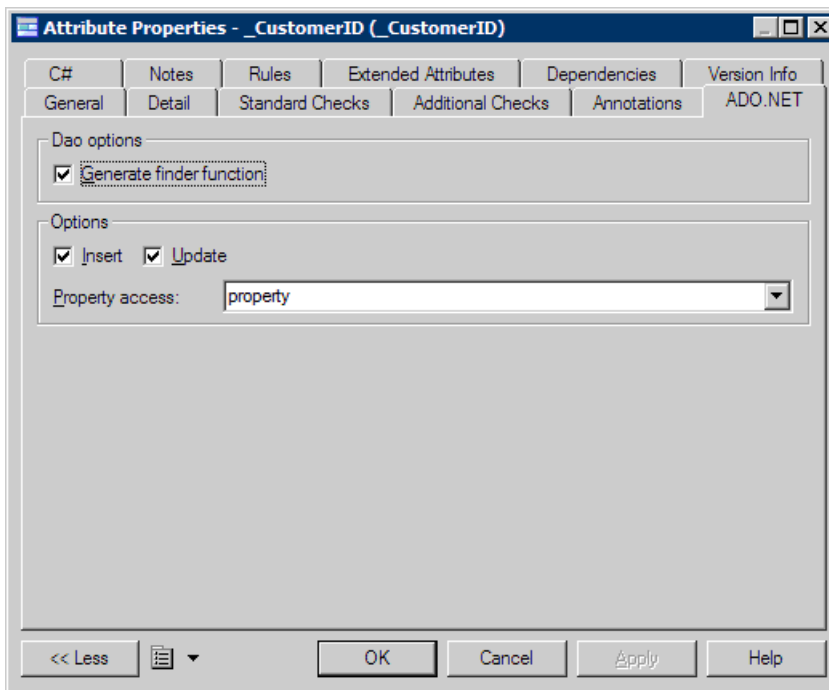

Attribute Mappings

Attributes can be migrated attributes or ordinary attributes. Ordinary attributes can be mapped to columns or formulas. Migrated attributes do not require attribute mapping.

The following types of mapping are possible:

- Component attribute mapping - A component class can define the attribute mapping as for other classes, except that there is no primary identifier.
- Discriminator mapping - In inheritance mapping with a one-table-per-hierarchy strategy, the discriminator needs to be specified in the root class. You can define the discriminator in the ADO.NET or ADO.NET CF tab of the class property sheet.

Framework-specific attribute mapping options are defined in the ADO.NET or ADO.NET CF tab of the Attribute property sheet.

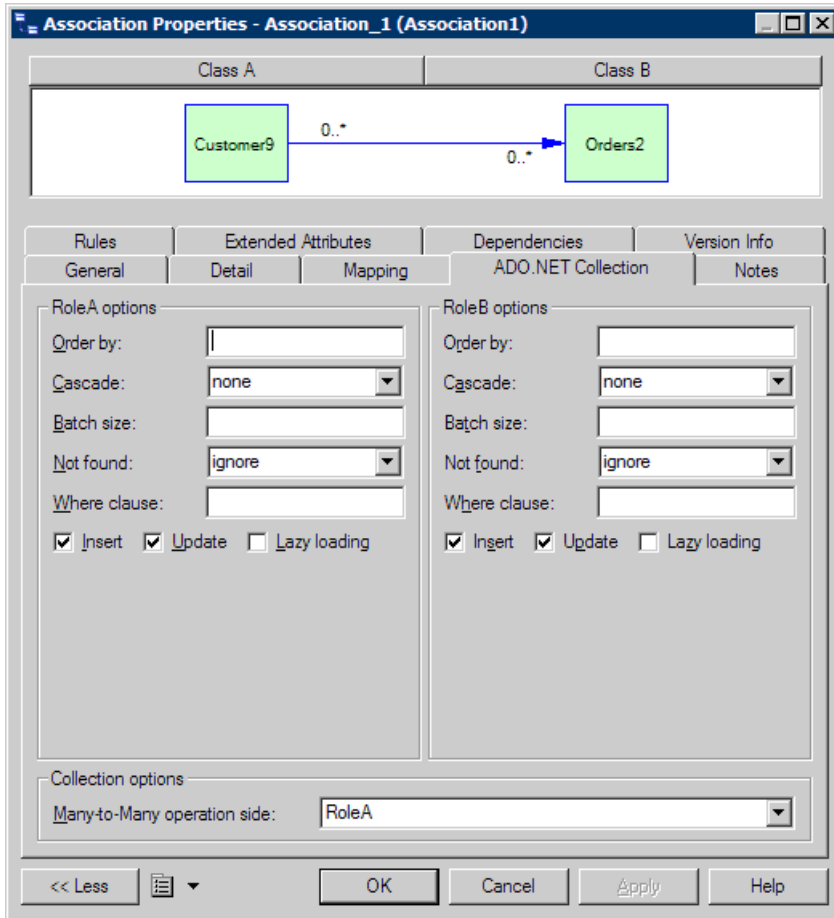

Option	Description
Generate finder function	Generates a finder function for the attribute.
Insert	Specifies that the mapped columns should be included in any SQL INSERT statements.
Update	Specifies that the mapped columns should be included in any SQL UPDATE statements.
Lazy	Specifies that this property should be fetched lazily when the instance variable is first accessed (requires build-time byte code instrumentation).
Property access	Specifies the strategy used for accessing the property value.

Defining Association Mappings

ADO.NET and ADO.NET CF support one-to-one, one-to-many/many-to-one, and many-to-many association mappings. PowerDesigner allows you to define standard association attributes like Container Type class, role navigability, array size and specific extended attributes for association mappings.

Open the Association property sheet and click the ADO.NET or ADO.NET CF Collection tab.

1. Define the appropriate options and then click OK.

The following options are available on this tab:

Option	Description
Order by	Specifies a table column (or columns) that define the iteration order of the Set or bag, together with an optional asc or desc.
Cascade	Specifies which operations should be cascaded from the parent object to the associated object.
Batch size	Specifies the batch load size.
Not found	Specifies how foreign keys that reference missing rows will be handled: ignore will treat a missing row as a null association.

Option	Description
Insert	Specifies that the mapped columns should be included in any SQL INSERT statements.
Update	Specifies that the mapped columns should be included in any SQL UPDATE statements.
Lazy	Specifies that this property should be fetched lazily when the instance variable is first accessed.
Many-to-Many operation side	Specifies the entry point when operating data in bi-directional many-to-many association. No matter the choice is RoleA or RoleB, the results are the same.

Defining Inheritance Mappings

ADO.NET and ADO.NET CF support the three basic inheritance mapping strategies:

- Table per class hierarchy
- Table per subclass
- Table per concrete class
- These strategies all follow the standard inheritance mapping definitions.

Generating Code for ADO.NET or ADO.NET CF

In order to generate code for ADO.NET or ADO.NET CF, you must have the .NET Framework 2.0 Visual Studio.NET 2005 or above installed:

1. Select **Tools > Check Model** to verify if there are errors or warnings in the model. If there are errors, fix them before continuing with code generation.
2. Select **Language > Generate C# 2 Code or Generate Visual Basic 2005 Code** to open the Generation dialog box:
3. Specify the root directory where you want to generate the code and then click the Options tab:

- [optional] To use DAL, set the Generate DAL sources option to true. For information about the standard C# and VB.NET generation options, see the *Object-Oriented Modeling* guide.
- Click OK to generate code immediately or Apply and then Cancel to save your changes for later.

Once generation is complete, you can use an IDE such as Visual Studio.NET 2005 to modify the code, compile, and develop your application.

Generating NHibernate Persistent Objects

NHibernate is a port of the Hibernate Core for Java to the .NET Framework. It handles persistent POCOs (Plain Old CLR Objects) to and from an underlying relational database.

All the common .NET idioms, including association, inheritance, polymorphism, composition, and the collections framework are supported. NHibernate allows you to express queries in its own portable SQL extension (HQL), as well as in native SQL, or with Criteria and Example objects.

PowerDesigner supports the design of .NET classes, database schema, and Object/Relational mapping (O/R mapping). Using these metadata, PowerDesigner can generate NHibernate persistent objects including:

- Persistent .NET classes (domain specific objects)
- NHibernate Configuration file
- NHibernate O/R mapping files
- DAL factory
- Data Access Objects (DAL)

Adding NHibernate Support

PowerDesigner provides support for generating for NHibernate through an extended model definition.

1. Verify that the current model has the target language C# 2.0 or Visual Basic 2005
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **O/R Mapping** sub-tab, select the **NHibernate xem**, and click **OK** to attach it to your model.
4. Click **OK** to close the List of Extended Model Definitions and return to your model.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

NHibernate Options

To set the database connection parameters and other NHibernate options, double-click the model name in the browser to open its property sheet, and click the NHibernate tab.

Option	Description
Dialect	Specifies the dialect, and hence the type of database. NHibernate Tag: dialect
Driver class	Specifies the driver class. NHibernate Tag: connection.driver_class
Connection String	Specifies the connection string. You can enter this by hand or click the ellipsis tool to the right of the field to use a custom dialog. For information about the provider-specific parameters used to build the connection string, see <i>Configuring Connection Strings</i> on page 693. NHibernate Tag: connection.url
Auto import	Specifies that users may use an unqualified class name in queries.

Option	Description
Default access	Specifies the default class attribute access type. This and the other package options, are valid for the whole model You can fine-tune these options for an individual package through its property sheet.
Specifies the default cascade	Specifies the default cascade type.
Schema name	Specifies the default database schema name.
Catalog name	Specifies the default database catalog name.
Show SQL	Specifies that SQL statements should be shown in the log. NHibernate Tag: show_sql
Auto schema export	Specifies the mode of creation from tables. NHibernate Tag: hbm2ddl.auto

Defining Class Mappings

There are two kinds of classes in NHibernate:

- Entity classes - have their own database identities, mapping files and life cycles
- Value type classes - depend on entity classes. Also known as component classes

NHibernate uses mapping XML files to define the mapping metadata. Each mapping file can contain metadata for one or many classes. PowerDesigner uses the following grouping strategy:

- A separate mapping file is generated for each single entity class that is not in an inheritance hierarchy.
- A separate mapping file is generated for each inheritance hierarchy that has a unique mapping strategy. All mappings of subclasses are defined in the mapping file. The mapping file is generated for the root class of the hierarchy.
- No mapping file is generated for a single value type class that is not in an inheritance hierarchy. Its mapping is defined in its owner's mapping file.

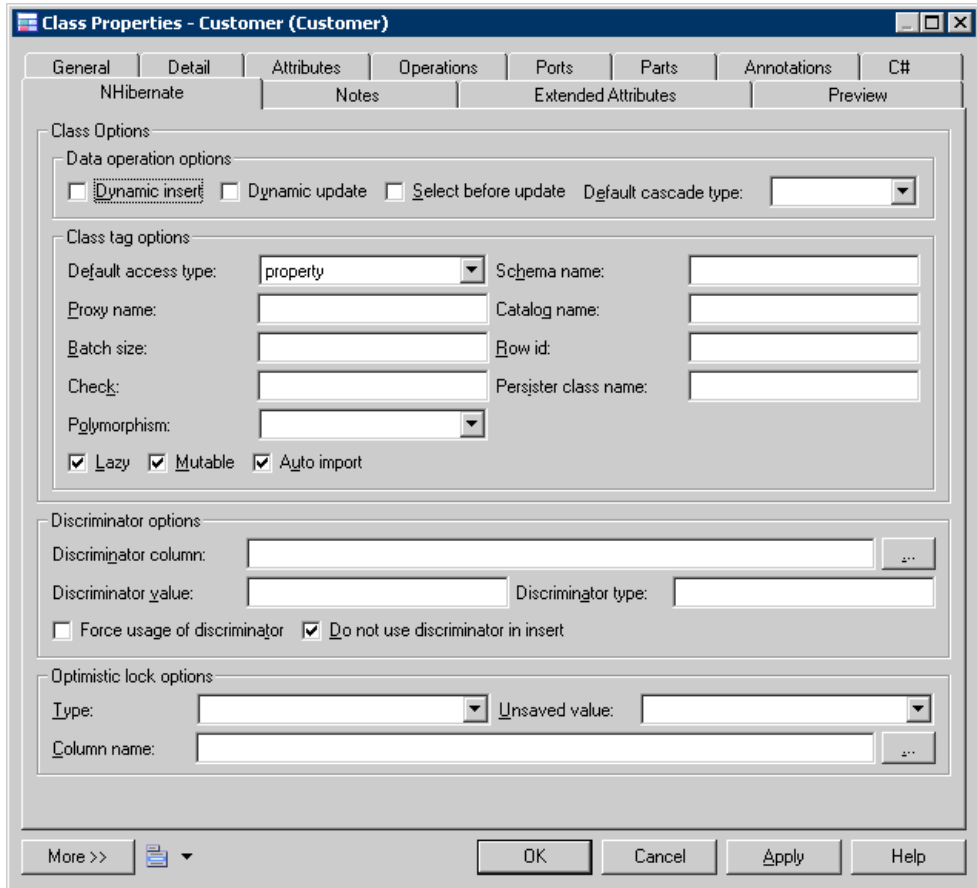

Classes can be mapped to tables or views. Since views have many constraints and limited functionality (for example they do not have primary keys and reference keys), some views cannot be updated, and the mappings may not work properly in some cases.

There are some conditions that need to be met in order to generate mapping for a specific class:

- The source can be generated. This may not be possible if, for example, the visibility of the class is private.
- The class is persistent.
- The generation mode is not set to Generate ADT (abstract data type) and Value Type.

- If the class is an inner class, it must be static, and have public visibility. NHibernate should then be able to create instances of the class.

NHibernate specific class mapping options are defined in the NHibernate tab of the class property sheet:

Option	Description
Dynamic insert	Specifies that INSERT SQL should be generated at runtime and will contain only the columns whose values are not null. NHibernate Tag: dynamic-insert
Dynamic update	Specifies that UPDATE SQL should be generated at runtime and will contain only the columns whose values have changed. NHibernate Tag: dynamic-update

Option	Description
Select before update	Specifies that NHibernate should never perform a SQL UPDATE unless it is certain that an object is actually modified. NHibernate Tag: select-before-update
Default cascade	Specifies the default cascade style. NHibernate Tag: default-cascade
Default access	Specifies the default access type (field or property) NHibernate Tag: default-access
Proxy name	Specifies an interface to use for lazy initializing proxies. NHibernate Tag: proxy
Batch size	Specifies a "batch size" for fetching instances of this class by identifier. NHibernate Tag: batch-size
Check	Specifies a SQL expression used to generate a multi-row check constraint for automatic schema generation. NHibernate Tag: check
Polymorphism	Specifies whether implicit or explicit query polymorphism is used. NHibernate Tag: polymorphism
Schema name	Specifies the name of the database schema. NHibernate Tag: schema
Catalog name	Specifies the name of the database catalog. NHibernate Tag: catalog
Row id	Specifies that NHibernate can use the ROWID column on databases which support it (for example, Oracle). NHibernate Tag: rowed
Persister class name	Specifies a custom persistence class. NHibernate Tag: persister
Lazy	Specifies that the class should be lazy fetching. NHibernate Tag: lazy
Mutable	Specifies that instances of the class are mutable. NHibernate Tag: mutable
Abstract class	Specifies that the class is abstract. NHibernate Tag: abstract

Option	Description
Auto import	Specifies that an unqualified class name can be used in a query NHibernate Tag: Auto-import
Discriminator column	Specifies the discriminator column or formula for polymorphic behavior in a one table per hierarchy mapping strategy. NHibernate Tag: discriminator
Discriminator value	Specifies a value that distinguishes individual subclasses, which are used for polymorphic behavior. NHibernate Tag: discriminator-value
Discriminator type	Specifies the discriminator type. NHibernate Tag: type
Force usage of discriminator	Forces NHibernate to specify allowed discriminator values even when retrieving all instances of the root class. NHibernate Tag: force
Do not use discriminator in insert	Forces NHibernate to not include the column in SQL INSERTs NHibernate Tag: insert
Optimistic lock type	Specifies an optimistic locking strategy. NHibernate Tag: optimistic-lock
Optimistic lock column name	Specifies the column used for optimistic locking. A field is also generated if this option is set. NHibernate Tag: version/ timestamp
Optimistic lock unsaved value	Specifies whether an unsaved value is null or undefined. NHibernate Tag: unsaved-value

Primary Identifier Mappings

Primary identifier mapping is mandatory in NHibernate. Primary identifiers of entity classes are mapped to primary keys of master tables in data sources. If not defined, a default primary identifier mapping will be generated, but this may not work properly.

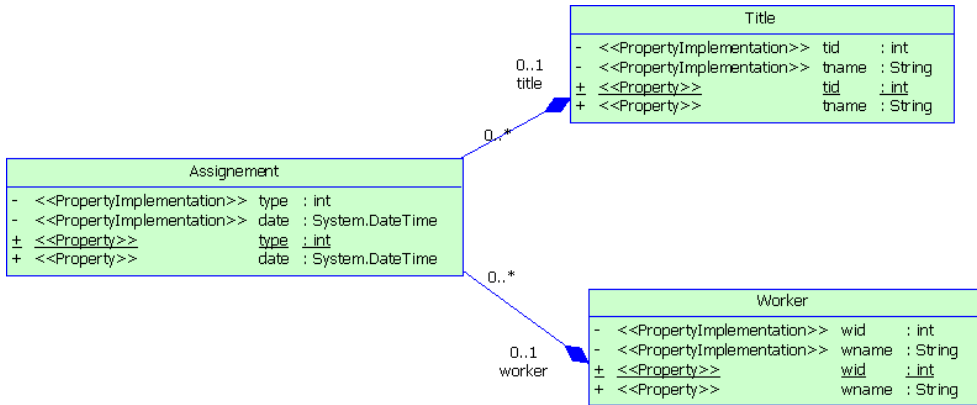

There are three kinds of primary identifier mapping in NHibernate:

- Simple identifier mapping -
- Composite identifier mapping
- Component identifier mapping

Mapped classes must declare the primary key column of the database table. Most classes will also have a property holding the unique identifier of an instance.

Composite Identifier Mapping

If a primary key comprises more than one column, the primary identifier can have multiple attributes mapped to these columns. In some cases, the primary key column could also be the foreign key column.

In the above example, the Assignment class has a primary identifier with three attributes: one basic type attribute and two migrated attributes. The primary identifier mapping is as follows:

```

<composite-id>
  < key-property name="Type" access="property">
    < column name="Type" sql-type="integer"
      not-null="true" />
  </key-property>
  <key-many-to-one name="title" access="property">
  </key-many-to-one>
  <key-many-to-one name="worker" access="property">
  </key-many-to-one>
</composite-id>
  
```

Component Primary Identifier Mapping

For more convenience, a composite identifier can be implemented as a separate value type class. The primary identifier has just one attribute with the class type. The separate class should be defined as a value type class. Component class mapping will be generated then.

In the example above, three name attributes are grouped into one separate class Name. It is mapped to the same table as Person class. The generated primary identifier is as follows:

```

<composite-id name="name" class="identifier.Name">
  <key-property name="firstName">
  
```

```

    <column name="name_firstName"
      sql-type="text" />
  </key-property>
  <key-property name="middleName">
    <column name="name_middleName"
      sql-type="text" />
  </key-property>
  <key-property name="lastName">
    <column name="name_lastName"
      sql-type="text" />
  </key-property>
</composite-id>

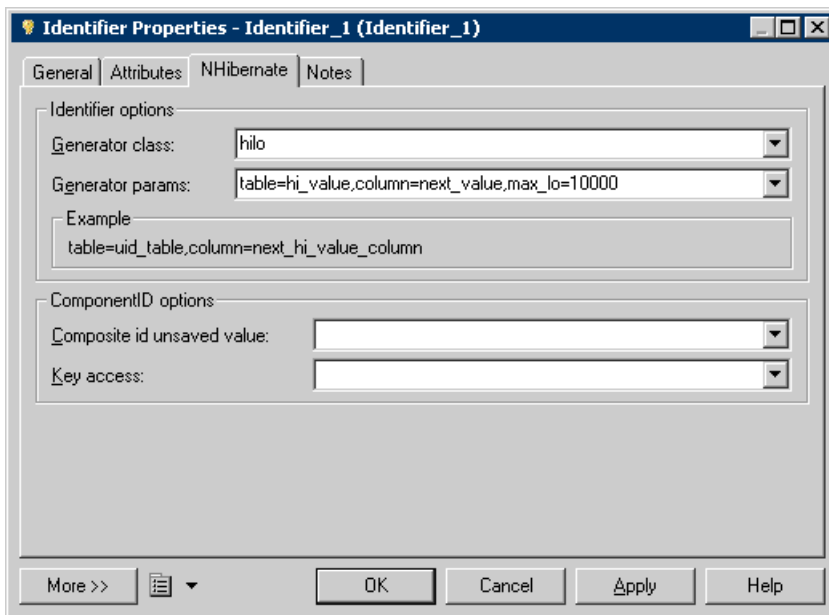

```

Note: The value type class must implement the `java.io.Serializable` interface, which implements the `equals()` and `hashCode()` methods.

Simple Identifier Mapping

When a primary key is attached to a single column, only one attribute in the primary identifier can be mapped. This kind of primary key can be generated automatically. You can define the generator class and parameters. There are many generator class types, such as increment, identity, sequence, etc. Each type of generator class may have parameters that are meaningful to it. See your NHibernate documentation for detailed information.

You can define the generator class and parameters in the NHibernate tab of the primary identifier property sheet. The parameters take the form of `param1=value1; param2=value2`.

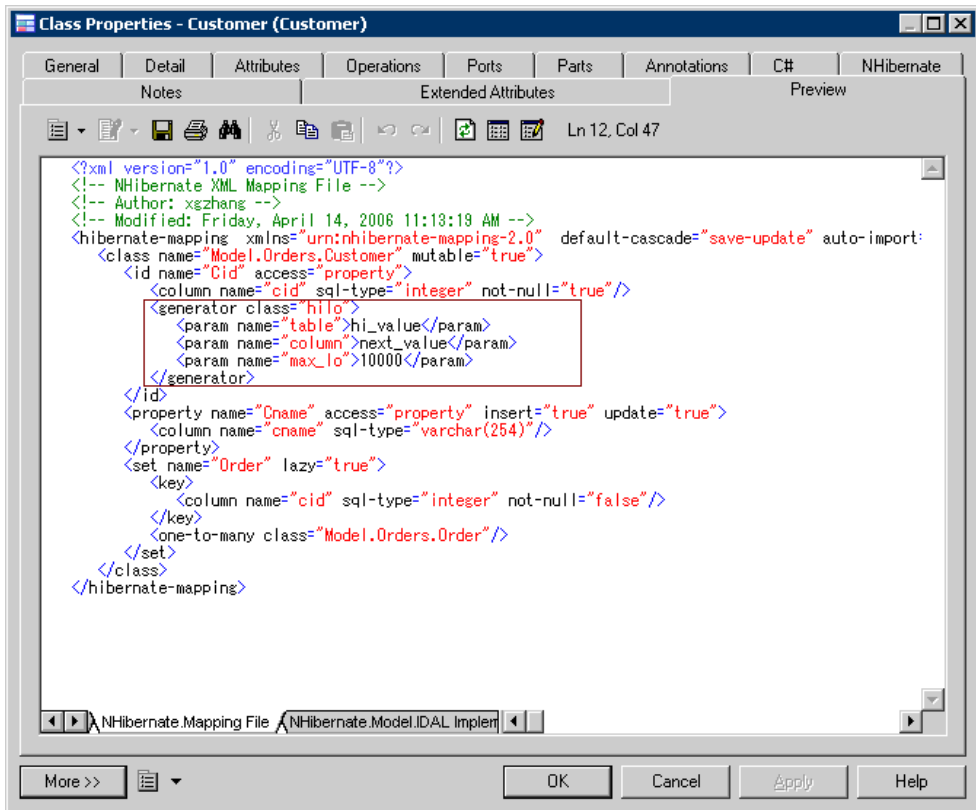

1. Open the class property sheet and click the Identifiers tab. Double-click the entry to open its property sheet.

- Click the NHibernate tab, select a generator class and define its parameters.

Example parameters:

- Select hilo in the Generator class list
- Enter "table=hi_value,column=next_value,max_lo=10000" in the Generator params box. You should use commas to separate the parameters.

- You can check the code in the Preview tab:

Note that, if there are several Primary identifier attributes, the generator is not used.

Attribute Mappings

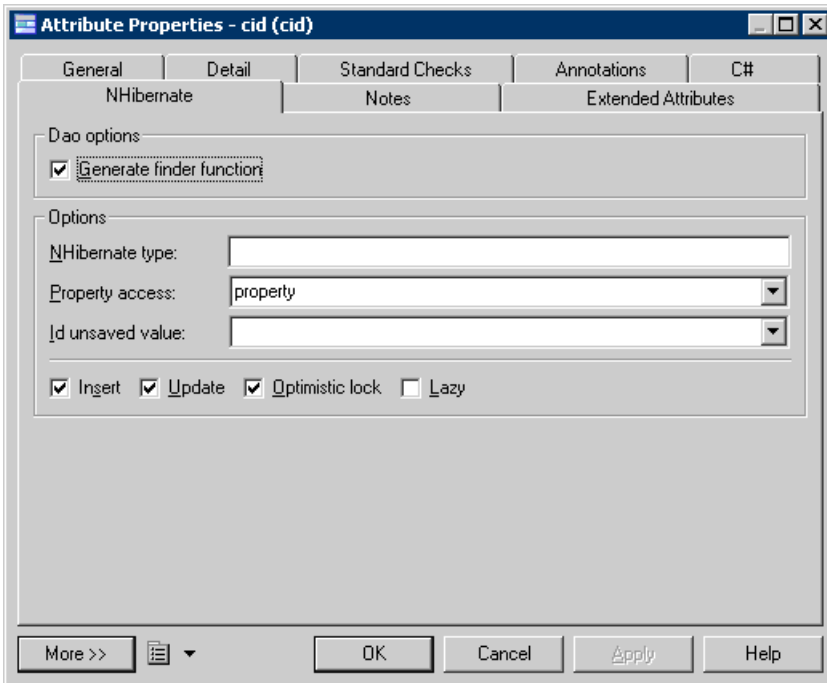

Attributes can be migrated attributes or ordinary attributes. Ordinary attributes can be mapped to columns or formulas. Migrated attributes do not require attribute mapping.

The following types of mapping are possible:

- Map attribute to formula - When mapping an attribute to a formula, you should ensure that the syntax is correct. There is no column in the source table of the attribute mapping.

- Component attribute mapping - A component class can define the attribute mapping as for other classes, except that there is no primary identifier.
- Discriminator mapping - In inheritance mapping with a one-table-per-hierarchy strategy, the discriminator needs to be specified in the root class. You can define the discriminator in the NHibernate tab of the class property sheet.

NHibernate-specific attribute mapping options are defined in the NHibernate tab of the Attribute property sheet.

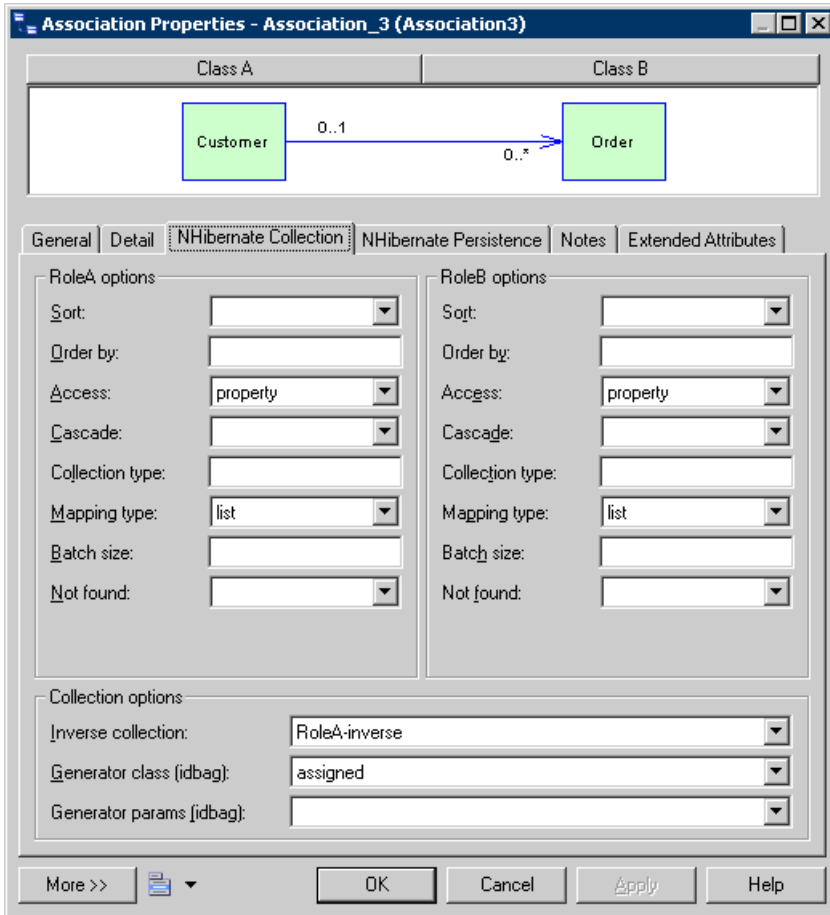

Option	Description
Generate finder function	Generates a finder function for the attribute.
NHibernate type	Specifies a name that indicates the NHibernate type.
Property access	Specifies the strategy that NHibernate should use for accessing the property value.
Id unsaved value	Specifies the value of an unsaved id.
Insert	Specifies that the mapped columns should be included in any SQL INSERT statements.
Update	Specifies that the mapped columns should be included in any SQL UPDATE statements.

Option	Description
Optimistic lock	Specifies that updates to this property require acquisition of the optimistic lock.
Lazy	Specifies that this property should be fetched lazily when the instance variable is first accessed (requires build-time byte code instrumentation).

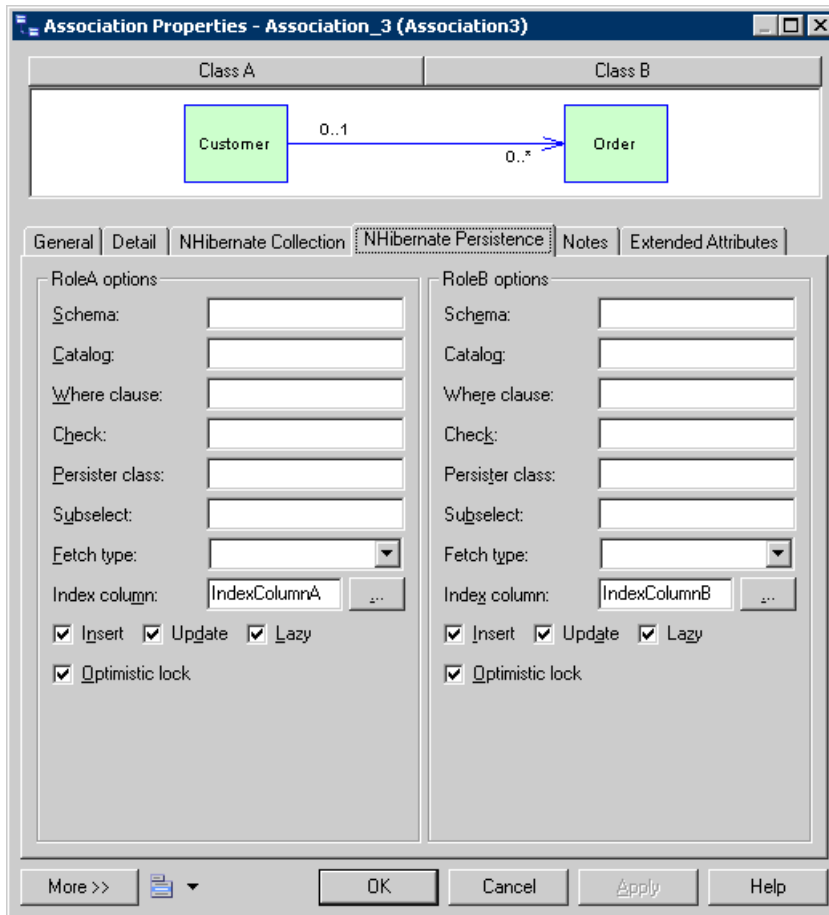

Defining Association Mappings

NHibernate supports one-one, one-to-many/many-to-one, and many-to-many association mappings. The mapping modeling is same with standard O/R Mapping Modeling. However, NHibernate provides special options to define its association mappings, which will be saved into <Class>.hbm.xml mapping file. PowerDesigner allows you to define standard association attributes like Container Type class, role navigability, array size and specific extended attributes for NHibernate association mappings.

1. Open the Association property sheet and click the NHibernate Collection tab.
2. Define the collection management options (see *Defining NHibernate Collection options* on page 689).

3. Select the NHibernate Persistence tab, and define the persistence options (see *Defining NHibernate Persistence options* on page 690).

Defining NHibernate Collection Options

The following options are available:

Option	Description
Sort	Specifies a sorted collection with natural sort order, or a given comparator class. NHibernate Tag: sort
Order by	Specifies a table column (or columns) that define the iteration order of the Set or bag, together with an optional asc or desc. NHibernate Tag: order-by
Access	Specifies the strategy Nhibernate should use for accessing the property value. NHibernate Tag: access

Option	Description
Cascade	Specifies which operations should be cascaded from the parent object to the associated object. NHibernate Tag: cascade
Collection type	Specifies a name that indicates the NHibernate type. NHibernate Tag: type
Batch size	Specifies the batch load size. NHibernate Tag: batch-size
Not found	Specifies how foreign keys that reference missing rows will be handled: ignore will treat a missing row as a null association. NHibernate Tag: not-found
Inverse collection	Specifies that the role is the inverse relation of the opposite role. NHibernate Tag: inverse
Mapping type	Specifies the collection mapping type NHibernate Tag: Set, Array, Map, or List.

Defining NHibernate Persistence Options

The following options are available:

Option	Description
Schema	Specifies the name of the schema. NHibernate Tag: schema
Catalog	Specifies the name of the catalog. NHibernate Tag: catalog
Where clause	Specifies an arbitrary SQL WHERE condition to be used when retrieving objects of this class. NHibernate Tag: where
Check	Specifies a SQL expression used to generate a multi-row check constraint for automatic schema generation. NHibernate Tag: check
Fetch type	Specifies outer-join or sequential select fetching. NHibernate Tag: fetch
Persister class	Specifies a custom persistence class. NHibernate Tag: persister

Option	Description
Subselect	Specifies an immutable and read-only entity to a database subselect. NHibernate Tag: subselect
Index column	Specifies the column name if users use list or array collection type. NHibernate Tag: index
Insert	Specifies that the mapped columns should be included in any SQL INSERT statements. NHibernate Tag: insert
Update	Specifies that the mapped columns should be included in any SQL UPDATE statements. NHibernate Tag: update
Lazy	Specifies that this property should be fetched lazily when the instance variable is first accessed. NHibernate Tag: lazy
Optimistic lock	Specifies that a version increment should occur when this property is dirty. NHibernate Tag: optimistic-lock
Outer join	Specifies to use an outer-join. NHibernate Tag: outer-join

Defining NHibernate Collection Container Type

NHibernate supports Set, Bag, List, Array, and Map mapping type, it restricts the container type. PowerDesigner does not support Map mapping type.

Collection Mapping Type	Collection Container Type
Set	Iesi.Collections.ISet
Bag	System.Collections.ICollection
List	System.Collections.IList
Array	<None>

You can input the container type manually, or select the needed mapping type, and PowerDesigner will automatically select the correct container type.

Defining Inheritance Mappings

NHibernate supports the two basic inheritance mapping strategies:

- Table per class hierarchy

- Table per subclass

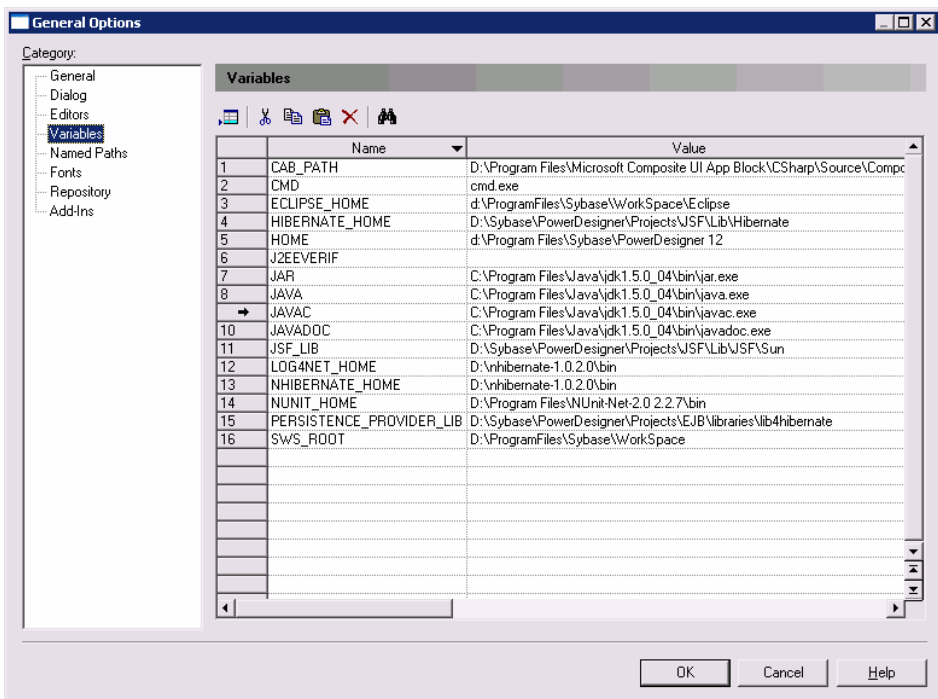

It does not support the "Table per concrete class" mapping strategy.

These strategies all follow the standard inheritance mapping definitions. However, a separate mapping file is generated for each inheritance hierarchy that has a unique mapping strategy. All mappings of subclasses are defined in the mapping file. The mapping file is generated for the root class of the hierarchy.

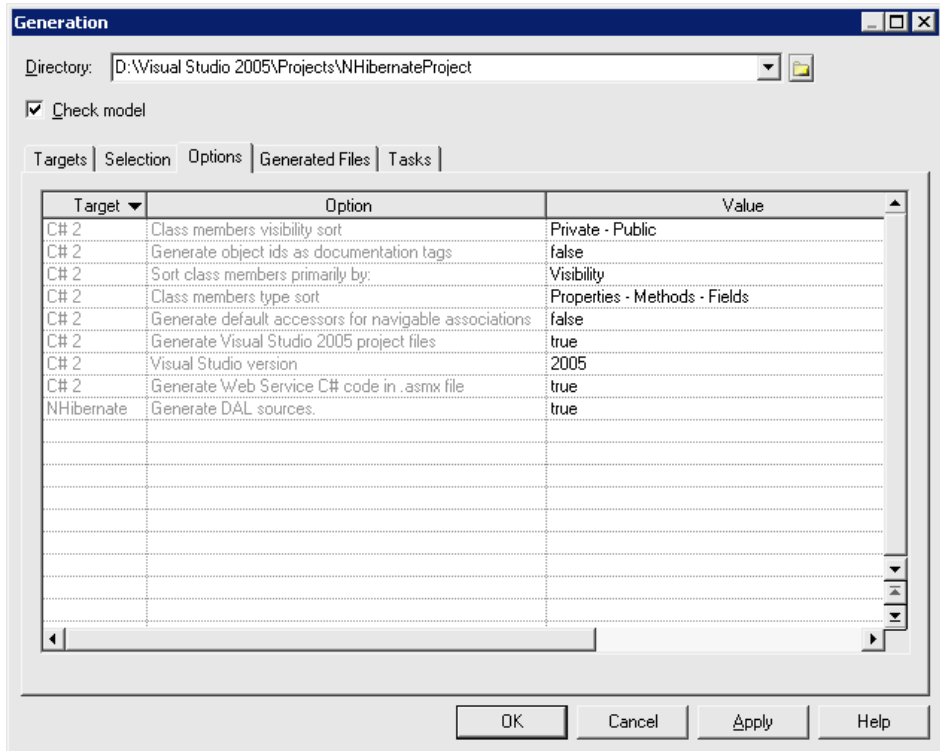

Generating Code for NHibernate

Before generating code for NHibernate, you must have NHibernate 1.0.2 or higher installed.

1. Select **Tools > Check Model** to verify if there are errors or warnings in the model. If there are errors, fix them before continuing with code generation.
2. Select **Tools > General Options**, and click the Variables node.

3. Add a variable NHIBERNATE_HOME and, in the value field, enter the NHibernate home directory path. For example, D:\nhibernate-1.0.2.0\bin.
4. Select **Language > Generate C# 2 Code or Generate Visual Basic 2005 Code** to open the Generation dialog box:
5. Specify the root directory where you want to generate the code, and then click the Options tab:

6. [optional] To use DAL, set the Generate DAL sources option to true. For information about the standard C# and VB.NET generation options, see the relevant chapters.
7. Click OK to generate code immediately or Apply and then Cancel to save your changes for later.

Once generation is complete, you can use an IDE such as Visual Studio.NET 2005 to modify the code, compile, and develop your application.

Configuring Connection Strings

PowerDesigner supports multiple types of database connection with each of the .NET frameworks.

Each connection requires a different set of parameters, which can be entered by hand in the Connection String field of the ADO.NET or NHibernate tab, or through custom dialogs accessible via the ellipsis tool to the right of this field.

Configuring a Connection String from the ADO.NET or ADO.NET CF Tab

You configure a connection string from the ADO.NET or ADO.NET CF tab as follows:

1. Select a data provider.
2. Click the ellipsis button to open a provider-specific connection string dialog.
3. [ADO.NET only] Enter the necessary parameters and click Test Connection to validate them.
4. Click Apply to Connection String and then Close to return to the ADO.NET or ADO.NET CF tab.

Configuring a Connection String from the NHibernate Tab

You configure a connection string from the NHibernate tab as follows:

1. Select a dialect and driver class.
2. Click the ellipsis button to open a provider-specific connection string dialog.
3. Enter the necessary parameters and click Test Connection to validate them.
4. Once the connection tests correctly, click Close to return to the NHibernate tab.

OLEDB Connection String Parameters

The following parameters are required to configure an OLEDB connection string:

- | Option | Description |
|------------------------------------|---|
| Data provider | Specifies the data provider from the list |
| Server or file name | Specifies the database server or file name. |
| User name | Specifies the database user name. |
| Password | Specifies the database user password. |
| Use Windows NT integrated security | Specifies to use Windows NT integrated security. |
| Allow saving password | Specifies whether to allow saving password or not |
| Initial catalog | Specifies database's initial catalog. |

ODBC Connection String Parameters

The following parameters are required to configure an ODBC connection string:

- | Option | Description |
|------------------|---------------------------------------|
| ODBC source name | Specifies the ODBC source name |
| User name | Specifies the database user name. |
| Password | Specifies the database user password. |

Microsoft SQL Server and Microsoft SQL Server Mobile Edition Connection String Parameters

The following parameters are required to configure a Microsoft SQL Server and Microsoft SQL Server Mobile Edition connection string:

- | Option | Description |
|---------------------|---|
| Server name | Specifies the server name. |
| User name | Specifies the database user name. |
| Password | Specifies the database user password. |
| Authentication type | Specifies authentication type, Use SQL Server Authentication, or Use Windows Authentication |
| Database name | Specifies the database name |
| Database file name | Specifies the database's file name. |
| Logical name | Specifies the logical name for the database file. |

Oracle Connection String Parameters

The following parameters are required to configure an Oracle connection string:

- | Option | Description |
|-------------|---------------------------------------|
| Server name | Specifies the server name. |
| User name | Specifies the database user name. |
| Password | Specifies the database user password. |

Generating Unit Tests

If there are many persistent classes, it can be difficult to test them all to prove that:

- The mappings are correctly defined
- The CRUD (Create, Read, Update, Delete) options work
- The find methods work
- The navigations work

Usually, developers have to develop unit tests or user-interfaces in order to test these objects. PowerDesigner can automate this time-consuming process by using the NUnit or Visual Studio Test System (VSTS) to generate the unit test classes.

Some conditions must be met to unit test for a class:

- Mapping of the class should be defined.
- The class can be instantiated. Unit test classes cannot be generated for abstract classes.
- The class is not a value type.
- The Mutable property is set to true. If Mutable is set to false, the class can not be updated or deleted.
- The class has no unfulfilled foreign key constraints. If any foreign key is mandatory, the parent class should be reachable (navigable on the parent class side) for testing.

You can run the tests using NUnit or Visual Studio Test System.

Add Unit Test Support

PowerDesigner provides a UnitTest.NET extended model definition to generate unit test files.

1. Verify that the current model has the target language C# 2.0 or Visual Basic 2005, and includes an extended model definition for either ADO.NET, ADO.NET CF, or Nhibernate.
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **Unit Test** sub-tab, select the `UnitTest.NET` or `UnitTest.NET CF xem`, and click **OK** to attach it to your model.
4. Click **OK** to close the List of Extended Model Definitions and return to your model.

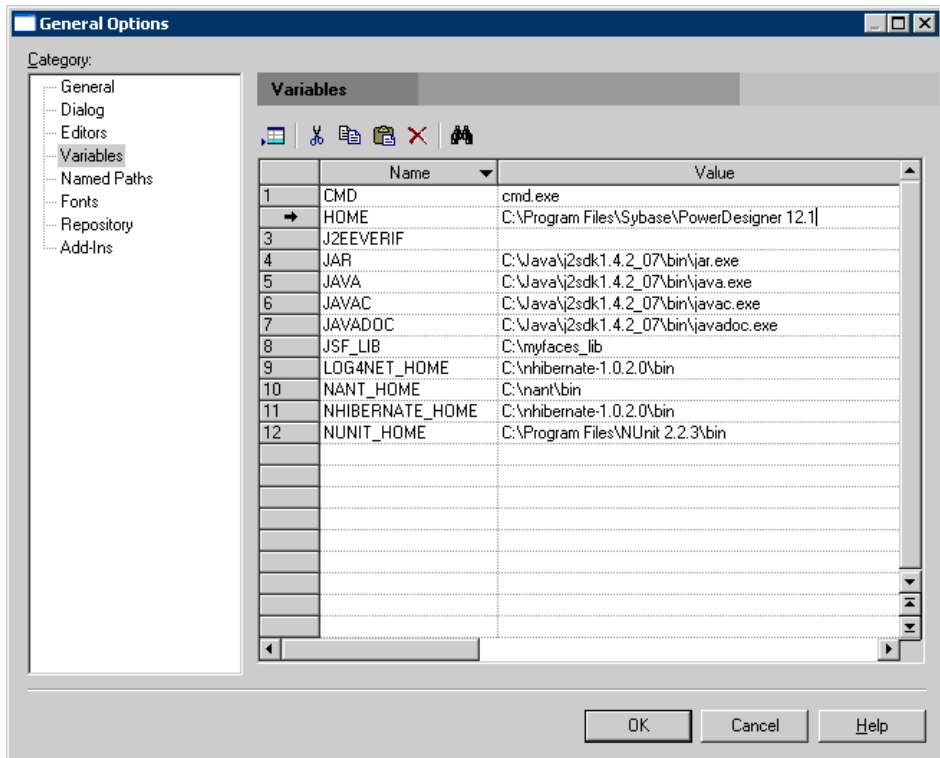

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

Generating Code for Unit Testing

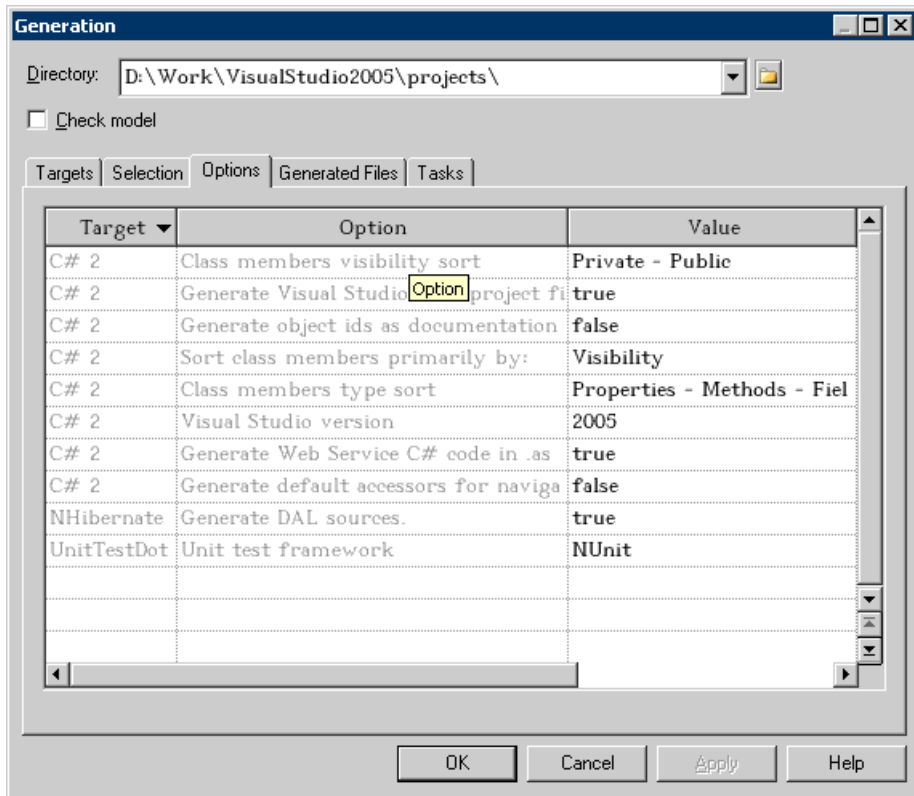

You generate Code for Unit Testing as follows:

Before generating code for UnitTest, you must have NUnit 2.2.3 or higher installed (available at <http://www.nunit.org>).

1. Select **Tools > Check Model** to verify if there are errors or warnings in the model. If there are errors, fix them before continuing with code generation.
2. Select **Tools > General Options**, and click the Variables node.
3. Add a variable NUNIT_HOME and, in the value field, enter the NUnit home directory path. For example, D:\NUnit2.2.3\bin. Add a variable LOG4NET_HOME in the same way if log4net is going to be used for logging.

4. Select **Language > Generate C# 2 Code** or **Generate Visual Basic 2005 Code** or **Generate Visual Basic 2005 Code** to open the Generation dialog box.
5. Specify the root directory where you want to generate the code, and then click the Options tab:

6. Select a UnitTest framework in "Unit test framework". You can choose between NUnit or Visual Studio Team Test.
7. Click on OK to generate code immediately or Apply, and then Cancel to save your changes for later.

Differences Between NUnit and Visual Studio Team Test (VSTS)

Most code generated for these two UnitTest frameworks is very similar. The main differences are:

- Team Test use different attributes with NUnit in test class, such as [TestClass()] to [TestFixture] and [TestMethod()] to [Test] etc.
- AllTests file is not generated because all tests will be run in Visual Studio gui or command prompt.
- Log4net is replaced by test result .trx file that can be opened in Test Result window in Visual Studio.

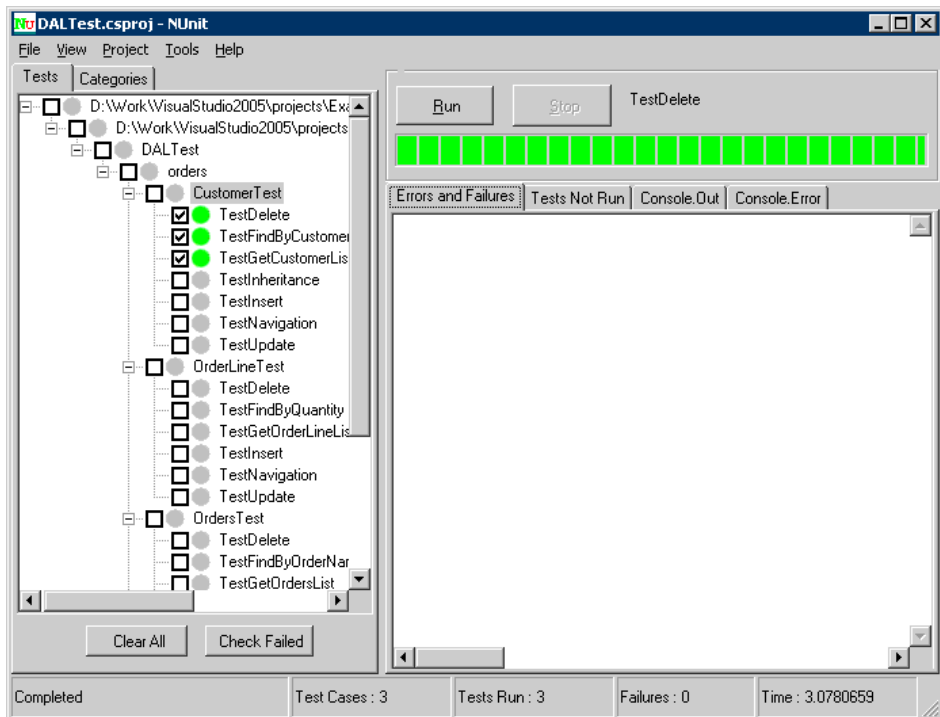

Running NUnit Unit Tests

After generating your test code, you can run it in one of three ways:

- Run in Nunit - NUnit has two different ways to run your test cases. The console runner, `nunit-console.exe`, is the fastest to launch, but is not interactive. The GUI runner, `nunit-gui.exe`, is a Windows Forms application that allows you to work selectively with your test cases and provides graphical feedback.

NUnit also provide Category attribute, which provides an alternative to suites for dealing with groups of tests. Either individual test cases or fixtures may be identified as belonging to a particular category. Both the GUI and console test runners allow specifying a list of categories to be included in or excluded from the run. When categories are used, only the tests in the selected categories will be run. Those tests in categories that are not selected are not reported at all.

- Nunit GUI - The `nunit-gui.exe` program is a graphical runner. It shows the tests in an explorer-like browser window and provides a visual indication of the success or failure of the tests. It allows you to selectively run single tests or suites and reloads automatically as you modify and re-compile your code.

As you can see, the tests that were not run are marked with a grey circle, while those that were run successfully are colored green. If any tests had failed, they would be marked red.

- Nunit Console - The nunit-console.exe program is a text-based runner and can be used when you want to run all your tests and don't need a red/yellow/green indication of success or failure. It is useful for automation of tests and integration into other systems. It automatically saves its results in XML format, allowing you to produce reports or otherwise process the results.

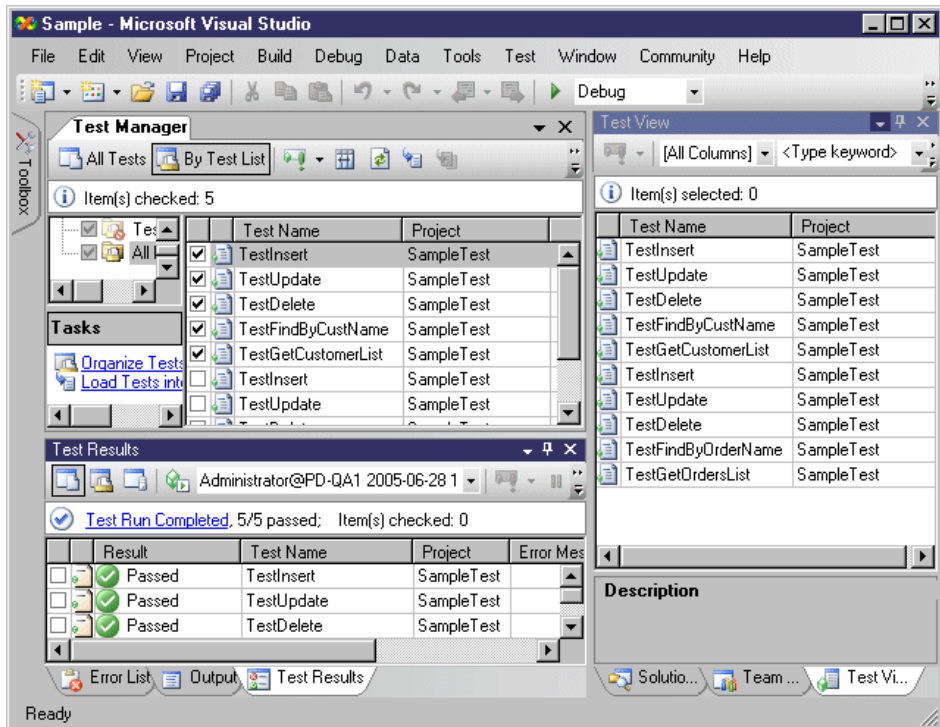

Running Visual Studio Test System Unit Tests

The Visual Studio Team System Team Test tools offer a number of ways to run tests, both from the Visual Studio integrated development environment (IDE) and from a command prompt.

Running Tests in Visual Studio.NET 2005 IDE

You run tests in Visual Studio.NET 2005 IDE as follows:

1. Use the Test Manager or Test View window. You can also rerun tests from the Test Result window.
2. In the Test Manager window, select tests by selecting the check boxes in the test's row, and then either click Run Tests on the Test Manager toolbar or right-click the selected tests and then click Run Checked Tests.
3. In the Test View window, select the tests you want to run and then click Run Tests on the Test View toolbar, or right-click, and select Run Selection.

Running Tests from the Command Line

You run tests from the command line as follows:

1. Open the Visual Studio command prompt
2. Either navigate to your solution folder directory or, when you run the MSTest.exe program in step, specify a full or relative path to the metadata file or to the test container.
3. Run the MSTest.exe program

Generating Windows or Smart Device Applications

The Composite UI Application Block (CAB) helps you build complex user interface applications that run in Windows. It provides an architecture and implementation that assists with building applications by using the common patterns found in line-of-business client applications. The current version of the Composite UI Application Block is aimed at Windows Forms applications that run with the Microsoft .NET Framework 2.0.

PowerDesigner can automatically generate UI files based on CAB according to the persistent framework you select, such as NHibernate or ADO.NET. With persistent classes, DAL, BLL and UI files based on CAB generated by PowerDesigner, you can quickly build Windows application without writing repetitive code.

Using this Windows application, you can test persistent objects with your own data. You can also improve the generated files and change the layout as you like in Visual Studio .NET 2005.

Adding Windows or Smart Device Application Support

PowerDesigner provides both Windows Application and Smart Device Application Extended Model Definitions, which allow you to generate UI files.

Adding Windows Application Support

PowerDesigner provides support for Windows applications through an extended model definition.

1. Verify that the current model has the target language C# 2.0 or Visual Basic 2005, and includes an extended model definition for either ADO.NET or NHibernate.
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **User Interface** sub-tab, select the `Windows Application.xem`, and click **OK** to attach it to your model.
4. Click **OK** to close the List of Extended Model Definitions and return to your model.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

Adding Smart Device Application Support

PowerDesigner provides support for Smart Device Applications in the form of an extended model definition.

1. Verify that the current model has the target language C# 2.0 or Visual Basic 2005, and includes an extended model definition for ADO.NET CF.
2. Select **Model > Extended Model Definitions**, and click the **Import** tool.
3. Click the **User Interface** sub-tab, select the Smart Device Application xem, and click **OK** to attach it to your model.
4. Click **OK** to close the List of Extended Model Definitions and return to your model.

Note: You can also attach an XEM at model creation time by clicking the **Select Extensions** button on the **New Model** dialog.

Specifying an Image Library

Your forms will probably use some images as icons. PowerDesigner provides a default image library, which it uses by default for Windows applications. You can also specify your own image library.

1. Open the model property sheet, and click the Window Application tab.
2. Specify a path to your image library, and then click OK to return to the model.

Controlling the Data Grid View

You can specify the length of your ADO.NET CF datagrid views.

1. Open the model property sheet, and click the Smart Device Application tab.
2. Specify the number of rows, and then click OK to return to the model.

Defining Attributes Display Options

You can define attribute-level options for presentation style.

1. Open Attribute Property sheet, and select the Windows Application tab.
2. Set the appropriate options and then click OK

The following options are available:

Option	Description
Control Type	You can choose TextBox or Comobox as input control
Display as foreign key label	Specifies to display the current attribute as a foreign key label in combo boxes, instead of the foreign key. For example, select this option for the product name attribute to use it as foreign key label instead of the product id.

Defining Attribute Validation Rules and Default Values

PowerDesigner provides validation and default values for the edit boxes in the Create, Find, ListView, and DetailView forms.

1. Open the attribute property sheet, and click the Standard Checks tab.
2. [optional] Define minimum value and maximum values to control the value range.
3. [optional] Define a default value. A string value must be enclosed in quotes. You can also define the Initial value in the Details tab.
4. [optional] Define a list of values. PowerDesigner will automatically generate a combo box that includes these values.
5. Click OK to return to the model.

Generating Code for a Windows Application

Before generating code for Windows Application, you need to install CAB (available from <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dnpag2/html/cab.asp>). Check for the following required files in your installation directory:

- Microsoft.Practices.CompositeUI.dll
 - Microsoft.Practices.CompositeUI.WinForms.dll
 - Microsoft.Practices.ObjectBuilder.dll
1. Select **Tools > Check Model** to verify if there are errors or warnings in the model. If there are errors, fix them before continuing with code generation.
 2. Select **Tools > General Options**, and click the Variables node.
 3. Add a variable CAB_PATH with the value of your installation directory
 4. Select **Language > Generate C# 2.0 Code or Generate Visual Basic 2005 Code** to open the Generation dialog box.
 5. Specify a target directory, and then click OK to begin generation.

The following files will be generated:

- Domain files (persistent classes, mapping files)
- DAL files (database connection file and data access files)
- A solution file and project files
- A login dialog
- Forms for persistent classes
- Controller files

For each persistent class, PowerDesigner generates:

- A find dialog for searching objects
- A list view form for displaying find results

- A detail view form for displaying object's detailed information
- A create view form for creating new objects

You can deploy or edit a Windows application in an IDE, such as Visual Studio .NET 2005.

Generating Code for a Smart Device Application

Before generating a smart device application, you must:

- Ensure that you have attached the ADO.NET Compact Framework (and, if you want to generate unit tests, UnitTest.NET Compact Framework) extended model definitions (see *Adding ADO.NET or ADO.NET CF support* on page 669).
- Set any appropriate model properties on the ADO.NET CF and Application tabs, including a functioning connection string (see *ADO.NET and ADO.NET CF options* on page 669).
- Specify appropriate values for the following variables (select **Tools > General Options**, and click the Variables category):
 - CFUT_HOME – if using Microsoft Mobile Client Software Factory CFUnitTester
 - ASANET_HOME – if using Sybase ASA. Specifies the location of iAnywhere.Data.AsaClient.dll.
 - SQLSERVERMOBILENET_HOME – if using Microsoft SQL Server Mobile Edition. Specifies the location of System.Data.SqlServerCe.dll
 - ULTRALITENETCE_HOME – if using Sybase UltraLite. Specifies the location of ulnet10.dll
 - ULTRALITENET_HOME – if using Sybase UltraLite. Specifies the location of iAnywhere.Data.UltraLite.dll and en\iAnywhere.Data.UltraLite.resources.dll

Generating Code

You generate code as follows:

1. Select **Tools > Check Model** to verify that there are no errors in the model. If there are errors, fix them before continuing with code generation.
2. Select **Language > Generate C#2 Code or Generate Visual Basic 2005** to open the Generation dialog box.
3. Specify the root directory where you want to generate the code and then click the Options tab.
4. Specify any appropriate options and then click OK to generate code immediately or Apply and then Cancel to save your changes for later.

Once you have generated your code, you can deploy it:

Deploying Code to a Smart Device

You deploy code to a smart device as follows:

1. Compile your generated code in Visual Studio.
2. Deploy the start up project, i.e. the <model>Test project or User Interface project
3. Deploy the SystemFramework project separately with the database file and required DLLs (such as ulnet10.dll for UltraLite support).

Testing the Application on the Device

You test the Application on the Device as follows:

1. If you have generated and deployed the user interface projects to the device, you can run them and test the application by inputting some data.
2. If you have generated for 'Microsoft Mobile Client Software Factory', you can run the unit tests by clicking GuiTestRunner.exe in the deployment folder in the device. The exe file and its references can be copied from the Microsoft Mobile Client Software Factory installation folder.
